(54) Title: REJECTION OF FALSE TURNS OF ROTARY INPUTS FOR ELECTRONIC DEVICES

FIG. 2

(57) Abstract: Various embodiments for detecting and rejecting false, unintended rotations of rotary inputs of electronic devices are disclosed herein. In one example, an electronic device is provided with an optical detector that measures the distance between the electronic device and the wearer's forearm or hand, and when the distance is smaller than a threshold distance, the turns of the rotary input are false, unintended turns. In another example, a crown of a rotary input includes a plurality of capacitive sensors that detects the presence of a wearer's finger, which when absent, the turns of the rotary input are false turns. In another example, deflections or positions of a shaft of the rotary input are measured and if the deflections/positions indicate an upward force on the rotary input (which are likely caused by the wearer's forearm or hand), the turns of the rotary input are false turns. Other embodiments are described herein.

REJECTION OF FALSE TURNS OF ROTARY INPUTS FOR ELECTRONIC DEVICES

Technical Field

5 **[0001]** The present disclosure relates generally to rotary input devices for electronic devices, and more particularly relates to rotary input devices for wearable electronic devices.

Background

10 **[0002]** Electronic devices – such as wearable computing devices (e.g., watches), mobile devices, mobile phones, tablet computers, music and multi-media players, gaming devices, and other handheld, wearable or portable devices – have one or more inputs such as buttons, touch screens, switches, and rotary inputs that can perform various functions.

15 **[0003]** With some rotary inputs or rotary controls, the present inventors have recognized that there may be false inputs that are not intended by the user but occur when the rotary inputs are inadvertently or unintentionally moved by contact with clothing, portions of a user's arm or hand or other items.

20 **[0004]** For instance, as shown in Figs. 1A-1B, with a wearable electronic device 20 in the form of a watch, rotary input(s) may be in the form of a crown 22 that rotates to provide input to and control of the wearable electronic device 20. Since this crown 22 is a user input, external to the device, it is possible during normal wear that the crown 22 will be turned without the user intending it be turned -- for example, when a user puts their hand in their pocket or rotates their wrist into extension (Fig. 1A), hitting the crown 22 into their lower forearm 24 or the back of their hand 26 (Fig. 1A).
25 Figure 1C shows an electronic device 20 positioned on a user's body (represented by dashed lines 24, 26) that could be the user's arm or back of the user's hand. If such a rotary input 22 also wakes the electronic device 20 from a sleep mode and turns on the screen, these false turns may not only be distracting to the user, they may also waste battery charge of device 20 that could have been saved for intended
30 interactions.

[0005] Rotational motion of the user's hand or arm – such as shown in Fig. 1B or when for instance the user is opening a door, unscrewing a jar lid, or the like – may also result in inadvertent, unintentional false turns of the crown 22 of the wearable electronic device 20.

- 5 [0006] Accordingly, as recognized by the present inventors, what is needed are mechanisms and processes for detecting and rejecting false, unintended rotations of rotary inputs of electronic devices.

Summary

- 10 [0007] According to one broad aspect of one embodiment of the present disclosure, disclosed herein is an electronic device configured to differentiate between false turns of a rotary input device unintended by a user, and valid turns of the rotary input device intended by the user. In one example, an electronic device may include a processor; a rotary input coupled with the processor, the rotary input having a shaft connected with a crown, the rotary input providing rotary input turn data to the
15 processor when the rotary input is rotated; and a module operating on the electronic device, the module determining whether the rotary input turn data from the rotary input is invalid data resulting from unintended rotations of the rotary input.

- [0008] In one example, the module determines whether an amount of rotations of the rotary input is greater than a threshold amount of rotations, and if not, the input turn
20 data is considered invalid data. In another example, the module determines whether a rate of rotations of the rotary input is greater than a threshold rate of rotations, and if not, the input turn data is considered invalid data.

- [0009] In another example, the electronic device may include a shield extending from the housing, the shield positioned around a bottom portion of the crown. The shield
25 can reduce inadvertent contact between the user's body (such as the user's arm or back of the hand) with the crown of the rotary input.

- [0010] In another example, the electronic device may include the shaft being positioned on the housing along an axis that is positioned above a centerline of the housing. In this manner, inadvertent contact between the user's body (such as the
30 user's arm or back of the hand) with the crown of the rotary input is reduced when

compared with an electronic device having the shaft of the rotary device positioned at or below the centerline of the housing.

[0011] In another example, the electronic device may include a light source positioned within the housing, the light source emitting light in a direction toward a portion of the user's body; and a detector positioned within the housing, the detector detecting one or more reflections of the light from the portion of the user's body. In this example, the module determines whether the portion of the user's body is in contact with the crown, and if so, the input turn data may be considered invalid data.

[0012] In another embodiment, the electronic device may include one or more capacitive sensors positioned on the crown, the sensors configured to detect contact with a user's finger. In this example, the module determines whether the rotation of the rotary input resulted from contact between the user's finger and the crown, and if not, the input turn data may be considered invalid data.

[0013] In another example, an electronic device may include one or more sensors detecting a position or movement/deflection of the shaft. In this example, based on the shaft deflection the module determines whether the rotation of the rotary input resulted from contact with an upper portion of the crown, and if not, the input turn data may be considered invalid data.

[0014] The electronic device may be in various forms, such as a wearable computing device having a touchscreen coupled with the processor. In one example, if the module determines that the input turn data is valid data from the rotary input, the processor alters the contents of the touch screen bases on the input turn data; and if the turn data is determined to be invalid data resulting from false, unintended turns of the rotary input, the turn data is rejected and the processor does not alter the contents of the touch screen based on the input turn data.

[0015] According to another broad aspect of another embodiment of the present disclosure, disclosed herein is an electronic device having a housing, wherein the electronic device may include a processor; at least one rotary input coupled with the processor, the rotary input providing rotary input turn data to the processor when the rotary input is rotated, the rotary input having a shaft connected with a crown; and at least one module operating on the electronic device, the module determining

whether the rotary input turn data from the rotary input is valid data resulting from a user's rotations of the rotary input.

5 [0016] In one example, the module determines whether an amount of rotations of the rotary input is greater than a threshold amount of rotations, and if so, the input turn data may be considered valid data. In another example, the module determines whether a rate of rotations of the rotary input is greater than a threshold rate of rotations, and if so, the input turn data may be considered valid data.

10 [0017] In another example, the electronic device may include a light source positioned within the housing, the light source emitting light in a direction toward a portion of the user's body; and a detector positioned within the housing, the detector detecting one or more reflections of the light as reflected from the portion of the user's body; wherein the module determines whether the portion of the user's body is in contact with a lower portion of the crown, and if not, the input turn data may be considered valid data.

15 [0018] In another example, the electronic device may include one or more capacitive sensors positioned on the crown, the sensors configured to detect contact with a user's finger; wherein the module determines whether the rotation of the rotary input resulted from contact between the user's finger and the crown, and if so, the input turn data may be considered valid data.

20 [0019] In one example, the electronic device may include one or more sensors detecting a position of the shaft; wherein the module determines whether the rotation of the rotary input resulted from contact with an upper portion of the crown, and if so, the input turn data may be considered valid data.

25 [0020] According to another broad aspect of another embodiment of the present disclosure, disclosed herein is a process for an electronic device having at least one rotary input providing data, the process may include detecting one or more rotations of the rotary input; and determining whether the rotations resulted from inadvertent contact with the rotary input. In one example, if the determining operation determines that the rotations resulted from inadvertent contact with the rotary input,
30 the data from the rotary input may be rejected.

[0021] In another example, the process may include detecting a distance between the electronic device and a portion of a user's body; and comparing the distance to a threshold distance to determine whether the rotations resulted from inadvertent contact with the rotary input.

- 5 [0022] In another example, the process may include detecting a presence or an absence of contact on the rotary input with a user's finger to determine whether the rotations resulted from inadvertent contact with the rotary input.

- [0023] In one example, the process may include detecting a position of a shaft of the rotary input to determine whether the rotations resulted from inadvertent contact with
10 the rotary input.

[0024] Other embodiments of the disclosure are described herein. The features, utilities and advantages of various embodiments of this disclosure will be apparent from the following more particular description of embodiments as illustrated in the accompanying drawings.

15 Brief Description of the Drawings

[0025] Figure 1A illustrates an example of a wearable electronic device positioned on a user's arm which can generate false, inadvertent turns of a crown of a rotary input.

10 turns of the rotary input, in accordance with one embodiment of the present disclosure.

[0033] Figure 6B illustrates a side view of Figure 6A showing an electronic device with a rotary input having one or more capacitive sensors to aid in rejecting false
15 turns of the rotary input, in accordance with one embodiment of the present disclosure.

[0034] Figure 7 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure.

[0035] Figure 8 illustrates an example of a block diagram of an electronic device with
20 a rotary input and a shaft deflection detector to aid in rejecting false turns of the rotary input, in accordance with one embodiment of the present disclosure.

[0036] Figure 9 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure.

25 [0037] Figure 10 illustrates an example of a block diagram of an electronic device with a rotary input and one or more modules to aid in detecting and rejecting false turns of the rotary input, in accordance with one embodiment of the present disclosure.

[0038] Figure 11 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure.

5 [0039] Figure 12 illustrates an example of an electronic device with a rotary input having a mechanical structure to aid in reducing false turns of the rotary input, in accordance with one embodiment of the present disclosure.

[0040] Figure 13 illustrates an example of an electronic device with a rotary input positioned at an offset position to aid in reducing false turns of the rotary input, in accordance with one embodiment of the present disclosure.

10 Detailed Description

[0041] Disclosed herein are various embodiments of mechanisms and processes for detecting and rejecting false, unintended rotations of rotary inputs of electronic devices, such as wearable computing devices. In one example of the present disclosure, an electronic device is provided with an optical detector that measures
15 the distance between the electronic device and a surface of the wearer's forearm or hand, and when the distance is smaller than a baseline or threshold distance, the turns of the rotary input may be considered to be false, unintended turns. In another example of the present disclosure, a crown of a rotary input of an electronic device includes one or more capacitive sensors which detect the presence of a wearer's
20 finger, which when absent, the turns of the rotary input may be considered to be false, unintended turns. In another example, deflections or positions of a shaft of a rotary input of an electronic device are measured and if the deflections/positions indicate an upward force on the rotary input (which are likely caused by the wearer's forearm or hand), the turns of the rotary input may be considered to be false,
25 unintended turns. Other embodiments are described herein.

[0042] Figure 2 illustrates an example of a wearable electronic device 30 having a plurality of rotatable inputs 32, in accordance with one embodiment of the present disclosure. Electronic device 30, in this example in the form of a computing device wearable on a user's wrist, may have one or more rotary inputs 32 which may
30 include a crown or other structure 34 which may be attached to a shaft 35, wherein the crown 34 is configured to be rotated by the user, for instance by one or more of

the user's fingers or thumbs. The electronic device 30 may include a housing 36 that encloses and protects the contents of electronic device 30, a display 38 (such as a touch screen) to display data and information to the user as well as to accept touch input from the user, audio output/speakers 39, and in one example may also include
5 a band or other structure 40 to attach the electronic device 30 to the user, for instance to the user's arm.

[0043] Device 30 may be configured to accommodate both left and right handed use, in which case a user can decide to orient the device 30 and crown 34 pointing either up the user's arm or down the user's arm, as desired.

10 **[0044]** Electronic device 30 may be configured as a portable computing device, and as shown in Figure 3, may include a processor 42, memory 44 (which may include ROM and RAM for program memory and data stores), and communications interfaces 46 (such as but not limited to wireless interfaces, Bluetooth interfaces, USB interfaces, Wi-Fi interfaces, TCP/IP interfaces, network communications
15 interfaces, or any conventional communication interfaces).

[0045] Electronic device 30 may include various input devices 48, such as but not limited to, touch inputs 50 (which may be part of or separate from touchscreen 38), audio/microphone input 52, data from accelerometer(s) 53, and rotary inputs 32 which can be provided to enable a user to manipulate or control electronic device 30,
20 and other inputs such as buttons, switches, sliders or any other conventional input.

[0046] In one example, rotary inputs 32 provide rotary input turn data to the processor 42, and such turn data may include, but is not limited to, a number of turns, or increments of turns, of crown 34, a direction of turns (e.g., clockwise or counterclockwise rotation of crown 34), a rate of turns, a length of time of rotations of
25 crown 34, and other data and parameters as described herein.

[0047] As used herein, the terms "turns" or "rotations" or the like (such as in the phrases "false turns" or "inadvertent turns") include any movements, fractional rotations, partial rotations, full rotations, revolutions or any degree or amount of rotary movement of rotary input 32/crown 34, and these terms are used
30 interchangeably herein.

[0048] Rotary input 32 allow a user to perform a variety of functions, such as but not limited to scroll contents of displays, scroll menus, scroll selections or options, manipulate lists or data, advance or rewind audio or video, move pointers, or perform other various controls of electronic device 30 or the content of display 38.

5 [0049] In accordance with some embodiments of the present disclosure, electronic device 30 may include one or more module(s) 54 for detecting and/or handling false or inadvertent movements or turns of the rotary inputs 32. Module(s) 54 may include one or more of the features, functions or processes disclosed herein. Module(s) 54 may be implemented in various manners, such as but not limited to, as hardware
10 devices, specialized integrated circuits, logic, computer program products, code modules operating on processor 42 or device 30, or in any combination thereof.

[0050] Various embodiments of electronic device 30 are described having one or more module(s) 54 that can determine whether turns of rotary input 32/crown 34 (along with the associated rotary input turn data) are (or possibly are) false
15 inadvertent turns with invalid data that were unintended by the user, or whether turns of rotary input 32/crown 34 (along with the associated rotary input turn data) are (or possibly are) turns with valid data that were intended by the user.

[0051] Figure 4 illustrates an example of an electronic device 30 with a rotary input 32, wherein the electronic device is configured with a light source 60 to emit light 62
20 onto the wearer's body (such as the user's arm 24 or back of the user's hand 26), and a detector 64 that detects reflections of light 62. The light 62 can be emitted prior to and/or during rotation of the rotary input 32. Based on the characteristics of the reflections, electronic device 30 determines whether to reject the rotations of rotary input 32 as false, inadvertent rotations or as valid rotations intended by the
25 user. For instance, the light 62 can be used to determine the distance from the crown to the wearer's arm 24 or back of the wearer's hand 26, and the determined distance can be used as a factor in deciding whether rotations of the crown 34 should be rejected or accepted. In one example, if the detected light reflections indicate that the wearer's arm 24 or hand 26 are outside of a specified distance away
30 from the crown 34, then the rotations of crown 34 can be deemed valid rotations intended by the user; and conversely, if the detected light reflections indicate that the wearer's arm 24 or hand 26 are within a specified distance near the crown 34, then the rotations of crown 34 can be deemed false, inadvertent rotations and rejected.

[0052] In another example, the distance from the crown to the user's arm 24 or hand 26 is used as a factor in deciding whether to accept or reject rotations of the crown 34. For example, when the distance from the crown to the user's arm 24 or hand 26 goes to zero or is within a defined distance, turns of the crown 34 would be rejected unless it is detected that the crown was touched in at least two discrete places, such as a top portion of the crown and a bottom portion of the crown, such as when the user is attempting to rotate the crown while the user's hand is in an extension position.

[0053] In one example, the light source 60 can be a light emitting diode (LED) such as an infrared LED. In one embodiment, the shaft 35 of the rotary input 32 (or portions of the shaft) may be clear or transparent or may include a light pipe, and the light source 60 may be configured so that the light emits out of the shaft 35. In another example, the light source 60 may be positioned to transmit light out of the housing 26 of the electronic device 30, such as through an opening or a window in the housing 36.

[0054] Detector 64 can be an optical detector such as a photodiode that detects reflected light, such as but not limited to infrared light. The housing 36 may be provided with a window, and the detector 64 can be placed within the housing 36 adjacent to the window. For instance, the window may be a dedicated window in the housing 36, or a speaker port or other opening in the housing 36 can also serve as the window where the detector receives reflected light.

[0055] In Figure 5, an example of a process for detecting and rejecting false turns of a rotary input of an electronic device is shown, in accordance with one embodiment of the present disclosure. At operation 70 light is transmitted by the electronic device. In one example, operation 70 transmits infrared light, although other types of light may be transmitted. Operation 72 detects reflections of the transmitted light.

[0056] At operation 74, a distance can be calculated based on the transmitted light of operation 70 and reflected light detected by operation 72. For instance, operation 72 can detect reflections of the transmitted light off of a user's arm or back of the hand depending upon the position of the electronic device relative to the user.

[0057] In one example, operations 70-74 may be performed during an initialization or calibration phase, for instance by prompting the user through the display of the electronic device for the user to place the electronic device on the user's wrist in a normal, flat, non-extended position. This can be used to determine a baseline or default distance value.

[0058] At operation 76, movements or turns of the crown or rotary input are detected, and operation 78 determines a distance, for instance a distance from the electronic device to a wearer's arm or back of the hand that exists while the crown is being rotated. In one example, operation 78 may include transmitting light, detecting reflected light, and calculating a distance based on the reflected light, in a manner similar to operation 70, 72, 74.

[0059] Operation 80 determines whether the distance measured by operation 80 is acceptable or unacceptable. For instance, operation 80 may determine whether the distance measured by operation 78 is below a desired threshold, wherein the threshold may be established by the distance calculated at operation 74. For instance, in one example, a distance of zero or near zero may indicate that the crown is in direct contact with the wearer's back of the hand or forearm. If an acceptable distance is measured by operation 78, then control may be passed to operation 82 where the rotations of the crown/rotary input are accepted as true, intended user input. Conversely, if an unacceptable distance is measured by operation 78, then control may be passed to operation 84 where the rotations of the crown/rotary input may be rejected as false, unintended user input. In another example, operation 84 may indicate that the unacceptable distance be used as a factor in determining whether the turns of the rotary input of the electronic device may be false turns.

[0060] If operations 80-82 determine that the turns of the rotary input are true, intended turns, then operation 86 can process the movements of the rotary inputs as needed so that the electronic device responds appropriately to the user input received through the rotary input (such as but not limited to, changing the contents of the display, providing audible feedback, or otherwise processing the rotary input received from the user).

[0061] In another embodiment of the present disclosure and referring to Figure 6A-6B, an electronic device 30 can be formed having a rotary input 32 having one or more capacitive sensors 90 to aid in detecting and rejecting false turns of rotary input 32. In one example, capacitive sensors 90 are shown in Figure 6B (side view) as
5 four sensors 90A, 90B, 90C and 90D, each positioned about a portion of the crown 34. It is understood that more or fewer sensors 90 could be used, and sensors 90 could be positioned on other portions of crown 34 or positioned in different orientations on crown 34.

[0062] In one example, sensors 90 can be used sense distance to the wearer, for
10 instance distance from the crown to the wearer's wrist or back of the hand, or to sense or detect actual contact therebetween. In another example, sensors 90 can also be used to detect a user's finger placed on top of crown 34, or on a side of crown 34, to actuate the crown. Sensors 90 can also be used to distinguish whether rotation of crown 34 is resulting from detected contact with the top of the crown,
15 which would tend to indicate that the rotation is intended by the user through a finger of the user; or whether rotation is resulting from detected contact with the bottom of the crown 34, which would tend to indicate contact with a wearer's arm or back of their hand which is a false, unintended rotation that may be rejected.

[0063] In one example, electronic device 30 utilizes a rotary encoder (e.g., an
20 absolute position rotary encoder) as part of the rotary input 32, and may also include with capacitive sensors 90 in the crown 34. The rotary encoder may be configured, in one example, to have marked lines, detents or other indicia delineating a portion, fraction, increment or unit of movement when compared with a full rotation of the rotary input 32. In one example, the rotary encoder may have 50 marked lines
25 across a full 360 degree rotation, which can be interpolated upwardly by the processor 42, false turn rejection module 54 or other element within device 30, such as by a factor of four (4X) to create 200 counts per revolution or rotation which equates to approximately 1.8 degrees of resolution. In this manner, processor 54 and/or false turn rejection module 54 can detect a fractional/ partial amount or
30 degree of rotatory movement of the rotary input 32/crown 34 which is less than a full rotation of the rotary input 32/crown 34. It is understood that the amount of resolution of detected rotatory movement of rotary input 32/crown 34 can be larger or

smaller in other embodiments, depending upon the particular implementation, as is the interpolation of such detected movement.

[0064] Electronic device 30 can be configured to dynamically determine, at any given time, which sensors 90 on the crown 34 are towards the upper portion or top surface 92 (Figure 6A) of electronic device 30, and which sensors 90 on the crown are towards the lower portion or bottom surface 94 (Figure 6A) of the electronic device 30. In one example, electronic device 30 could be configured so that rotations of the crown 34 resulting from contact detected by sensors 90 towards the lower portion/bottom 94 of the electronic device 30 may be ignored or rejected as false turns, while rotations of the crown 34 resulting from contact detected by sensors 90 towards the upper portion 92 of electronic device 30 may be accepted as valid input intended by the user. In another example, the lower portion of crown sensors 90 could be dynamically desensitized, while the upper portion of the crown sensors 90 could be dynamically highly sensitized.

[0065] In another example of the present disclosure, sensors 90 on crown 34 can be used to distinguish the touch of a finger versus false turns resulting from a touch of a wrist or back of the user's hand. Sensors 90 on crown 34 may sense the presence of a user's finger by determining a local capacitance maximum value detected; in contrast, the capacitance profile generated by contact of a user's wrist with sensors 90 may appear more like a plane of capacitance and less like a local maximum. In this manner, sensors 90 on crown 34 can be used to distinguish the touch of a finger versus false turns resulting from a touch of a wrist or back of the user's hand.

[0066] Figure 7 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure. At operation 100, the position of the capacitive sensors relative to the electronic device are determined. In one example, the position of the sensors relative to the top (92 in Figure 6A) and/or bottom (94 in Figure 6A) of the device may be determined based on the rotary position of the crown or position of the shaft of the crown, for instance through the use of a rotary encoder.

[0067] At operation 102, movements or turns of the rotary input device are detected. At operation 104, the capacitive sensors on the rotary input device are read, for instance, to determine which of the capacitive sensors detect touch or contact from a

user. At operation 106, a determination is made whether the contact is originating from capacitive sensors positioned towards the bottom (94 in Figure 6A) of the device or towards the top (92 in Figure 6A) of the device. If operation 106 determines that contact is originating from sensors positioned towards the bottom of the device, then operation 108 may reject the turns of the rotary input as false or unintended turns.

[0068] Conversely, if operation 106 determines that contact is originating from sensors positioned toward the top of the device, then operation 110 may accept the turns of the rotary input as true, intended turns by the user. Operation 112 may then process the rotations of the rotary input, and the electronic device may respond accordingly.

[0069] In one example, if sensors towards the top and towards the bottom of the device are simultaneously triggered, this input scenario could mean that the user is contacting the top of the crown with a finger while the bottom of the crown is being contacted by the user's arm or back of the hand. In one example, such scenario could be processed as true user input based on an assumption that the user is intentionally rotating the rotary input in a manner that is overcoming the contact from the user's arm or back of the hand.

[0070] Figure 8 illustrates an example of a block diagram of an electronic device with a rotary input 32 having a crown 34 attached to a shaft 35, wherein a shaft deflection detector 120 is provided to aid in detecting and rejecting false turns of the rotary input 32, in accordance with one embodiment of the present disclosure. In one example, the shaft 35 of the rotary input 32 is positioned or supported by pivot supports or suspension supports 122, which may include one or more O-rings.

[0071] Shaft deflection detector 120, in one example, measures or determines the position of the shaft 35 (such as an internal end of the shaft 35), such as by determining the distance and/or direction that shaft 35 moves or travels during a rotation of rotary input 32. The deflections of shaft 35 are used to determine whether the turns of crown 34 are resulting from downward force for instance from a user's finger or thumb (which would be associated with true, intended rotary input), or resulting from upward force for instance from inadvertent contact between the crown

34 and the user's arm 24 or back of the hand 26 (which would be associated with false, unintended rotary input).

[0072] In another embodiment, detector 120 senses the moment or torque caused by downward pressure of a finger on the crown 34, compared to the negative moment
5 caused by upward pressure of the user's arm 24 or wrist 26 on the crown 34.

[0073] Figure 9 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure.

[0074] At operation 130, the position of the shaft of the rotary input relative to the
10 electronic device is determined. In one example, the position of the shaft relative to the top and/or bottom of the device may be determined for instance through the use of a position sensor or torque sensor configured to monitor the shaft.

[0075] At operation 132, movements or turns of the rotary input device are detected. At operation 134, the deflection or direction of shaft movement is detected. At
15 operation 136, a determination is made whether the rotation of the crown/rotary input is originating from generally upward contact with the crown, or originating from generally downward contact with the crown. If operation 136 determines that the rotation of the crown/rotary input is originating from generally upward contact with the crown – for instance from inadvertent contact between the crown 34 and the
20 user's arm 24 or back of the hand 26 which would be associated with false, unintended rotary input – then operation 138 may reject the turns of the rotary input as false or unintended turns.

[0076] Conversely, if operation 136 determines that the rotation of the crown/rotary input is originating from generally downward contact with the crown – for instance
25 from contact from a user's finger or thumb into the crown which would be associated with true, intended rotary input – then operation 140 may accept the turns of the rotary input as true, intended turns by the user. Operation 142 may then process the rotations of the rotary input, and the electronic device may respond accordingly.

[0077] Figure 10 illustrates an example an electronic device 30 with a rotary input 32
30 and one or more modules (for instance, modules 54 in Figure 3) that aid in detecting

and rejecting false turns of the rotary input 32, in accordance with one embodiment of the present disclosure.

[0078] In one example, modules 54 perform one or more functions or operations described herein. Modules 54 may also differentiate between true, intended turns of rotary input 32 and false, unintended turns of rotary input 32 by analyzing characteristics of the rotations detected by electronic device 30 when rotary input 32 moves. For instance, false turns would be expected to be relatively short duration, low torque events since they are often due to friction. These events could be rejected using a torque sensor measuring torque about the shaft axis, or a rotary detector or rotatory encoder in communications with the shaft 35 measuring characteristics of shaft rotations.

[0079] In one example, one or more thresholds (such as a minimum number of rotations, a minimum rate of rotations, a minimum amount of time during rotations, a minimum amount of rotational torque, or any combination thereof) may be defined and stored in device 30, wherein the characteristics of the detected rotations of rotary input 32 need to exceed the threshold before electronic device 30 accepts the rotations as valid, intended input from the user.

[0080] In one example, the electronic device 30, when in a sleep mode (for instance, with the display 38 off) and upon detecting rotation of rotary input 32, may determine whether the characteristics of the rotations exceed the threshold(s), and if not, the detected turns may be deemed false, unintended turns and the device 30 is maintained in the sleep mode (with the display 38 off), thereby conserving stored battery energy.

[0081] Conversely, if the device 30 determines the characteristics of the rotations exceed the threshold(s), the detected turns may be deemed true, intended turns and the device 30 awakes out of the sleep mode and the display 38 may be activated.

[0082] For instance as an example for illustrative purposes only, approximately 160 to 180 degrees of turn of the crown 34 of input 32 may be a minimum threshold to register or trigger waking up the electronic device 30 out of a sleep mode or to perform other functions of the electronic device 30.

[0083] In another example, once the device 30 is awake, the threshold(s) for accepting rotations of the rotary input could be reduced so as to accept lower torques or other lower rotary input characteristics as valid, intended rotary input.

[0084] Figure 11 illustrates an example of a process for detecting and rejecting false turns of a rotary input of an electronic device, in accordance with one embodiment of the present disclosure. At operation 150, the electronic device is in a sleep mode, for instance in a low-power mode with the display off and with one or more of other components of the electronic device in a low-power or sleep mode. At operation 152, movements or turns of the rotary input/crown are detected. At operation 154, characteristics of the rotation or movement of the rotary input are measured or determined. In one example, these characteristics may include but are not limited to the number of rotations, the rate of rotations, the amount of time during rotations, the amount of rotational torque, or any combination thereof.

[0085] At operation 156, a determination is made as to whether the characteristics of the detected rotations, as measured by operation 154, meet or exceed one or more rotation characteristic thresholds. These thresholds may include but are not limited to a minimum number of rotations, a minimum rate of rotations, a minimum amount of time during rotations, a minimum amount of rotational torque, or any combination thereof. If operation 156 determines that the detected rotations of the rotary input did not meet or exceed the rotation characteristic thresholds, then control is passed to operation 158 wherein the detected rotations/turns of the rotary input/crown may be rejected as false, unintended turns; and control may be returned to operation 150 wherein the electronic device is maintained in a sleep mode.

[0086] If operation 156 determines that the detected rotations of the rotary input do meet or exceed the rotation characteristic thresholds, then control is passed to operation 160 wherein the detected rotations/turns of the rotary input/crown may be accepted as true, intended turns and valid user input; and control may be passed to operation 162 wherein the electronic device may be awoken out of the sleep mode, and the display and other functional components of the device may be started up into a normal, operating mode. At operation 164, the movements of the rotary input/crown, for instance as detected by operation 152, are processed accordingly and the electronic device responds to such rotary input by performing one or more functions or operations programmed on the electronic device.

[0087] In another example of electronic device 30, a photoplethysmograph (PPG) sensor may be provided within device 30 to measures the relative blood flow through the user's body proximate the location of the electronic device (such as but not limited to the user's arm/wrist), and to detect, for instance, a wrist clench
5 characteristic or a wrist extension condition. When a wrist clench or extension condition (such as shown in Figure 1A) is detected via the PPG sensor data, these conditions may be considered by the electronic device 30 when determining whether detected rotations of the rotary input 32 are false/unintended turns or true/intended turns.

10 [0088] Figure 12 illustrates another example of an electronic device 30 with a rotary input 32 having a mechanical structure such as a shield 170 extending from the housing 36, wherein the shield 170 surrounds a portion of the crown 34. Shield 170 aids in reducing occurrences of false turns of the rotary input 32, by shielding or partially shielding crown 34 from physical contact with a user's arm 24 or back of
15 hand 26 or other body parts. For instance, shield 170 can reduce the occurrence of false, inadvertent turns of rotary input 32/crown 34 during wrist extensions or other movement (such as movements shown in Figures 1A, 1B). Shield 170 may be configured to cover the bottom of the crown 34, the sides of crown 34, or both.

[0089] Figure 13 illustrates an example of an electronic device 30 with a rotary input
20 32 positioned at upwardly offset position to aid in reducing occurrences of false turns of the rotary input 32/crown 34, in accordance with one embodiment of the present disclosure. In this example, the crown 34 is positioned or centered about an axis 180 that is above the centerline 182 of the housing 36 of device 30. The upwardly offset position of rotary input 32 increases the amount of space between the bottom
25 of the crown 34 and the user's back of the hand or lower forearm. In this manner, occurrences of false turns of crown 34 are decreased when compared with when the crown 34 is positioned or centered at or below the centerline 182 of the housing 36 of device 30.

[0090] In another example of electronic device 30, electronic device 30 can be
30 configured so that if on touch screen 38, two fingers are detected as contacting display 38, then rotational input to the crown 34 may be considered false input.

[0091] In another example of electronic device 30, electronic device 30 may be configured so that when accelerometer 53 senses that the device 30 is moving with general rotational motion or with randomized motion (such as during exercise by the user), device 30 may require a larger amount of rotations of rotary input 32/crown 34
5 or a longer time duration of crown rotations, in order to accept the rotations/input as valid, intended input or to wake up device 30 if device 30 is in a sleep mode.

[0092] Hence, it can be seen that various embodiments of the present disclosure provide an electronic device 30 that detect and/or handle false or inadvertent movements or turns of the rotary inputs 32 which are unintended by the user. An
10 electronic device 30 can be formed utilizing one or more of the features, functions, processes or structures disclosed herein.

[0093] While the methods disclosed herein have been described and shown with reference to particular operations performed in a particular order, it will be understood that these operations may be combined, sub-divided, or re-ordered to
15 form equivalent methods without departing from the teachings of the present disclosure. Accordingly, unless specifically indicated herein, the order and grouping of the operations is not a limitation of the present disclosure.

[0094] It is understood that the directional references provided herein, such as top, bottom, upwards, downwards, clockwise, counterclockwise, left, right, and the like,
20 are provided to describe examples of the embodiments disclosed herein, and are not intended to be limiting.

[0095] It should be appreciated that in the foregoing description of exemplary embodiments of the disclosure, various features of the disclosure are sometimes grouped together in a single embodiment, Figure, or description thereof for the
25 purpose of streamlining the disclosure and aiding in the understanding of one or more of the various aspects. This method of disclosure, however, is not to be interpreted as reflecting an intention that the claims require more features than are expressly recited in each claim. Rather, inventive aspects lie in less than all features of a single foregoing disclosed embodiment, and each embodiment described herein
30 may contain more than one inventive feature.

[0096] While the disclosure is presented and described with reference to embodiments thereof, it will be understood by those skilled in the art that various other changes in the form and details may be made without departing from the spirit and scope of the disclosure.

CLAIMS

We claim:

1. An electronic device having a housing, comprising:
a processor;
at least one rotary input coupled with the processor, the rotary input providing rotary input turn data to the processor when the rotary input is rotated, the rotary
5 input having a shaft connected with a crown; and
at least one module operating on the electronic device, the module determining whether the rotary input turn data from the rotary input is invalid data resulting from unintended rotations of the rotary input.
2. The electronic device of claim 1, wherein module determines whether an amount of rotations of the rotary input is greater than a threshold amount of rotations, and if not, the input turn data is invalid data.
3. The electronic device of claim 1, wherein module determines whether a rate of rotations of the rotary input is greater than a threshold rate of rotations, and if not, the input turn data is invalid data.
4. The electronic device of claim 1, further comprising:
a shield extending from the housing, the shield positioned around a bottom portion of the crown.
5. The electronic device of claim 1, wherein the shaft is positioned on the housing along an axis that is positioned above a centerline of the housing.
6. The electronic device of claim 1, further comprising:
a light source positioned within the housing, the light source emitting light in a direction toward a portion of the user's body; and
a detector positioned within the housing, the detector detecting one or more
5 reflections of the light from the portion of the user's body.
7. The electronic device of claim 6, wherein the module determines whether the portion of the user's body is in contact with the crown, and if so, the input turn data is invalid data.
8. The electronic device of claim 1, further comprising:

one or more capacitive sensors positioned on the crown, the sensors configured to detect contact with a user's finger.

9. The electronic device of claim 8, wherein the module determines whether the rotation of the rotary input resulted from contact between the user's finger and the crown, and if not, the input turn data is invalid data.

10. The electronic device of claim 1, further comprising:
one or more sensors detecting a position of the shaft.

11. The electronic device of claim 10, wherein the module determines whether the rotation of the rotary input resulted from contact with an upper portion of the crown, and if not, the input turn data is invalid data.

12. The electronic device of claim 1, wherein the electronic device includes a touchscreen coupled with the processor.

13. The electronic device of claim 12, wherein when the module determines that the input turn data is valid data from the rotary input, the processor alters the contents of the touch screen in response to the input turn data.

14. The electronic device of claim 12, wherein when the module determines that the input turn data is invalid data, the processor does not alter the contents of the touch screen in response to the input turn data.

15. An electronic device having a housing, comprising:
a processor;
at least one rotary input coupled with the processor, the rotary input providing rotary input turn data to the processor when the rotary input is rotated, the rotary
5 input having a shaft connected with a crown; and
at least one module operating on the electronic device, the module determining whether the rotary input turn data from the rotary input is valid data resulting from a user's rotations of the rotary input.

16. The electronic device of claim 15, wherein module determines whether an amount of rotations of the rotary input is greater than a threshold amount of rotations, and if so, the input turn data is valid data.

17. The electronic device of claim 15, wherein module determines whether a rate of rotations of the rotary input is greater than a threshold rate of rotations, and if so, the input turn data is valid data.

18. The electronic device of claim 15, further comprising:
a light source positioned within the housing, the light source emitting light in a direction toward a portion of the user's body; and

a detector positioned within the housing, the detector detecting one or more
5 reflections of the light from the portion of the user's body;

wherein the module determines whether the portion of the user's body is in contact with the crown, and if not, the input turn data is valid data.

19. The electronic device of claim 15, further comprising:
one or more capacitive sensors positioned on the crown, the sensors
configured to detect contact with a user's finger;

wherein the module determines whether the rotation of the rotary input
5 resulted from contact between the user's finger and the crown, and if so, the input turn data is valid data.

20. The electronic device of claim 15, further comprising:
one or more sensors detecting a position of the shaft;
wherein the module determines whether the rotation of the rotary input
resulted from contact with an upper portion of the crown, and if so, the input turn

5 data is valid data.

21. A process for an electronic device having at least one rotary input providing data, the process comprising:

detecting one or more fractional rotations of the rotary input; and

determining whether the fractional rotations resulted from inadvertent contact
5 with the rotary input.

22. The process of claim 21, further comprising:

if the determining operation determines that the fractional rotations resulted from inadvertent contact with the rotary input, rejecting the data from the rotary input.

23. The process of claim 21, wherein the determining operation further comprises:

detecting a distance between the electronic device and a portion of a user's body; and

- 5 comparing the distance to a threshold distance to determine whether the fractional rotations resulted from inadvertent contact with the rotary input.

24. The process of claim 21, wherein the determining operation further comprises:

- 5 detecting a presence or an absence of contact on the rotary input with a user's finger to determine whether the fractional rotations resulted from inadvertent contact with the rotary input.

25. The process of claim 21, wherein the determining operation further comprises:

- detecting a position of a shaft of the rotary input to determine whether the fractional rotations resulted from inadvertent contact with the rotary input.
