2-f2,4,5-Substituted-anilino)pyrimidine Compounds

The present invention relates to certain 2-(2,4,5-substituted-anilino)pyrimidine compounds and pharmaceutically salts thereof which may be useful in the treatment or prevention of a disease or medical condition mediated through certain mutated forms of epidermal growth factor receptor (for example the L858R activating mutant, the ExonI9 deletion activating mutant and the T790M resistance mutant). Such compounds and salts thereof may be useful in the treatment or prevention of a number of different cancers. The invention also relates to pharmaceutical compositions comprising said compounds and salts thereof, especially useful polymorphic forms of these compounds and salts, intermediates useful in the manufacture of said compounds and to methods of treatment of diseases mediated by various different forms of EGFR using said compounds and salts thereof.

EGFR is a transmembrane protein tyrosine kinase member of the erbB receptor family. Upon binding of a growth factor ligand such as epidermal growth factor (EGF), the receptor can homo-dimerise with another EGFR molecule or hetero-dimerise with another family member such as erbB2 (HER2), erbB3 (HER3), or erbB4 (HER4).

Homo- and/or hetero-dimerisation of erbB receptors results in the phosphorylation of key tyrosine residues in the intracellular domain and leads to the stimulation of numerous intracellular signal transduction pathways involved in cell proliferation and survival. Deregulation of erbB family signalling promotes proliferation, invasion, metastasis, angiogenesis, and tumour cell survival and has been described in many human cancers, including those of the lung, head and neck and breast.

The erbB family therefore represents a rational target for anticancer drug development and a number of agents targeting EGFR or erbB2 are now clinically available, including gefitinib (IRESSA™), erlotinib (TARCEVA™) and lapatinib (TYKERB™, TYVERB™). Detailed reviews of erbB receptor signalling and its involvement in tumourigenesis are provided in New England Journal of Medicine (2008) Vol. 358,1 160-74 and Biochemical and Biophysical Research Communications (2004) Vol. 319, 1-1.1

most common EGFR activating mutations, L858R and delE746_A750, result in an increase in affinity for small molecule tyrosine kinase inhibitors such as gefitinib and erlotinib and a decrease in affinity for adenosine triphosphate (ATP) relative to wild type (WT) EGFR. Ultimately, acquired resistance to therapy with gefitinib or erlotinib arises, for example by mutation of the gatekeeper residue T790M, which is reportedly detected in 50% of clinically resistant patients. This mutation is not believed to hinder the binding of gefitinib or erlotinib to EGFR sterically, merely to alter the affinity to ATP to levels comparable to WT EGFR.

In view of the importance of this mutation in resistance to existing therapies targeting EGFR, we believe that agents which can inhibit EGFR harbouring the gatekeeper mutation may be especially useful in the treatment of cancer.

There remains a need for compounds that may exhibit favourable potency profiles against WT EGFR versus activating mutant forms of EGFR (for example the L858R EGFR mutant, or the delE746_A750 mutant or the Exon19 deletion EGFR mutant) and/or resistant mutant forms of EGFR (for example T790M EGFR mutant), and/or selectivity over other enzyme receptors which may make the compounds especially promising for development as therapeutic agents. In this regard, there remains a need for compounds that show a higher inhibition of certain activating or resistance mutant forms of EGFR while at the same time showing relatively low inhibition of WT EGFR. Such compounds may be expected to be more suitable as therapeutic agents, particularly for the treatment of cancer, due to reduction of toxicology associated with WT EGFR inhibition. Such toxicologies are known to manifest themselves in man as skin rashes and/or diarrhoea. The applicants have surprisingly found that one or more 2-(2,4,5-substituted-anilino)pyrimidine compounds have high potency against several mutant forms of EGFR, while at the same showing relatively low inhibition of WT EGFR.

The compound(s) of the invention may also exhibit advantageous physical properties (for example, higher aqueous solubility, higher permeability, and/or lower plasma protein binding) and/or favourable toxicity profiles (for example a decreased hERG blocking liability) and/or favourable metabolic profiles in comparison with other known EGFR / EGFR-mutant inhibitors. Therefore, such compound(s) may be especially useful in the treatment of disease states in which EGFR and/or activating mutations of EGFR and/or resistance mutations of EGFR are implicated, for example in the treatment of cancer.

In the formulation of drug compositions, it is important for the drug substance to be in a form in which it can be conveniently handled and processed. This is of importance, not only from the point of view of obtaining a commercially viable manufacturing process, but also from the point of view of subsequent manufacture of pharmaceutical formulations (e.g. oral dosage forms such as tablets) comprising the active compound.

The different physical properties of the crystalline forms with respect to each other and with respect to the non-crystalline state may influence markedly the chemical and pharmaceutical processing of a compound, particularly when the compound is prepared or used on an industrial scale.

Further, in the manufacture of oral drug compositions, it is important that a reliable and reproducible plasma concentration profile of drug is provided following administration to a patient. Inter-patient variability in the absorption profile of a drug within the stomach, intestine or bloodstream can have an effect on drug safety and efficacy.

Chemical stability, solid state stability and "shelf life" of the active ingredients are also very important factors. The drug substance, and compositions containing it, should be capable of being effectively stored over appreciable periods of time, without exhibiting a significant change in the active component's physico-chemical characteristics (e.g. its chemical composition, density, hygroscopicity and solubility).
Moreover, it is also important to be able to provide drug in a form which is as chemically pure as possible.

Amorphous materials may present problems in this regard. For example, such materials are typically difficult to handle and to formulate, provide for unreliable solubility, and are often found to be unstable and chemically impure.

The skilled person will appreciate that, if a drug can be readily obtained in a stable crystalline form, the above problems may be solved.

Thus, in the manufacture of commercially viable, and pharmaceutically acceptable, drug compositions, it is important, wherever possible, to provide drug in a crystalline, and stable, form.

It is to be noted, however, that this goal is not always achievable. Indeed, typically, it is not possible to predict, from molecular structure alone, what the crystallisation behaviour of a compound, either as such or in the form of a salt, will be. This can only be determined empirically.

In a further aspect of the invention, certain compounds and salts thereof may be prepared in crystalline forms. These crystalline forms may be characterised as being a particular polymorphic form. When it is stated that the present invention relates to a crystalline form, the degree of crystallinity is conveniently greater than about 60%, more conveniently greater than about 80%, preferably greater than about 90% and more preferably greater than about 95%. Most preferably the degree of crystallinity is greater than about 98%.

The specific solid forms described herein provide X-ray powder diffraction patterns substantially the same as the X-ray powder diffraction patterns shown in the Figures and have the various 2-theta values as shown in the Tables included herein. It will be understood that the 2-theta values of a X-ray powder diffraction pattern may vary slightly from one machine to another or from one sample to another, and so the values quoted are not to be construed as absolute.

It is known that an X-ray powder diffraction pattern may be obtained which has one or more measurement errors depending on measurement conditions (such as equipment or machine used). In particular, it is generally known that intensities in an X-ray powder diffraction pattern may fluctuate depending on measurement conditions. Therefore it
should be understood that the solid forms of the present invention are not limited to the crystals that provide X-ray powder diffraction patterns that are identical to the X-ray powder diffraction pattern shown in the Figures, and any crystals providing X-ray powder diffraction patterns substantially the same as those shown in the Figures fall within the scope of the present invention. A person skilled in the art of X-ray powder diffraction is able to judge the substantial identity of X-ray powder diffraction patterns.

Persons skilled in the art of X-ray powder diffraction will realise that the relative intensity of peaks can be affected by, for example, grains above 30μm in size and non-unitary aspect ratios, which may affect analysis of samples. The skilled person will also realise that the position of reflections can be affected by the precise height at which the sample sits in the diffractometer and the zero calibration of the diffractometer. The surface planarity of the sample may also have a small effect. Hence the diffraction pattern data presented are not to be taken as absolute values. (Jenkins, R & Snyder, R.L. 'Introduction to X-Ray Powder Diffractometry' John Wiley & Sons 1996; Bunn, C.W. (1948), Chemical Crystallography, Clarendon Press, London; Klug, H. P. & Alexander, L. E. (1974), X-Ray Diffraction Procedures).

Generally, a measurement error of a diffraction angle in an X-ray powder diffractogram is approximately plus or minus 0.2° 2-theta, and such degree of a measurement error should be taken into account when considering the X-ray powder diffraction pattern in the Figures and when reading data contained in the Tables included herein. Furthermore, it should be understood that intensities might fluctuate depending on experimental conditions and sample preparation (preferred orientation).

In this specification N-(2-{2-dimethylaminoethyl-methylamino}-4-methoxy-5-{[4-(1-methylindol-3-yl)pyrimidin-2-yl] amino }phenyl)prop-2-enamide is referred to as "Compound X". The initially produced Compound X was found to be an amorphous solid. Several useful crystalline polymorphic forms have subsequently been produced using the conditions described hereinafter in the experimental section. In all of the embodiments relating to solid forms recited herein, the peaks of the X-ray diffraction patterns are measured using CuKa radiation.

Chemical synthesis and biological assay procedures

The following abbreviations may be used: Abbreviations: THF = tetrahydrofuran; DIPEA = diisopropylethylamine; sat. = saturated aqueous solution; FCC = flash column chromatography using silica; TFA = trifluoroacetic acid; r.t. = room temperature; DMF = \(N,N\)-dimethylformamide; DMSO = dimethylsulfoxide; DMA = \(N,N\)-dimethylacetamide; EtOAc = ethyl acetate; h. = hour(s); Proton NMR: (1H NMR) was determined using deuterated dimethylsulfoxide at 400 or 500MHz at around 20-30°C, unless otherwise stated. Standard NMR abbreviations are used, (s = singlet; d = doublet; dd = double of doublets; t = triplet; q = quartet; p = pentet; m = multiplet; br = broad; etc.). Where iron was mentioned as a reagent, it was iron powder, 325 mesh and hydrogen reduced. Quoted assay values (µM) for a given Example are IC\(_{50}\) values. X-Ray Powder Diffraction (XRPD) was carried out using a Bruker D4 instrument. The X-ray powder diffractogram was determined by mounting a sample of the crystalline material on a Bruker single silicon crystal (SSC) wafer mount and spreading out the sample into a thin layer with the aid of a microscope slide. The sample was spun at 30 revolutions per minute (to improve counting statistics) and irradiated with X-rays generated by a copper long-fine focus tube operated at 40kV and 40mA with a wavelength of 1.5418 angstroms (CuKa radiation). The collimated X-ray source was passed through an automatic variable divergence slit set at V20 and the reflected radiation directed through a 5.89mm antiscatter slit and a 9.55mm detector slit. The sample was exposed for 0.03 seconds per 0.00570° 2-theta increment (continuous scan mode) over the range 2 degrees to 40 degrees 2-theta in theta-theta mode. The running time was 3 minutes and 36 seconds. The instrument was equipped with a Position sensitive detector (Lynxeye). Control and data capture was by means of a Dell Optiplex 686 NT 4.0 Workstation operating with Diffrac+ software. Differential Scanning Calorimetry (DSC) was carried out using a "TA Instruments Q1000 differential scanning calorimeter. Typically less than 5 mg of material contained in a standard aluminium pan fitted with a lid was heated over the temperature range 25°C to 300°C at a constant heating rate of 10°C per minute. A purge gas using nitrogen was used - flow rate 50mL per minute. Any crystal form that provides a XRPD diffractogram or DSC thermogram substantially
identical to those disclosed herein fall within the scope of the present inventions. One skilled in the art will have the ability to determine substantial identities of diffractograms and thermograms.

Assay 1: Exon 19 deletion EGFR (Activating Single Mutant) cellular phosphorylation assay
The human lung cell line PC9 (Exon 19 deletion EGFR) were obtained from the American type Culture Collection. PC9 were maintained in RPMI 1640, containing 10% fetal calf serum and 2mM glutamine. Cells were grown in a humidified incubator at 37°C with 5% CO₂. Assays to measure cellular phosphorylation of endogenous p-EGFR in cell lysates were carried out according to the protocol described in the R&D Systems DuoSet IC Human Phospho-EGF R ELISA (R&D Systems catalogue number #DYC1095).

40 μL of cells were seeded (10000 cells/well) in growth medium in Corning black, clear-bottomed 384-well plates and incubated at 37°C with 5% CO₂ overnight. Cells were acoustically dosed using an Echo 555, with compounds serially diluted in 100% DMSO. Plates were incubated for a further 2h, then following aspiration of medium, 40 μL 1x lysis buffer was added to each well. Greiner black high bind 384-well plates were coated with capture antibody and then blocked with 3% BSA. Following removal of block, 15 μL of lysate were transferred to the Greiner black high bind 384-well plates and incubated for 2 hours. Following aspiration and washing of the plates with PBS, 20 μL of detection antibody were added and incubated for 2 hours. Following aspiration and washing of the plates with PBS, 20 μL of QuantaBlu fluorogenic peroxidase substrate (Thermo Fisher Scientific catalogue number 15169) were added and incubated for 1 hour. 20 μL QuantaBlu stop solution were added to plates and fluorescence read on an Envision plate reader using Excitation 352nm wavelength and emission 460nm wavelength. The data obtained with each compound was exported into a suitable software package (such as Origin) to perform curve fitting analysis. From this data an IC₅₀ value was determined by calculation of the concentration of compound that is required to give a 50% effect.

**Example 1:** tv-4-Methoxy-2-{1-methyl-3,6-dihydro-2H-pyridin-4-yl}-5-[(5-methyl-4-pyrazolo[1,5-alpyridin-3-yl]pyrimidin-2-yl)aminol phenyljpr op-2-enamide

Acryloyl chloride (0.331 mL, 1M in THF, 0.33 mmol) was added dropwise to a solution of 6-methoxy-4-(1-methyl-1,2,3,6-tetrahydropyridin-4-yl)-7Vi-[5-methyl-4-(pyrazolo[1,5-a]-pyridin-3-yl)pyrimidin-2-yl]benzene-1,3-diamine (Intermediate 1, 146 mg, 0.33 mmol) and DIPEA (0.086 mL, 0.50 mmol) in THF (4 mL) at -10°C over a period of 1 minute under N₂. The resulting mixture was stirred at 0°C for 15 minutes and then concentrated in vacuo. The residue was dissolved in CH₂C₁₂ (5 mL) plus a little CH₃OH. This solution was then washed with sat. NaHCO₃ (2 mL), dried (MgSO₄) and then concentrated in vacuo.

Purification by FCC, eluting with 5-25% CH₃OH in CH₂C₁₂ and concentration of appropriate fractions in vacuo provided material that was dissolved in CH₂C₁₂;7N methanolic ammonia 100:8 (1 mL) and filtered through a 1g silica plug. Concentration of the resulting solution provided the title compound (70 mg, 38%) as a pale orange foam; H NMR: 2.27 (3H, s), 2.37 (2H, m), 2.42 (3H, s), 2.53-2.57 (2H, m), 2.97 (2H, m), 3.87 (3H, d), 5.66 (2H, d), 6.14 (1H, d), 6.39 (1H, d), 6.86 (1H, s), 7.07 (1H, t), 7.42 (1H, m), 7.98 (1H, s), 8.17 (1H, s), 8.32 (1H, s), 8.48 (1H, d), 8.58 (1H, s), 8.81 (1H, d), 9.29 (1H, s); m/z: ES⁺ MH⁺ 496.

Acryloyl chloride (0.217 mL, 1M in THF, 0.22 mmol) was added dropwise to a slurry of N’-[5-chloro-4-(1-H-indol-3-yl)pyrimidin-2-yl]-4-methoxy-6-(1-methyl-3,6-dihydro-2H-pyridin-4-yl)benzene-1,3-diamine (Intermediate 7, 100 mg, 0.22 mmol) and DIPEA (0.057 mL, 0.33 mmol) in THF (3 mL) at -5°C over a period of 1 minute under N₂. The resulting mixture was stirred at 0°C for 15 minutes and then concentrated in vacuo. The residue was dissolved in CH₂C₁₂ (5 mL) plus a few drops of CH₃OH, and washed with sat. NaHCO₃ (2 mL). The organic solution was then dried (MgSO₄) and loaded onto silica in vacuo. Purification by FCC, eluting with 5-25% CH₃OH in CH₂C₁₂ and concentration of appropriate fractions in vacuo provided a residue that was washed with CH₃OH (0.3 mL) and dried in air to give the title compound (37 mg, 31%) as a beige crystalline solid. Acryloyl chloride (0.025 mL, 0.30 mmol) was added dropwise to N’-[4-((1H-indol-3-yl)-5-methylpyrimidin-2-yl]-4-methoxy-6-(4-methylpiperazin-1-yl)benzene-1,3-diamine (Intermediate 12, 135 mg, 0.30 mmol) and DIPEA (0.090 mL, 0.33 mmol) in CH$_2$C$_2$ (10 mL) and DMF (2 mL) at 0°C under N$_2$. The resulting suspension was stirred at 0°C for 2h. Then allowed to warm to r.t. The mixture was then diluted with water (15 mL) and extracted with CH$_2$C$_2$ (40 mL). Polymorphic Form K of Compound X

This polymorphic form of Compound X was produced according to the following method:

A solution of acryloyl chloride (0.026 L, 318.48 mmol) in CH₂C₁₂ (290 mL) was added dropwise over 25 minutes to a stirred suspension of N₂,N₂,N₂,N₂-tetramethyl-2-(dimethylamino)ethyl)-5-methoxy-2-(1H-indol-3-yl)pyrimidin-2-yl)benzene-1,2,4-triamine (129 g, 289.52 mmol) in CH₂C₁₂ (2.9 L) that was cooled to -5°C. The addition was exothermic but the mixture was not permitted to warm to more than 1°C during the addition. The resulting mixture was stirred at -5 °C for 2h. Cold sat. NaHCO₃ solution (1L) was then added dropwise, while keeping the temperature below -2°C. The mixture was then allowed to warm to r.t. The phases were separated, and the resulting organic solution was washed with water (100 mL) and saturated brine (100 mL). The solution was then dried (MgSO₄) and concentrated in vacuo. The residue was dissolved into 5% CH₃OH in CH₂C₁₂ (60 mL) and then filtered. The filtered solution was purified by FCC, eluting with 5% CH₃OH in CH₂C₁₂ and clean fractions were combined and concentrated to give impure Compound X as a brown gum (96 g). Further purification by chiral preparative HPLC provided a sample of Compound X which was slurried in CH₃OH (50 mL). Not all of the Compound X material would dissolve. Water was then added (250 mL) and the resulting mixture was slurried overnight with magnetic stirring. The resulting solid was then collected by filtration and dried in a vacuum oven over a weekend to provide 16.2 g of Compound X in the polymorphic form defined herein as Form K.
