(54) Title: A PORTABLE COMMUNICATION DEVICE AND METHOD

(57) Abstract: A portable communication device (1) has a microphone (5) and a processing device for receiving a handwritten message from a user and converting the received information into digital data. The processing device is operatively connected to the microphone (5), a keypad (6), and necessary means for normal operation of the communication device (1), so that sound caused by a user may be detected by the microphone (5) and forwarded, in electric form, to the processing device. The sound is recognised and either transformed into text on the display (4), used for moving a cursor on the display (4) or used for executing commands that control desired functions in the communication device (1).

A PORTABLE COMMUNICATION DEVICE AND METHOD

Field of the Invention

5 The present invention relates to a portable communication device with a microphone, the device further comprising a processing device, which works as a controller, for receiving a hand-written message from a user and converting the message into digital data.
10 Furthermore, the present invention relates to a method of detecting sound by the microphone and converting the sound into digital data.

Description of the Prior Art

15 In a communication device according to the above, such as a mobile telephone, or a personal data organizer, the common way of entering information is by using a keyboard. The same key on the keyboard is often used to enter several letters, and by combining
20 different keys and sequences different kind of messages can be entered.

 Another solution is to use a touch screen as an input device. Text can be written by hand on the screen and the letters recognised using software, or the touch
25 screen can be used for entering commands.

 Viewing of a large screen in small equipment can be done by using a micro-display.

 Another method of entering text into a stylus-based computer is disclosed in an On-line Quikwriting
30 Applet (<http://www.mrl.nyu.edu/perlin/demos/quikwriting.html>), developed by Ken Perlin, and published at the 11th annual ACM symposium, UIST 98 conference in California, p. 215-216. This method uses a touch screen, and the display has a specific design that defines different areas for
35 different characters. The characters are entered by moving a tip of an object in different sequences of

movement on the display, wherein each sequence defines a respective character.

Yet another solution of entering messages into a device is disclosed in US-A-3909785, wherein a pad or data surface has several defined character regions, each region having several defined sectors corresponding to digital coordinates that define different characters to be entered. These are entered by a needle or pen that emits sound energy pulses. The sound energy pulses are continuously detected, whereby the sectors being passed by the pen are identified and yield a respective character.

The main problem with the first mentioned solution is that the keyboard and the display are often very small. There are normally not enough keys for the whole alphabet, and several keys have to be pressed in order to input a single letter. The second solution with a touch screen on top of the display gives a lower contrast of the display and makes the display thicker and more expensive. Small displays also make it difficult to get a high resolution when a touch screen is being used with a portable device, and when using a micro-display a touch screen can not be used as input. The third solution uses an extended display, which increases the size and the cost for the device. The fourth solution involves a big unpractical display, and a specific pen or needle can only be used for entering characters, whereby the access to the device for another user without this specific pen is limited, and if the pen is forgotten the pad or data surface is useless.

Summary of the Invention

The object of the present invention is to provide a communication device with a possibility of entering hand-written messages easier and quicker.

This object is achieved for a portable communication device comprising a microphone and a processing device for receiving a message hand-written by a user on a surface of the device and converting the message into digital data. The processing device is
5 operatively connected to the microphone, so that different sounds caused by movement over different patterns and/or textures on a surface of the communication device when the user is hand-writing on
10 said surface may be acoustically detected by the microphone and forwarded, in electric form, to the processing device.

The movement of e g a pen or stylus over different combinations of said patterns and/or textures on the
15 surface corresponds to different text inputs or commands.

Preferably, a surface on the communication device has a specific design, wherein the surface is divided into several areas, which have sub patterns for creating
20 specific sounds when e g the pen or the stylus in contact with the surface moves against these sub patterns.

By providing the communication device with a cover, which has a specific surface, and the processing
25 device according to the invention, the following advantages are obtained. Input of information is simplified by not having to use the small and unpractical keys, thereby avoiding the time consuming pressing of keys. Notes and messages may thereby be
30 entered into the device easier and quicker. Commands for different functions can also be entered and executed with sound recognition. Furthermore, there will be no significant extra cost to include a processing device in a communication device that already comprises a
35 microphone, since all hardware is already installed. Any

fairly sharp object can also be used for entering messages.

The object of the invention has also been achieved by a method of detecting and recognising sound by means of the microphone together with the processing device, and converting the sound into digital data. The digital data may be forwarded to the display of the communication device or used for executing commands that control the communication device.

Other objects, features and advantages of the present invention are described in the subsequent detailed disclosure, and in the drawings as well as in the appended claims.

Brief Description of the Drawings

The present invention will now be described in further detail, reference being made to the accompanying drawings, in which:

FIG 1 is a perspective view showing a communication device;

FIG 2 is a perspective view showing a communication device in a position, where information can be entered on a cover according to the invention;

FIG 3 is a front view showing a preferred embodiment of a surface on a cover according to the invention;

FIG 4 is a frontview showing a preferred embodiment of a surface on a cover according to the invention;

FIG 5 is a view in section showing a preferred embodiment of a pattern on a surface according to the invention;

FIG 6 is a view in section showing another preferred embodiment of a pattern on a cover according to the invention;

FIG 7 is a view in section showing yet another preferred embodiment of a pattern on a cover according to the invention;

FIG 8 is a view in section further showing another preferred embodiment of a pattern on a cover according to the invention; and

FIG 9 is a flow chart showing a method of detecting, recognising, converting and entering data according to the invention into a communication device.

10

Detailed Description of the Invention

FIGS 1-2 illustrate a communication device 1 with a cover 3. FIGS 3-4 show two different embodiments of a surface 3' on the cover 3. Preferably, the communication device is a handheld device for entering messages into it or commands for controlling it, such as a mobile or cellular telephone. The device comprises a casing 2, the cover 3, a display 4, at least one microphone 5, a keypad 6, an antenna 8, loudspeaker openings 9, and a processing device, which is operatively connected to the display 4, the microphone 5 and the keypad 6. More than one microphone 5 could be used for a more accurate detection of sound and position of a tip 7 of a pen, a stylus, or a finger nail during handwriting.

The processing device comprises a controller (such as a central processing unit (CPU), a digital signal processor (DSP) or a programmable logic array (PLA)) together with a memory (such as an electrically erasable programmable read-only memory (EEPROM), a flash memory or similar means) and a set of program instructions stored in the memory and executable by the controller. Alternatively, the processing device could be realized solely in hardware, for instance as an application-specific integrated circuit (ASIC), discrete components or other components fulfilling the demands.

35

In FIGS 1 and 2, the communication device 1 has a movable flip or cover 3 for protecting the keypad 6 against damage and unintentional input. The cover 3 can be opened, thereby supporting a pen 7 or another object with a fairly sharp tip, such as a finger nail, when it is being used for handwriting on the communication device 1. The microphone 5 is preferably placed in the cover 3 close to a position where a user's mouth would be placed during use of a telephone mode, but can also be placed on the cover 3 at point 5', alone or with any number of microphones, closer to the communication device 1, or even in the casing 2 of the device 1 adjacent point 5", or in any other location in the device 1. This gives a more accurate detection of the sound due to a triangularity effect between several cooperating microphones instead of just one microphone.

The user can either use a pen 7 or another sharptipped object when writing by hand. The sound caused by the user during movement of the pen 7 against the cover 3 is registered by the microphone 5 and forwarded, in electric form, to the processing device. The sound, in electric form, is recognised by means of the processing device and suitable software. The sound is converted into digital data, representing e g a cursor movement or an entered text, and is forwarded to the display 4 of the communication device 1 by means of the processing device. The sound, in the form of digital data, can also be used as commands for executing desired functions and controlling the communication device 1. To facilitate the accuracy in registration of the sound, the cover 3 can be made slightly rugged and/or embossed in specific areas so that different patterns create different and distinct sounds, whereby the sound may be more easily recognised.

In FIG 3 a preferred embodiment of a surface 3' on the cover 3 is shown. The surface 3' is divided into several areas 3a, 3b, as shown in FIGS 3 and 4. The surface 3' consists of at least one area 3a in the centre and at least one outer sub area 3b surrounding the centre area 3a. The sub areas 3a and 3b are intended to define which characters to be entered when writing a message by hand. This is done by arranging a specific sub pattern 3" for each sub area 3b between the centre area 3a and its adherent sub area 3b. This means that a respective character, corresponding to each sub area 3b and its sub pattern 3", is entered by moving a tip 7 of a fairly sharp object twice over the sub pattern 3" in two different directions. The surface 3' could also be arranged on any other separate substantially planar surface, that is operatively connected to the processing device of the communication device 1, such as e g a separate pad, a table or any other handheld device for entering text or commands.

The most important when entering a hand-written message into the device 1 is that the movement of the tip 7 has to start and end in the centre area 3a. The passing of the different sub patterns 3" defines the desired character to be entered into the communication device 1 due to the specific sound caused when the tip 7, in contact with the surface 3', passes over a respective sub pattern 3". The start movement out of the centre area 3a past the specific sub pattern 3", and into the first outer sub area 3b, defines from which group of characters a desired character to be entered is chosen. The second movement from the first sub area 3b to another sub area, and past its sub pattern 3" back into the centre area 3a, defines the position of the desired character to be entered from the chosen group of

characters. This means that a character can be entered in one continuous movement without lifting the tip 7.

The tip 7 can be moved with different velocity and pressed against the surface 3' with various force by different users. The tip 7 can also be made of different materials, i e harder or softer. The processing device has an optional function, that can recognise the sound, and forwards the right information independent of what kind of tip 7 being used or with which force the user presses the tip 7 against the surface 3'. This function is a teaching mode, which is entered by pressing a key 6. The teaching of the processing device is done, after initiating this mode, by a movement of the tip 7 against a specific sub pattern 3" on the surface 3'. The sound created by this movement over the specific sub pattern 3" is detected, registered, and stored for later use as reference sound.

If a character to be entered can not be found in any of the sub areas 3b, other groups of characters can be chosen by moving the tip 7 in and out from the centre area 3a, i e back and forth over one or two specific sub patterns 3", or by tapping one or more times on the cover 3, or alternatively by pressing a key on the keypad 6. This change of character groups can be done by using the processing device for recognition of the sound caused by movement or tapping on the surface, or for recognition of the pressing of keys. The change can be indicated by a symbol or symbols on the display 4 of the device 1 and may show which group of characters are going to be used for entering the desired information. Any sub pattern can be defined to control the change between different character groups by means of symbols on the surface of the cover 3, and these symbols can also be presented simultaneously on the display 4 of the communication device 1.

These symbols can be designed in many ways, e g as circles, squares, triangles, stars, punctuation marks, or have any other form and can be defined to have different functions, e g changing the selectable
5 character groups from capital letters to small letters, or to figures, or alternatively to parentheses, or for executing different commands. A preferred group of symbols is a square initiating a stop, a circle, a triangle pointing upwards initiating activation of a
10 mode for entering upper cases or lower cases, a triangle pointing to the right for entering space, and a third triangle pointing to the left for deleting the last written character.

Preferably, as shown in FIGS 3 and 4, the surface
15 3' has eight outer sub areas 3b. Each sub area 3b has a sub pattern 3", which consists of at least one groove or rib for creating a specific sound when the tip 7 passes over it. This sound has to be unique for each sub area 3b, whereby each of the sub patterns 3" has a different
20 pattern consisting of a different number of grooves or ribs arranged in different combinations with different mutual distances, preferably eight different patterns of ribs A, B, C, D, E, F, G and H, shown in more detail in FIGS 5, 6, 7 and 8. Each of the sub areas 3b may also
25 have a surface that is rugged, i e a surface with a lot of very small grooves or ribs, similar to the small ribs shown in FIG 7 as pattern C' and E' of the patterns C and E, which are smaller than said sub patterns 3", for creating a basic sound when the tip 7 in contact with
30 the sub areas 3b moves over them. This basic sound facilitates the sound recognition by means of a more exact detecting of the position of the tip 7. The centre area 3a should be as smooth as possible in relation to the sub areas 3b for the same reason.

A sequence of movements is shown for clarity reasons in the form of bold lines on the surface 3' for entering a character. The movement starts in the centre area 3a at point s, the sub pattern A is then passed by the tip 7 and defines from which group the desired character, e g the small letter f, is going to be chosen. Then the tip 7 is moved from the first sub area, after passing the sub pattern A, into the second sub area, and past the second sub pattern H back into the centre area 3a at position e. The second sub pattern H defines the position of the small letter f in the chosen group, i e in the second position in the upper row in the first sub area 3b. Another character is entered by moving the tip 7 in a different sequence, e g the lower-case character x is entered by moving the tip 7 from the centre area 3a at point s', past sub pattern A into the sub area in the upper right hand corner of surface 3', and into a second sub area followed by a third sub area 3b located in the lower right hand corner of surface 3', and back into the centre area 3a at point e' past sub pattern C.

Another sequence of movements is shown in FIG 4 in the form of bold lines on the surface 3' for entering another character. The first movement from position s" in the centre area 3a past sub pattern H into the first sub area defines a change of character group. The movement from this first sub area, past the sub pattern H once more, back into the centre area 3a at position e", defines a change from lower-case letters to capital letters, and wherein the symbol in the middle of the three symbols above sub pattern H is activated. The subsequent "second start" movement from the sub area 3a at position s^, past sub pattern G and into sub area 3b, defines from which character group the character is going to be chosen. The movement from this sub area back

into the centre area 3a at position e^{\wedge} , past the sub pattern G once more, defines the middle position in the upper row for letter A. If the character number 4 is going to be entered after capital A above, the tip 7 is moved from point s^* in the centre area 3a, past sub pattern D into the lower middle sub area, this defines a change of character group. The movement from this first sub area past the next adjacent sub area at the lower right-hand corner and into the right-hand middle sub area, past sub pattern C back into the centre area 3a at point e^* , defines the position of the number 4, i e two steps from the middle square symbol in the first chosen character group in the lower sub area.

FIG 5 shows a preferred embodiment of a pattern 3" with eight sub patterns A, B, C, D, E, F, G, H with different combinations of ribs, wherein each sub pattern can be combined with any sub area 3b. The illustration in section is done with reference to only one sub pattern F along line x-x in FIG 3 and 4. Other designs of the pattern instead of ribs can be used, such as grooves or any other form, as shown in FIG 6. The ribs can also be round, flat or have any other design, as shown in an enlarged scale in FIG 8. The ribs can also have different sizes, creating sounds with higher frequencies, as shown by sub pattern C' and E' in FIG 7. The different sub patterns in FIG 5 will be explained in the form of combinations of straight arrows (\uparrow) pointing upwards. Sub pattern A consists of one rib (\uparrow), whereas sub pattern B consists of two ribs ($\uparrow\uparrow$) with a mutual distance d. Sub pattern C has three ribs, wherein a pair of ribs have a mutual distance d and the third rib is arranged a distance more than 2d from the first pair ($\uparrow\uparrow\uparrow$). Sub pattern D also includes three ribs, where one rib is placed adjacent the centre area 3a and the other two ribs are placed a distance more than 2d from the

first rib ($\uparrow \uparrow$). Sub pattern E comprises four ribs with two pair of ribs with a mutual distance d placed a distance more than $2d$ from each other ($\uparrow \uparrow \uparrow$). Sub pattern F consists of three ribs with a mutual distance d ($\uparrow \uparrow \uparrow$). Sub pattern G has four ribs with a mutual distance d ($\uparrow \uparrow \uparrow$), and sub pattern H consists of two ribs with a mutual distance more than $2d$ from each other ($\uparrow \uparrow$).

FIG 6 shows a preferred embodiment of a pattern 3" with eight sub patterns A, B, C, D, E, F, G, H with different combinations of grooves instead of ribs as in FIG 5. The illustration in section is done with reference to only one sub pattern F along line x-x in FIG 3 and 4. The mutual distances between the grooves are the same as in FIG 5. The grooves can have any other design and size, such as a more shallow and/or wider form, or have a more rounded bottom.

FIG 7 shows another preferred embodiment of a pattern 3" with eight sub patterns A, B, C, D, E, F, G, H with different combinations of ribs as in FIG 5. The illustration in section is done with reference to only one sub pattern F along line x-x in FIG 3 and 4. Distances and sizes of the ribs are the same as all the patterns 3" in FIG 5 except for sub pattern E and C. Sub pattern C has three ribs, wherein a pair of ribs have a mutual distance d and a third rib is arranged a distance more than $2d$ from the first pair. The area between the single rib and the pair of ribs is equipped with several small ribs similar to the basic pattern in the sub areas 3b for creating a kind of basic sound ($\uparrow \uparrow \uparrow$). Sub pattern E comprises two bigger ribs with a mutual distance d placed a distance more than $2d$ from each other. The area between the pair of ribs has several small ribs creating a pattern similar to the basic pattern in the sub areas 3b ($\uparrow \uparrow \uparrow$).

FIG 8 shows yet another preferred embodiment of a sub pattern 3" with eight sub patterns A, B, C, D, E, F, G, H as in FIG 5, 6 and 7. The sub patterns will be explained with the help of the same arrows (\uparrow) as in the above description of FIG 5. The sub patterns are illustrated as arrows (\uparrow) in FIG 8 for simplicity reasons. The sub patterns are shown with reference to only one sub pattern F along line x-x in FIG 3 and 4. Sub pattern A has three ribs with a mutual distance of more than $2d$ from each other ($\uparrow \uparrow \uparrow$). Sub pattern B has four ribs consisting of a pair of ribs with a mutual distance d and two other ribs with a distance of more than $2d$ from each other and the first pair ($\uparrow\uparrow \uparrow \uparrow$). Sub pattern C includes three pair of ribs, i e a total of six ribs, with mutual distance of more than $2d$ between each pair, wherein the arrows in each pair have a mutual distance d ($\uparrow\uparrow \uparrow\uparrow \uparrow\uparrow$). Sub pattern D has five ribs ($\uparrow\uparrow \uparrow\uparrow \uparrow$). Sub pattern E includes four ribs with a mutual distance of more than $2d$ ($\uparrow \uparrow \uparrow \uparrow$). Sub pattern F has five ribs but in another combination with one rib placed a distance more than $2d$ from the other four ribs with a mutual distance d ($\uparrow \uparrow\uparrow\uparrow$). Sub pattern G consists of five ribs in a combination similar to F ($\uparrow\uparrow\uparrow\uparrow \uparrow$). Sub pattern H has six ribs with a first pair of ribs with a mutual distance d placed a distance more than $2d$ from the other four ribs with a mutual distance d ($\uparrow\uparrow \uparrow\uparrow\uparrow\uparrow$). FIG 8 also shows six enlargements disclosing different designs and combinations of ribs or grooves that may be used.

In the preferred embodiment of the cover 3, shown in FIG 2, the cover 3 is used for entering a handwritten message, moving a cursor on the display 4 or executing commands for controlling the device 1. This can be accomplished by the following steps shown in FIG 9.

The first step 910 involves opening of the cover 3 followed by a registration in step 920 of whether the telephone mode is to be used alone, step 925, or in combination with sound recognition in step 930. If sound
5 recognition of handwriting on the cover 3 is going to be used, then one tap with the pen 7 in the middle of the cover 3 or pressing of a key on the keypad 6 has to be done to initiate the sound recognition function. In the next step the tip 7 is moved on the surface 3' of the
10 cover 3, thereby creating a sound that is detected in step 930 by means of a microphone 5, converted into electric form in a step 940, forwarded to the processing device in a step 950, and recognised with suitable software in a step 960. The recognised information is
15 then converted into digital data by means of the processing device, shown in a step 970, and recognised as text or commands in a step 980. If the digital data is intended for moving a cursor or entering text, it is forwarded to the display 4 as in step 985, or,
20 alternatively, if the digital data is a command, it is executed for controlling a specific function in the communication device 1 in the last step 990. Functionality like a mouse can be achieved by combining the sound with one or more keys on the keypad 6.

25 The present invention has been described above with reference to a few embodiments, but this description is not intended to be a limitation of the invention. Embodiments other than the ones explicitly disclosed are equally possible within the scope of the
30 invention, as defined by the appended independent claims.

CLAIMS

1. A portable communication device (1) having a microphone (5) and an processing device for receiving a handwritten message from a user and converting the message into digital data, **characterized in that** the processing device is operatively connected to the microphone (5), so that different sounds caused by movement over different patterns and/or textures on a surface (3') of the communication device (1) when the user is hand-writing on said surface (3') may be acoustically detected by the microphone (5) and forwarded, in electric form, to the processing device.

2. A device according to claim 1, wherein the movement of e g a pen (7) or stylus over different combinations of said patterns and/or textures on the surface (3') corresponds to different text inputs or commands.

3. A device according to claim 2, wherein the surface (3') is divided into several sub areas and specific sub patterns (3'') for creating specific sounds when e g the pen (7) or the stylus in contact with the surface (3') moves against these sub patterns (3'').

4. A device according to claim 3, wherein the surface (3') consists of at least one centre area (3a) surrounded by at least one outer sub area (3b) with adherent sub pattern (3'').

5. A device according to claim 4, wherein the surface (3') consists of one centre area (3a) surrounded by at least two, preferably eight, sub areas (3b), whereby each sub area (3b) has an adherent sub pattern (3'') arranged between the centre area (3a) and respective sub area (3b).

6. A device according to claim 5, wherein the surface (3') has multiple sets of character groups, preferably more than two sets, for each sub area (3b) comprising different combinations of small and capital letters, figures, punctuation marks, or any other characters that are needed for writing a message.

7. A device according to claim 6, wherein the surface (3') comprises more than one combination of sub patterns (3"), preferably one combination for each sub area (3b), each of the sub patterns consisting of ribs or grooves of different sizes, preferably ribs, which are arranged in different numbers and with different mutual distances creating a specific pattern, that causes a specific sound for each sub pattern when being passed by e g a tip of a pen (7) or any other stylus.

8. A device according to claim 7, wherein the surface (3') is placed on a cover (3) of the communication device (1), or on any other separate substantially planar surface of an external accessory, which is operatively connected to the processing device of the communication device (1), such as a separate pad, a table surface, or a portable device for entering text or commands.

9. A device according to any preceding claim, wherein the processing device comprises: at least one of a central processing unit (CPU), a digital signal processor (DSP) or a programmable logic array (PLA); together with a memory, such as an electrically erasable programmable read-only memory (EEPROM), a flash memory or similar means; and a set of program instructions stored in the memory and executable by the controller.

10. A device according to any preceding claim,
wherein the communication device (1) is a portable
device for entering text or commands into it, preferably
5 a mobile or cellular telephone.

11. A method of detecting, recognising, converting
and entering data into a communication device (1) such
as a mobile phone, **characterized by the steps of**
10 detecting (930) different sounds, caused by
movement over different patterns and/or textures on a
surface (3') of the communication device (1) when the
user is hand-writing on said surface (3'), with a
microphone (5),
15 converting (940) the sound into electric form by
means of the microphone (5),
forwarding (950) the sound, in electric form, to
an processing device of the communication device (1),
executing (960), in the processing device, a
20 software routine for recognising the sound,
converting (970), in the processing device, the
recognised sound into digital data, and
forwarding (985) the digital data to a display (4)
of the communication device (1), or using the sound, in
25 the form of digital data, for executing commands (990)
that control desired functions in the communication
device (1).

A	US 5625354 A (LERMAN), 29 April 1997 (29.04.97), column 1, line 44 - column 2, line 52 --	1-11

 Further documents are listed in the continuation of Box C. See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search

22 February 2001

Date of mailing of the international search report

20 03-2001

Name and mailing address of the ISA/

Swedish Patent Office

Box 5055, S-102 42 STOCKHOLM

Facsimile No. +46 8 666 02 86
