BACKGROUND OF THE INVENTION

Phosphatidylinositol (hereinafter abbreviated as "PI") is one of a number of phospholipids found in cell membranes. In recent years it has become clear that PI plays an important role in intracellular signal transduction. Cell signaling via 3'-phosphorylated phosphoinositides has been implicated in a variety of cellular processes, e.g., malignant transformation, growth factor signaling, inflammation, and immunity (Rameh et al. (1999) J. Biol Chem, 274:8347-8350). The enzyme responsible for generating these phosphorylated signaling products, phosphatidylinositol 3-kinase (also referred to as PI 3-kinase or PI3K), was originally identified as an activity associated with viral oncoproteins and growth factor receptor tyrosine kinases that phosphorylate phosphatidylinositol (PI) and its phosphorylated derivatives at the 3'-hydroxyl of the inositol ring (Panayotou et al (1992) Trends Cell Biol 2:358-60).

Phosphoinositide 3-kinases (PI3K) are lipid kinases that phosphorylate lipids at the 3-hydroxyl residue of an inositol ring (Whitman et al (1988) Nature, 332:664). The 3-phosphorylated phospholipids (PIP3s) generated by PI3-kinases act as second messengers recruiting kinases with lipid binding domains (including plekstrin homology (PH) regions), such as Akt and phosphoinositide-dependent kinase-1 (PDK1). Binding of Akt to membrane PIP3s causes the translocation of Akt to the plasma membrane, bringing Akt into contact with PDK1, which is responsible for activating Akt. The tumor-suppressor phosphatase, PTEN, dephosphorylates PIP3 and therefore acts as a negative regulator of Akt activation. The PI3-kinases Akt and PDK1 are important in the regulation of many cellular processes including cell...

[0064] A "metabolite" is a product produced through metabolism in the body of a specified compound or salt thereof. Metabolites of a compound may be identified using routine techniques known in the art and their activities determined using tests such as those described herein. Such products may result for example from the oxidation, reduction, hydrolysis, amidation, deamidation, esterification, deesterification, enzymatic cleavage, and the like, of the administered compound. Accordingly, the invention includes metabolites of compounds of the invention, including compounds produced by a process comprising contacting a compound of this invention with a mammal for a period of time sufficient to yield a metabolic product thereof.

[0065] The term "package insert" is used to refer to instructions customarily included in
commercial packages of therapeutic products, that contain information about the indications, usage, dosage, administration, contraindications and/or warnings concerning the use of such therapeutic products.

[0066] The term "chiral" refers to molecules which have the property of non-superimposability of the mirror image partner, while the term "achiral" refers to molecules which are superimposable on their mirror image partner.

[0067] The term "stereoisomers" refers to compounds which have identical chemical constitution, but differ with regard to the arrangement of the atoms or groups in space.

[0068] "Diastereomer" refers to a stereoisomer with two or more centers of chirality and whose molecules are not mirror images of one another. Diastereomers have different physical properties, e.g. melting points, boiling points, spectral properties, and reactivities. Mixtures of diastereomers may separate under high resolution analytical procedures such as electrophoresis and chromatography.

[0069] "Enantiomers" refer to two stereoisomers of a compound which are non-superimposable mirror images of one another.

[0070] Stereochemical definitions and conventions used herein generally follow S. P. Parker, Ed., McGraw-Hill Dictionary of Chemical Terms (1984) McGraw-Hill Book Company, New York; and Eliei, E. and Wilen, S., "Stereochemistry of Organic Compounds", John Wiley & Sons, Inc., New York, 1994. The compounds of the invention may contain asymmetric or chiral centers, and therefore exist in different stereoisomeric forms. It is intended that all stereoisomeric forms of the compounds of the invention, including but not limited to, diastereomers, enantiomers and atropisomers, as well as mixtures thereof such as racemic mixtures, form part of the present invention. Many organic compounds exist in optically active forms, i.e., they have the ability to rotate the plane of plane-polarized light. In describing an optically active compound, the prefixes D and L, or R and S, are used to denote the absolute configuration of the molecule about its chiral center(s). The prefixes d and 1 or (+) and (-) are employed to designate the sign of rotation of plane-polarized light by the compound, with (-) or 1 meaning that the compound is levorotatory. A compound prefixed with (+) or d is dextrorotatory. For a given chemical structure, these stereoisomers are identical except that they are mirror images of one another. A specific stereoisomer may also be referred to as an enantiomer, and a mixture of such isomers is often called an enantiomeric mixture. A 50:50 mixture of enantiomers is referred to as a racemic mixture or a racemate, which may occur where there has been no stereoselection or stereospecificity in a chemical reaction or process.

The terms "racemic mixture" and "racemate" refer to an equimolar mixture of two enantiomeric species, devoid of optical activity.
The term "tautomer" or "tautomeric form" refers to structural isomers of different energies which are interconvertible via a low energy barrier. For example, proton tautomers (also known as prototropic tautomers) include interconversions via migration of a proton, such as keto-enol and imine-enamine isomerizations. Valence tautomers include interconversions by reorganization of some of the bonding electrons.

The phrase "pharmacetically acceptable salt" as used herein, refers to pharmaceutically acceptable organic or inorganic salts of a compound of the invention. Exemplary salts include, but are not limited, to sulfate, citrate, acetate, oxalate, chloride, bromide, iodide, nitrate, bisulfate, phosphate, acid phosphate, isonicotinate, lactate, salicylate, acid citrate, tartrate, oleate, tannate, pantothenate, bitartrate, ascorbate, succinate, maleate, gentisinate, fumarate, gluconate, glucuronate, saccharate, formate, benzoate, glutamate, methanesulfonate "mesylate", ethanesulfonate, benzenesulfonate, /?-toluenesulfonate, and pamoate (i.e., 1,1'-methylene-bis(2-hydroxy-3-naphthoate)) salts. A pharmaceutically acceptable salt may involve the inclusion of another molecule such as an acetate ion, a succinate ion or other counter ion. The counter ion may be any organic or inorganic moiety that stabilizes the charge on the parent compound. Furthermore, a pharmaceutically acceptable salt may have more than one charged atom in its structure. Instances where multiple charged atoms are part of the pharmaceutically acceptable salt can have multiple counter ions. Hence, a pharmaceutically acceptable salt can have one or more charged atoms and/or one or more counter ion.

If the compound of the invention is a base, the desired pharmaceutically acceptable salt may be prepared by any suitable method available in the art, for example, treatment of the free base with an inorganic acid, such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, methanesulfonic acid, phosphoric acid and the like, or with an organic acid, such as acetic acid, trifluoroacetic acid, maleic acid, succinic acid, mandelic acid, fumaric acid, malonic acid, pyruvic acid, oxalic acid, glycolic acid, salicylic acid, a pyranosidyl acid, such as glucuronic acid or galacturonic acid, an alpha hydroxy acid, such as citric acid or tartaric acid, an amino acid, such as aspartic acid or glutamic acid, an aromatic acid, such as benzoic acid or cinnamic acid, a sulfonic acid, such as p-toluenesulfonic acid or ethanesulfonic acid, or the like.

If the compound of the invention is an acid, the desired pharmaceutically acceptable salt may be prepared by any suitable method, for example, treatment of the free acid with an inorganic or organic base, such as an amine (primary, secondary or tertiary), an alkali metal hydroxide or alkaline earth metal hydroxide, or the like. Illustrative examples of suitable salts include, but are not limited to, organic salts derived from amino acids, such as glycine and arginine, ammonia, primary, secondary, and tertiary amines, and cyclic amines, such as
piperidine, morpholine and piperazine, and inorganic salts derived from sodium, calcium, potassium, magnesium, manganese, iron, copper, zinc, aluminum and lithium.

The phrase "pharmaceutically acceptable" indicates that the substance or composition must be compatible chemically and/or toxicologically, with the other ingredients comprising a formulation, and/or the mammal being treated therewith.

A "solvate" refers to an association or complex of one or more solvent molecules and a compound of the invention. Examples of solvents that form solvates include, but are not limited to, water, isopropanol, ethanol, methanol, DMSO, ethylacetate, acetic acid, and ethanolamine.

The terms "compound of this invention," and "compounds of the present invention" and "compounds of Formula I" include compounds of Formulas I and stereoisomers, geometric isomers, tautomers, solvates, metabolites, and pharmaceutically acceptable salts and prodrugs thereof.

PREPARATION OF FORMULA I COMPOUNDS

Benzoxepin compounds of Formula I may be synthesized by synthetic routes that include processes analogous to those well-known in the chemical arts, particularly in light of the description contained herein. The starting materials are generally available from commercial sources such as Aldrich Chemicals (Milwaukee, WI) or are readily prepared using methods well known to those skilled in the art (e.g., prepared by methods generally described in Louis F. Fieser and Mary Fieser, *Reagents for Organic Synthesis*, v. 1-23, Wiley, N.Y. (1967-2006 ed.), or *Beilsteins Handbuch der organischen Chemie*, 4, Aufl. ed. Springer-Verlag, Berlin, including
supplements (also available via the Beilstein online database).

Compounds of Formula I may be prepared singly or as compound libraries comprising at least 2, for example 5 to 1,000 compounds, or 10 to 100 compounds. Libraries of compounds of Formula I may be prepared by a combinatorial 'split and mix' approach or by multiple parallel syntheses using either solution phase or solid phase chemistry, by procedures known to those skilled in the art. Thus according to a further aspect of the invention there is provided a compound library comprising at least 2 compounds, or pharmaceutically acceptable salts thereof.

For illustrative purposes, Schemes 1-8 show general methods which may be applied for preparation of Formula I compounds, as well as key intermediates. The General Procedures and Examples sections contain more detailed description of individual reaction steps. Those skilled in the art will appreciate that other synthetic routes may be used to synthesize the inventive compounds. Although certain starting materials and routes are depicted in the Schemes, General Procedures and Examples, other similar starting materials and routes can be substituted to provide a variety of derivatives and/or reaction conditions. In addition, many of the compounds prepared by the methods described below can be further modified in light of this disclosure using conventional chemistry well known to those skilled in the art.

In preparing compounds of Formulas I, protection of remote functionality (e.g., primary or secondary amine) of intermediates may be necessary. The need for such protection will vary depending on the nature of the remote functionality and the conditions of the preparation methods. Suitable amino-protecting groups include acetyl, trifluoroacetyl, t-butoxycarbonyl (BOC), benzyloxycarbonyl (CBz) and 9-fluorenylmethyleneoxycarbonyl (Fmoc). The need for such protection is readily determined by one skilled in the art. For a general description of protecting groups and their use, see T. W. Greene, Protective Groups in Organic Synthesis, John Wiley & Sons, New York, Third Ed., 1999.
Scheme 1

[00145] Scheme 1 shows a general method for preparation of 3,4-dihydrobenzo[b]oxepin-5(2H)-one intermediates 66 by O-alkylation of a phenolic compound with ethyl 4-bromobutanoate to give a ethyl 4-phenoxybutanoate intermediate 67, followed by saponification to the carboxylic acid 68 and intramolecular cyclization under acidic conditions.

Scheme 2

[00146] Scheme 2 shows a general method of preparation of N,N-disubstituted 4,5-dihydrobenzo[b]thieno[2,3-d]oxepine-2-carboxamide intermediates 69. 3,4-Dihydrobenzo[b]oxepin-5(2H)-one intermediates 66 are formylated with phosphorus oxytrichloride and dimethylformamide (DMF) to give 5-chloro-2,3-dihydrobenzo[b]oxepine-4-carbaldehyde intermediate 70. Cyclization of 70 with a mercapto acetate ester (HSCH$_2$CO$_2$R where R is alkyl or aryl) in potassium carbonate and DMF gives the 4,5-dihydrobenzo[b]thieno[2,3-d]oxepine-2-carboxylate ester intermediate 71. Saponification of 71 with lithium hydroxide in THF and water gives the acid (R = H) which is treated with thionyl chloride at reflux followed by a secondary amine (HNR$_5^5$R$_6^6$), such as N-methyl-2-chloroaniline, with a catalytic amount of DMAP (4,4-dimethylaminopyridine), triethylamine, and
dichloromethane to give 4,5-dihydrobenzo[b]thieno[2,3-d]oxepine-2-carboxamide intermediates 69. Alternatively, the acid is treated with oxalyl chloride and a catalytic amount of DMF to generate the acid chloride, followed by reaction with the amine and potassium carbonate in acetonitrile to give amides such as 69. Where one of R₁, R₂, R₃, or R₄ is bromo, the bromine of 69, or of another intermediate such as 66, 70, 71, may be displaced by: (i) carbynylative animation to give amide (-NR R²C(=O))R₃, (ii) formylation (-CHO) followed by reductive amination to -CH R₄NR R₅, (iii) Suzuki coupling with aryl or heteroaryl, (iv) Sonogashira coupling to give alkylnyl (-C≡CR₆), or (v) amination (-NR R₇ R₈).

[00147] A variety of palladium catalysts can be used during the Suzuki coupling step to form compounds where R₁, R₂, R₃, or R₄ is aryl or heteroaryl. Suzuki coupling is a palladium mediated cross coupling reaction of an arylhalide, with a boronic acid or boronate esters such as pinacolato. Low valent, Pd(II) and Pd(O) catalysts may be used, including PdCl₂(PPh₃)₂, Pd(t-Bu)₂, PdCl₂(dppe)₂Cl₂, Pd(PPh₃)₄, Pd(OAc)/PPh₃, Cl₂Pd((PPh₃)₂), Pd(DIPHOS)₃, Cl₂Pd(Bipy), [PdCl(PPh₃)₄], Cl₂Pd[O(o-tol)]₃, Cl₂Pd[O(o-tol)]₃, Pd₂(dbac)₃, Pd₂(dbac)₃, and encapsulated catalysts Pd EnCat™ 30, Pd EnCat™ 30, and Pd(II)EnCat™ BINAP 30 (US 2004/0254066).

[00148] A variety of solid adsorbant palladium scavengers can be used to remove palladium after the Suzuki coupling step. Exemplary embodiments of palladium scavengers include FLORISIL® and SILABOND® Thiourea. Other palladium scavengers include silica gel, controlled-pore glass (TosoHaas), and derivatized low crosslinked polystyrene QuadraPure™ AEA, QuadraPure™ IMDAZ, QuadraPure™ MPA, QuadraPure™ TU (Reaxa Ltd., Sigma-Aldrich Chemical Co.).

Scheme 4

Scheme 4 shows a general method of preparation of benzoxepin thiophene amides 78. Cyclization of 3-(2-(2-halophenoxy)ethyl)thiophene intermediate 75 (X = Br, I, Cl) under palladium catalysis (see Example 8) gives 4,5-dihydrobenzo[b]thieno[2,3-d]oxepine intermediates 74. Bromination of the 2-position gives 2-bromo-4,5-dihydrobenzo[b]thieno[2,3-d]oxepine intermediates 76 which can be reacted with aryl isocyanate (Ar-NCO) or aryl isothiocyanate (Ar-NCS) reagents to give N-phenyl-4,5-dihydrobenzo[b]thieno[2,3-d]oxepine-2-carboxamide intermediates 77 (Y = O, S). The N-H group of 77 can be selectively alkylated to give 78.

Scheme 5
Scheme 5 shows a general method of Suzuki coupling of a 2-bromo-4,5-dihydrobenzo[b]thieno[2,3-d]oxepine intermediate 76 with a heterocyclyl boronate reagent, such as 2-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)pyridine to give the 2-(4,5-dihydrobenzo[b]thieno[2,3-d]oxepin-2-yl)pyridine 79a.

Scheme 6

Scheme 6 shows a general method forming a thiophenyl benzoxepin boronate compound 80 by reaction of 2-bromo-4,5-dihydrobenzo[b]thieno[2,3-d]oxepine intermediate 76 with a heterocyclyl boronate reagent, such as 2-isopropoxy-4,4,5,5-tetramethyl-l,3,2-dioxaborolane. Boronate 80 undergoes Suzuki coupling with a heterocyclyl halide reagent, such as 3-iodopyridine to give 3-(4,5-dihydrobenzo[b]thieno[2,3-d]oxepin-2-yl)pyridine 79b.

Scheme 7

Scheme 7 shows a general method for substitution at the 2-position of 4,5-
dihydrobenzo[b]thieno[2,3-d]oxepine intermediates 7 by acylation with a carboxylic acid such as 2-phenylacetic acid to give 1-(4,5-dihydrobenzo[b]thieno[2,3-d]oxepin-2-yl)-2-phenylethanone intermediate 81. Bromination gives 2-bromo-1-(4,5-dihydrobenzo[b]thieno[2,3-d]oxepin-2-yl)-2-phenylethanone intermediate 82. Cyclization with a thioamide compound gives 4-(4,5-dihydrobenzo[b]thieno[2,3-d]oxepin-2-yl)-5-phenylthiazole 83.

Scheme 8

[00154] Scheme 8 shows a general method for regiospecific alkylation of 4,5-dihydropyrido[4,3-b]thieno[2,3-d]oxepin-2-yl intermediates 84 oxidation to form the N-oxide 85, and alkylation to give 10-substituted 4,5-dihydropyrido[4,3-b]thieno[2,3-d]oxepin-2-yl 86.

METHODS OF SEPARATION

In the methods of preparing the compounds of this invention, it may be advantageous to separate reaction products from one another and/or from starting materials. The desired products of each step or series of steps is separated and/or purified (hereinafter separated) to the desired degree of homogeneity by the techniques common in the art. Typically such separations involve multiphase extraction, crystallization from a solvent or solvent mixture, distillation, sublimation, or chromatography. Chromatography can involve any number of methods including, for example: reverse-phase and normal phase; size exclusion; ion exchange; high, medium and low pressure liquid chromatography methods and apparatus; small scale analytical; simulated moving bed (SMB) and preparative thin or thick layer chromatography, as well as techniques of small scale thin layer and flash chromatography.

Another class of separation methods involves treatment of a mixture with a
reagent selected to bind to or render otherwise separable a desired product, unreacted starting material, reaction by product, or the like. Such reagents include adsorbents or absorbents such as activated carbon, molecular sieves, ion exchange media, or the like. Alternatively, the reagents can be acids in the case of a basic material, bases in the case of an acidic material, binding reagents such as antibodies, binding proteins, selective chelators such as crown ethers, liquid/liquid ion extraction reagents (LIX), or the like.

Selection of appropriate methods of separation depends on the nature of the materials involved. For example, boiling point and molecular weight in distillation and sublimation, presence or absence of polar functional groups in chromatography, stability of materials in acidic and basic media in multiphase extraction, and the like. One skilled in the art will apply techniques most likely to achieve the desired separation.

Diastereomeric mixtures can be separated into their individual diastereomers on the basis of their physical chemical differences by methods well known to those skilled in the art, such as by chromatography and/or fractional crystallization. Enantiomers can be separated by converting the enantiomeric mixture into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., chiral auxiliary such as a chiral alcohol or Mosher's acid chloride), separating the diastereomers and converting (e.g., hydrolyzing) the individual diastereoisomers to the corresponding pure enantiomers. Also, some of the compounds of the present invention may be atropisomers (e.g., substituted biaryls) and are considered as part of this invention. Enantiomers can also be separated by use of a chiral HPLC column.

A single stereoisomer, e.g., an enantiomer, substantially free of its stereoisomer may be obtained by resolution of the racemic mixture using a method such as formation of diastereomers using optically active resolving agents (Eliel, E. and Wilen, S. "Stereochemistry of Organic Compounds," John Wiley & Sons, Inc., New York, 1994; Lochmuller, C. H., (1975) J. Chromatogr., 113(3):283-302). Racemic mixtures of chiral compounds of the invention can be separated and isolated by any suitable method, including: (1) formation of ionic, diastereomeric salts with chiral compounds and separation by fractional crystallization or other methods, (2) formation of diastereomeric compounds with chiral derivatizing reagents, separation of the diastereomers, and conversion to the pure stereoisomers, and (3) separation of the substantially pure or enriched stereoisomers directly under chiral conditions. See: "Drug Stereochemistry, Analytical Methods and Pharmacology," Irving W. Wainer, Ed., Marcel Dekker, Inc., New York (1993).

Under method (1), diastereomeric salts can be formed by reaction of enantiomerically pure chiral bases such as brucine, quinine, ephedrine, strychnine, α-methyl-β-phenylethylamine (amphetamine), and the like with asymmetric compounds bearing acidic
functionality, such as carboxylic acid and sulfonic acid. The diastereomeric salts may be induced to separate by fractional crystallization or ionic chromatography. For separation of the optical isomers of amino compounds, addition of chiral carboxylic or sulfonic acids, such as camphorsulfonic acid, tartaric acid, mandelic acid, or lactic acid can result in formation of the diastereomeric salts.

[00171] Alternatively, by method (2), the substrate to be resolved is reacted with one enantiomer of a chiral compound to form a diastereomeric pair (E. and Wilen, S. "Stereochemistry of Organic Compounds", John Wiley & Sons, Inc., 1994, p. 322). Diastereomeric compounds can be formed by reacting asymmetric compounds with enantiomERICALLY pure chiral derivatizing reagents, such as menthyl derivatives, followed by separation of the diastereomers and hydrolysis to yield the pure or enriched enantiomer. A method of determining optical purity involves making chiral esters, such as a menthyl ester, e.g., (-) menthyl chloroformate in the presence of base, or Mosher ester, \( \alpha \)-methoxy-\( \alpha \)-(trifluoromethyl)phenyl acetate (Jacob III. J. Org. Chem. (1982) 47:4165), of the racemic mixture, and analyzing the \( ^1H \) NMR spectrum for the presence of the two atropisomeric enantiomers or diastereomers. Stable diastereomers of atropisomeric compounds can be separated and isolated by normal- and reverse-phase chromatography following methods for separation of atropisomeric naphthyl-isoquinolines (WO 96/15111). By method (3), a racemic mixture of two enantiomers can be separated by chromatography using a chiral stationary phase ("Chiral Liquid Chromatography" (1989) W. J. Lough, Ed., Chapman and Hall, New York; Okamoto, J. Chromatogr., (1990) 513:375-378). Enriched or purified enantiomers can be distinguished by methods used to distinguish other chiral molecules with asymmetric carbon atoms, such as optical rotation and circular dichroism.

[00172] BIOLOGICAL EVALUATION

[00173] Determination of the PI3 kinase activity of a Formula I or Formula II compound is possible by a number of direct and indirect detection methods. Certain exemplary compounds described herein were assayed for their p110a (alpha), and other isoform, PI3K binding activity (Example 275) and \textit{in vitro} activity against tumor cells (Example 276). The range of PI3K binding activities was less than 1 nM (nanomolar) to about 10 \( \mu \)M (micromolar). Certain exemplary compounds of the invention had PI3K binding activity \( I_{50} \) values less than 10 nM. Certain compounds of the invention had tumor cell-based activity \( I_{50} \) values less than 100 nM.

[00174] The cytotoxic or cytostatic activity of Formula I and II exemplary compounds was measured by: establishing a proliferating mammalian tumor cell line in a cell culture medium, adding a Formula I compound, culturing the cells for a period from about 6 hours to about 5 days; and measuring cell viability (Example 276). Cell-based \textit{in vitro} assays were used
to measure viability, i.e. proliferation (IC$_{50}$), cytotoxicity (EC$_{50}$), and induction of apoptosis (caspase activation).

[00175] The in vitro potency of Formula I and II exemplary compounds was measured by the cell proliferation assay, CellTiter-Glo® Luminescent Cell Viability Assay, commercially available from Promega Corp., Madison, WI (Example 276). This homogeneous assay method is based on the recombinant expression of Coleoptera luciferase (US 5583024; US 5674713; US 5700670) and determines the number of viable cells in culture based on quantitation of the ATP present, an indicator of metabolically active cells (Crouch et al (1993) J. Immunol. Meth. 160:81-88; US 6602677). The CellTiter-Glo® Assay was conducted in 96 or 384 well format, making it amenable to automated high-throughput screening (HTS) (Cree et al (1995) Anticancer Drugs 6:398-404). The homogeneous assay procedure involves adding the single reagent (CellTiter-Glo® Reagent) directly to cells cultured in serum-supplemented medium. Cell washing, removal of medium and multiple pipetting steps are not required. The system detects as few as 15 cells/well in a 384-well format in 10 minutes after adding reagent and mixing.

[00176] The homogeneous "add-mix-measure" format results in cell lysis and generation of a luminescent signal proportional to the amount of ATP present. The amount of ATP is directly proportional to the number of cells present in culture. The CellTiter-Glo® Assay generates a "glow-type" luminescent signal, produced by the luciferase reaction, which has a half-life generally greater than five hours, depending on cell type and medium used. Viable cells are reflected in relative luminescent units (RLU). The substrate, Beetle Luciferin, is oxidatively decarboxylated by recombinant firefly luciferase with concomitant conversion of ATP to AMP and generation of photons. The extended half-life eliminates the need to use reagent injectors and provides flexibility for continuous or batch mode processing of multiple plates. This cell proliferation assay an be used with various multiwell formats, e.g. 96 or 384 well format. Data can be recorded by luminometer or CCD camera imaging device. The luminescence output is presented as relative light units (RLU), measured over time.

[00177] The antiproliferative effects of Formula I and II exemplary compounds were measured by the CellTiter-Glo® Assay (Example 276) against several tumor cell lines, including PC3, Detroit 562, and MDAMB361.1. EC$_{50}$ values were established for the tested compounds. The range of in vitro cell potency activities was about 100 nM to about 10 µM.

[00178] Certain ADME properties were measured for certain exemplary compounds by assays including: Caco-2 Permeability (Example 277), Hepatocyte Clearance (Example 278), Cytochrome P450 Inhibition (Example 279), Cytochrome P450 Induction (Example 280), Plasma Protein Binding (Example 281), and hERG channel blockage (Example 282).
Certain exemplary compounds were tested for efficacy by a dose escalation studies by administration in tumor xenograft Taconic nude mouse models (Example 283). The breast cancer cell line MDA-MB-361.1 mouse model was administered Compound 223 along with Vehicle (MCT, negative control). The tumor growth delay was measured when dosed orally daily for 21 days at 50 and 100 mg/kg (Figure 3). Body weight change over the course of treatment was measured as an indicator of safety. The body weights of the group administered Compound 223 at 50 and 100 mg/kg did not significantly differ from the group administered Vehicle. Treatment of the MDA-MB-361.1 mouse model with Compound 328 caused tumor growth inhibition when dosed orally daily for 21 days at 25, 50 and 100 mg/kg (Figure 4). At least one of the 10 mice treated at 25 mg/kg showed a partial response. The body weights of the group administered Compound 328 at 50 and 100 mg/kg did not significantly differ from the group administered Vehicle. Treatment of the MDA-MB-361.1 mouse model with Compound 345 caused tumor growth inhibition when dosed orally daily for 21 days at 12.5, 25 and 50 mg/kg (Figure 5). The body weights of the group administered Compound 345 at 12.5, 25, and 50 mg/kg did not significantly differ from the group administered Vehicle. In each study, Compounds 223, 328, and 345 suppressed pAkt (phospho-Akt), a potential biomarker of PI3K signal transduction disruption (Example 284).

Exemplary Formula I compounds No. 101-533 in Table 1, were made, characterized, and tested for PI3K activity according to the methods of this invention, and have the following structures and corresponding names (ChemDraw Ultra, Version 9.0.1, CambridgeSoft Corp., Cambridge MA).

ADMINISTRATION OF COMPOUNDS OF FORMULA I and II

The Formula I and II compounds of the invention may be administered by any route appropriate to the condition to be treated. Suitable routes include oral, parenteral (including subcutaneous, intramuscular, intravenous, intraarterial, intradermal, intrathecal and epidural), transdermal, rectal, nasal, topical (including buccal and sublingual), vaginal, intraperitoneal, intrapulmonary and intranasal. For local immunosuppressive treatment, the compounds may be administered by intralesional administration, including perfusing or otherwise contacting the graft with the inhibitor before transplantation. It will be appreciated that the preferred route may vary with for example the condition of the recipient. Where the compound is administered orally, it may be formulated as a pill, capsule, tablet, etc. with a pharmaceutically acceptable carrier or excipient. Where the compound is administered parenterally, it may be formulated with a pharmaceutically acceptable parenteral vehicle and in a unit dosage injectable form, as detailed below.

A dose to treat human patients may range from about 10 mg to about 1000 mg of Formula I or II compound. A typical dose may be about 100 mg to about 300 mg of the compound. A dose may be administered once a day (QID), twice per day (BID), or more frequently, depending on the pharmacokinetic and pharmacodynamic properties, including absorption, distribution, metabolism, and excretion of the particular compound. In addition, toxicity factors may influence the dosage and administration regimen. When administered orally, the pill, capsule, or tablet may be ingested daily or less frequently for a specified period of time. The regimen may be repeated for a number of cycles of therapy.

METHODS OF TREATMENT WITH FORMULA I and II COMPOUNDS

Compounds of the present invention are useful for treating hyperproliferative diseases, conditions and disorders including, but not limited to, those characterized by over expression of lipid kinases, e.g. PB kinase. Accordingly, another aspect of this invention includes methods of treating or preventing diseases or conditions that can be treated or prevented by inhibiting lipid kinases, including PI3. In one embodiment, the method comprises administering to a mammal in need thereof a therapeutically effective amount of a compound of Formula I, or a stereoisomer, geometric isomer, tautomer, or pharmaceutically acceptable salt thereof. In one embodiment, a human patient is treated with a compound of Formula I and a pharmaceutically acceptable carrier, adjuvant, or vehicle, wherein said compound of Formula I is present in an amount to detectably inhibit PI3 kinase activity.

Cancers which can be treated according to the methods of this invention include, but are not limited to, breast, ovary, cervix, prostate, testis, genitourinary tract, esophagus, larynx, glioblastoma, neuroblastoma, stomach, skin, keratoacanthoma, lung, epidermoid
carcinoma, large cell carcinoma, non-small cell lung carcinoma (NSCLC), small cell carcinoma, lung adenocarcinoma, bone, colon, adenoma, pancreas, adenocarcinoma, thyroid, follicular carcinoma, undifferentiated carcinoma, papillary carcinoma, seminoma, melanoma, sarcoma, bladder carcinoma, liver carcinoma and biliary passages, kidney carcinoma, myeloid disorders, lymphoid disorders, hairy cells, buccal cavity and pharynx (oral), lip, tongue, mouth, pharynx, small intestine, colon-rectum, large intestine, rectum, brain and central nervous system, Hodgkin's and leukemia.

Another aspect of this invention provides a compound of this invention for use in the treatment of the diseases or conditions described herein in a mammal, for example, a human, suffering from such disease or condition. Also provided is the use of a compound of this invention in the preparation of a medicament for the treatment of the diseases and conditions described herein in a warm-blooded animal, such as a mammal, for example a human, suffering from such disorder.

PHARMACEUTICAL FORMULATIONS
In order to use a compound of this invention for the therapeutic treatment (including prophylactic treatment) of mammals including humans, it is normally formulated in accordance with standard pharmaceutical practice as a pharmaceutical composition. According to this aspect of the invention there is provided a pharmaceutical composition comprising a compound of this invention in association with a pharmaceutically acceptable diluent or carrier.

A typical formulation is prepared by mixing a compound of the present invention and a carrier, diluent or excipient. Suitable carriers, diluents and excipients are well known to those skilled in the art and include materials such as carbohydrates, waxes, water soluble and/or swellable polymers, hydrophilic or hydrophobic materials, gelatin, oils, solvents, water and the like. The particular carrier, diluent or excipient used will depend upon the means and purpose for which the compound of the present invention is being applied. Solvents are generally selected based on solvents recognized by persons skilled in the art as safe (GRAS) to be administered to a mammal. In general, safe solvents are non-toxic aqueous solvents such as water and other non-toxic solvents that are soluble or miscible in water. Suitable aqueous solvents include water, ethanol, propylene glycol, polyethylene glycols (e.g., PEG 400, PEG 300), etc. and mixtures thereof. The formulations may also include one or more buffers, stabilizing agents, surfactants, wetting agents, lubricating agents, emulsifiers, suspending agents, preservatives, antioxidants, opaquing agents, glidants, processing aids, colorants, sweeteners, perfuming agents, flavoring agents and other known additives to provide an elegant presentation of the drug (i.e., a compound of the present invention or pharmaceutical composition thereof) or aid in the manufacturing of the pharmaceutical product (i.e., medicament).
The formulations may be prepared using conventional dissolution and mixing procedures. For example, the bulk drug substance (i.e., compound of the present invention or stabilized form of the compound (e.g., complex with a cyclodextrin derivative or other known complexation agent) is dissolved in a suitable solvent in the presence of one or more of the excipients described above. The compound of the present invention is typically formulated into pharmaceutical dosage forms to provide an easily controllable dosage of the drug and to enable patient compliance with the prescribed regimen.

The pharmaceutical composition (or formulation) for application may be packaged in a variety of ways depending upon the method used for administering the drug. Generally, an article for distribution includes a container having deposited therein the pharmaceutical formulation in an appropriate form. Suitable containers are well known to those skilled in the art and include materials such as bottles (plastic and glass), sachets, ampoules, plastic bags, metal cylinders, and the like. The container may also include a tamper-proof assemblage to prevent discreet access to the contents of the package. In addition, the container has deposited thereon a label that describes the contents of the container. The label may also include appropriate warnings.

Pharmaceutical formulations of the compounds of the present invention may be prepared for various routes and types of administration. For example, a compound of Formula I having the desired degree of purity may optionally be mixed with pharmaceutically acceptable diluents, carriers, excipients or stabilizers (Remington's Pharmaceutical Sciences (1980) 16th edition, Osol, A. Ed.), in the form of a lyophilized formulation, milled powder, or an aqueous solution. Formulation may be conducted by mixing at ambient temperature at the appropriate pH, and at the desired degree of purity, with physiologically acceptable carriers, i.e., carriers that are non-toxic to recipients at the dosages and concentrations employed. The pH of the formulation depends mainly on the particular use and the concentration of compound, but may range from about 3 to about 8. Formulation in an acetate buffer at pH 5 is a suitable embodiment.

The compound of this invention for use herein is preferably sterile. In particular, formulations to be used for in vivo administration must be sterile. Such sterilization is readily accomplished by filtration through sterile filtration membranes.

The compound ordinarily can be stored as a solid composition, a lyophilized formulation or as an aqueous solution.

The pharmaceutical compositions of the invention will be formulated, dosed and administered in a fashion, i.e., amounts, concentrations, schedules, course, vehicles and route of administration, consistent with good medical practice. Factors for consideration in this context
include the particular disorder being treated, the particular mammal being treated, the clinical condition of the individual patient, the cause of the disorder, the site of delivery of the agent, the method of administration, the scheduling of administration, and other factors known to medical practitioners. The "therapeutically effective amount" of the compound to be administered will be governed by such considerations, and is the minimum amount necessary to prevent, ameliorate, or treat the coagulation factor mediated disorder. Such amount is preferably below the amount that is toxic to the host or renders the host significantly more susceptible to bleeding. [00200] As a general proposition, the initial pharmaceutically effective amount of the inhibitor administered parenterally per dose will be in the range of about 0.01-100 mg/kg, namely about 0.1 to 20 mg/kg of patient body weight per day, with the typical initial range of compound used being 0.3 to 15 mg/kg/day. [00201] Acceptable diluents, carriers, excipients and stabilizers are nontoxic to recipients at the dosages and concentrations employed, and include buffers such as phosphate, citrate and other organic acids; antioxidants including ascorbic acid and methionine; preservatives (such as octadecyldimethylbenzyl ammonium chloride; hexamethonium chloride; benzalkonium chloride, benzethonium chloride; phenol, butyl or benzyl alcohol; alkyl parabens such as methyl or propyl paraben; catechol; resorcinol; cyclohexanol; 3-pentanol; and m-cresol); low molecular weight (less than about 10 residues) polypeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids such as glycine, glutamine, asparagine, histidine, arginine, or lysine; monosaccharides, disaccharides and other carbohydrates including glucose, mannose, or dextrins; chelating agents such as EDTA; sugars such as sucrose, mannitol, trehalose or sorbitol; salt-forming counter-ions such as sodium; metal complexes (e.g., Zn-protein complexes); and/or non-ionic surfactants such as TWEEN™, PLURONICS™ or polyethylene glycol (PEG). The active pharmaceutical ingredients may also be entrapped in microcapsules prepared, for example, by coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatin-microcapsules and poly-(methylmethacrylate) microcapsules, respectively, in colloidal drug delivery systems (for example, liposomes, albumin microspheres, microemulsions, nanoparticles and nanocapsules) or in macroemulsions. Such techniques are disclosed in Remington's Pharmaceutical Sciences 16th edition, Osol, A. Ed. (1980). [00202] Sustained-release preparations of compounds of Formula I and II may be prepared. Suitable examples of sustained-release preparations include semipermeable matrices of solid hydrophobic polymers containing a compound of Formula I or II, which matrices are in the form of shaped articles, e.g., films, or microcapsules. Examples of sustained-release matrices include polyesters, hydrogels (for example, poly(2-hydroxyethyl-methacrylate), or
poly(vinyl alcohol)), polylactides (U.S. Patent No. 3,773,919), copolymers of L-glutamic acid and gamma-ethyl-L-glutamate, non-degradable ethylene-vinyl acetate, degradable lactic acid-glycolic acid copolymers such as the LUPRON DEPOT™ (injectable microspheres composed of lactic acid-glycolic acid copolymer and leuprolide acetate) and poly-D-(−)-3-hydroxybutyric acid.

[00203] The formulations include those suitable for the administration routes detailed herein. The formulations may conveniently be presented in unit dosage form and may be prepared by any of the methods well known in the art of pharmacy. Techniques and formulations generally are found in Remington's Pharmaceutical Sciences (Mack Publishing Co., Easton, PA). Such methods include the step of bringing into association the active ingredient with the carrier which constitutes one or more accessory ingredients. In general the formulations are prepared by uniformly and intimately bringing into association the active ingredient with liquid carriers or finely divided solid carriers or both, and then, if necessary, shaping the product.

[00204] Formulations of a compound of Formula I or II suitable for oral administration may be prepared as discrete units such as pills, capsules, cachets or tablets each containing a predetermined amount of a compound of Formula I or II.

[00205] Compressed tablets may be prepared by compressing in a suitable machine the active ingredient in a free-flowing form such as a powder or granules, optionally mixed with a binder, lubricant, inert diluent, preservative, surface active or dispersing agent. Molded tablets may be made by molding in a suitable machine a mixture of the powdered active ingredient moistened with an inert liquid diluent. The tablets may optionally be coated or scored and optionally are formulated so as to provide slow or controlled release of the active ingredient therefrom.

[00206] Tablets, troches, lozenges, aqueous or oil suspensions, dispersible powders or granules, emulsions, hard or soft capsules, e.g., gelatin capsules, syrups or elixirs may be prepared for oral use. Formulations of compounds of Formula I and II intended for oral use may be prepared according to any method known to the art for the manufacture of pharmaceutical compositions and such compositions may contain one or more agents including sweetening agents, flavoring agents, coloring agents and preserving agents, in order to provide a palatable preparation. Tablets containing the active ingredient in admixture with non-toxic pharmaceutically acceptable excipient which are suitable for manufacture of tablets are acceptable. These excipients may be, for example, inert diluents, such as calcium or sodium carbonate, lactose, calcium or sodium phosphate; granulating and disintegrating agents, such as maize starch, or alginic acid; binding agents, such as starch, gelatin or acacia; and lubricating
agents, such as magnesium stearate, stearic acid or talc. Tablets may be uncoated or may be coated by known techniques including microencapsulation to delay disintegration and adsorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glycercyl monostearate or glycercyl distearate alone or with a wax may be employed.

[00207] For treatment of the eye or other external tissues, e.g., mouth and skin, the formulations are preferably applied as a topical ointment or cream containing the active ingredient(s) in an amount of, for example, 0.075 to 20% w/w. When formulated in an ointment, the active ingredients may be employed with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredients may be formulated in a cream with an oil-in-water cream base.

[00208] If desired, the aqueous phase of the cream base may include a polyhydric alcohol, i.e., an alcohol having two or more hydroxyl groups such as propylene glycol, butane 1,3-diol, mannitol, sorbitol, glycerol and polyethylene glycol (including PEG 400) and mixtures thereof. The topical formulations may desirably include a compound which enhances absorption or penetration of the active ingredient through the skin or other affected areas. Examples of such dermal penetration enhancers include dimethyl sulfoxide and related analogs.

[00209] The oily phase of the emulsions of this invention may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier, it desirably comprises a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make up the so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations. Emulsifiers and emulsion stabilizers suitable for use in the formulation of the invention include Tween® 60, Span® 80, cetostearyl alcohol, benzyl alcohol, myristyl alcohol, glycercyl mono-stearate and sodium lauryl sulfate.

[00210] Aqueous suspensions of Formula I or II compounds contain the active materials in admixture with excipients suitable for the manufacture of aqueous suspensions. Such excipients include a suspending agent, such as sodium carboxymethylcellulose, croscarmellose, povidone, methylcellulose, hydroxypropyl methylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia, and dispersing or wetting agents such as a naturally occurring phosphatide (e.g., lecithin), a condensation product of an alkylene oxide with a fatty acid (e.g., polyoxyethylene stearate), a condensation product of ethylene oxide with a long chain aliphatic alcohol (e.g., heptadecaethyleneoxycetanol), a condensation product of
ethylene oxide with a partial ester derived from a fatty acid and a hexitol anhydride (e.g.,
polyoxyethylene sorbitan monooleate). The aqueous suspension may also contain one or more
preservatives such as ethyl or n-propyl p-hydroxybenzoate, one or more coloring agents, one or
more flavoring agents and one or more sweetening agents, such as sucrose or saccharin.

The pharmaceutical compositions of compounds of Formula I may be in the form
of a sterile injectable preparation, such as a sterile injectable aqueous or oleaginous suspension.
This suspension may be formulated according to the known art using those suitable dispersing or
wetting agents and suspending agents which have been mentioned above. The sterile injectable
preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally
acceptable diluent or solvent, such as a solution in 1,3-butanediol or prepared as a lyophilized
powder. Among the acceptable vehicles and solvents that may be employed are water, Ringer's
solution and isotonic sodium chloride solution. In addition, sterile fixed oils may conventionally
be employed as a solvent or suspending medium. For this purpose any bland fixed oil may be
employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid
may likewise be used in the preparation of injectables.

The amount of active ingredient that may be combined with the carrier material
to produce a single dosage form will vary depending upon the host treated and the particular
mode of administration. For example, a time-release formulation intended for oral
administration to humans may contain approximately 1 to 1000 mg of active material
compounded with an appropriate and convenient amount of carrier material which may vary
from about 5 to about 95% of the total compositions (weight:weight). The pharmaceutical
composition can be prepared to provide easily measurable amounts for administration. For
example, an aqueous solution intended for intravenous infusion may contain from about 3 to 500
μg of the active ingredient per milliliter of solution in order that infusion of a suitable volume at
a rate of about 30 mL/hr can occur.

Formulations suitable for parenteral administration include aqueous and non-
aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and
solutes which render the formulation isotonic with the blood of the intended recipient; and
aqueous and non-aqueous sterile suspensions which may include suspending agents and
thickening agents.

Formulations suitable for topical administration to the eye also include eye drops
wherein the active ingredient is dissolved or suspended in a suitable carrier, especially an
aqueous solvent for the active ingredient. The active ingredient is preferably present in such
formulations in a concentration of about 0.5 to 20% w/w, for example about 0.5 to 10% w/w, for
example about 1.5% w/w.
Formulations suitable for topical administration in the mouth include lozenges comprising the active ingredient in a flavored basis, usually sucrose and acacia or tragacanth; pastilles comprising the active ingredient in an inert basis such as gelatin and glycerin, or sucrose and acacia; and mouthwashes comprising the active ingredient in a suitable liquid carrier.

Formulations for rectal administration may be presented as a suppository with a suitable base comprising for example cocoa butter or a salicylate.

Formulations suitable for intrapulmonary or nasal administration have a particle size for example in the range of 0.1 to 500 microns (including particle sizes in a range between 0.1 and 500 microns in increments microns such as 0.5, 1, 30 microns, 35 microns, etc.), which is administered by rapid inhalation through the nasal passage or by inhalation through the mouth so as to reach the alveolar sacs. Suitable formulations include aqueous or oily solutions of the active ingredient. Formulations suitable for aerosol or dry powder administration may be prepared according to conventional methods and may be delivered with other therapeutic agents such as compounds heretofore used in the treatment or prophylaxis disorders as described below.

Formulations suitable for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams or spray formulations containing in addition to the active ingredient such carriers as are known in the art to be appropriate.

The formulations may be packaged in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water, for injection immediately prior to use. Extemporaneous injection solutions and suspensions are prepared from sterile powders, granules and tablets of the kind previously described. Preferred unit dosage formulations are those containing a daily dose or unit daily sub-dose, as herein above recited, or an appropriate fraction thereof, of the active ingredient.

The invention further provides veterinary compositions comprising at least one active ingredient as above defined together with a veterinary carrier therefore. Veterinary carriers are materials useful for the purpose of administering the composition and may be solid, liquid or gaseous materials which are otherwise inert or acceptable in the veterinary art and are compatible with the active ingredient. These veterinary compositions may be administered parenterally, orally or by any other desired route.

COMBINATION THERAPY

The compounds of Formula I and II may be employed alone or in combination
with other therapeutic agents for the treatment of a disease or disorder described herein, such as a hyperproliferative disorder (e.g., cancer). In certain embodiments, a compound of Formula I or II is combined in a pharmaceutical combination formulation, or dosing regimen as combination therapy, with a second compound that has anti-hyperproliferative properties or that is useful for treating a hyperproliferative disorder (e.g., cancer). The second compound of the pharmaceutical combination formulation or dosing regimen preferably has complementary activities to the compound of Formula I such that they do not adversely affect each other. Such compounds are suitably present in combination in amounts that are effective for the purpose intended. In one embodiment, a composition of this invention comprises a compound of Formula I or II, in combination with a chemotherapeutic agent such as described herein.

[00223] The combination therapy may be administered as a simultaneous or sequential regimen. When administered sequentially, the combination may be administered in two or more administrations. The combined administration includes coadministration, using separate formulations or a single pharmaceutical formulation, and consecutive administration in either order, wherein preferably there is a time period while both (or all) active agents simultaneously exert their biological activities.

[00224] Suitable dosages for any of the above coadministered agents are those presently used and may be lowered due to the combined action (synergy) of the newly identified agent and other chemotherapeutic agents or treatments.

[00225] The combination therapy may provide "synergy" and prove "synergistic", i.e., the effect achieved when the active ingredients used together is greater than the sum of the effects that results from using the compounds separately. A synergistic effect may be attained when the active ingredients are: (1) co-formulated and administered or delivered simultaneously in a combined, unit dosage formulation; (2) delivered by alternation or in parallel as separate formulations; or (3) by some other regimen. When delivered in alternation therapy, a synergistic effect may be attained when the compounds are administered or delivered sequentially, e.g., by different injections in separate syringes, separate pills or capsules, or separate infusions. In general, during alternation therapy, an effective dosage of each active ingredient is administered sequentially, i.e., serially, whereas in combination therapy, effective dosages of two or more active ingredients are administered together.

[00226] In a particular embodiment of anti-cancer therapy, a compound of Formula I, or a stereoisomer, geometric isomer, tautomer, solvate, metabolite, or pharmaceutically acceptable salt or prodrug thereof, may be combined with other chemotherapeutic, hormonal or antibody agents such as those described herein, as well as combined with surgical therapy and radiotherapy. Combination therapies according to the present invention thus comprise the
administration of at least one compound of Formula I, or a stereoisomer, geometric isomer, tautomer, solvate, metabolite, or pharmaceutically acceptable salt or prodrug thereof, and the use of at least one other cancer treatment method. The amounts of the compound(s) of Formula I and the other pharmaceutically active chemotherapeutic agent(s) and the relative timings of administration will be selected in order to achieve the desired combined therapeutic effect.

[00227] METABOLITES OF COMPOUNDS OF FORMULA I and II

[00228] Also falling within the scope of this invention are the in vivo metabolic products of Formula I and II described herein. Such products may result for example from the oxidation, reduction, hydrolysis, amidation, deamidation, esterification, deesterification, enzymatic cleavage, and the like, of the administered compound. Accordingly, the invention includes metabolites of compounds of Formula I and II, including compounds produced by a process comprising contacting a compound of this invention with a mammal for a period of time sufficient to yield a metabolic product thereof.

[00229] Metabolite products typically are identified by preparing a radiolabeled (e.g., $^{14}$C or $^{3}$H) isotope of a compound of the invention, administering it parenterally in a detectable dose (e.g., greater than about 0.5 mg/kg) to an animal such as rat, mouse, guinea pig, monkey, or to man, allowing sufficient time for metabolism to occur (typically about 30 seconds to 30 hours) and isolating its conversion products from the urine, blood or other biological samples. These products are easily isolated since they are labeled (others are isolated by the use of antibodies capable of binding epitopes surviving in the metabolite). The metabolite structures are determined in conventional fashion, e.g., by MS, LC/MS or NMR analysis. In general, analysis of metabolites is done in the same way as conventional drug metabolism studies well known to those skilled in the art. The metabolite products, so long as they are not otherwise found in vivo, may be useful in diagnostic assays for therapeutic dosing of the compounds of the invention.

[00230] ARTICLES OF MANUFACTURE

[00231] In another embodiment of the invention, an article of manufacture, or "kit", containing materials useful for the treatment of the diseases and disorders described above is provided. The kit comprises a container comprising a compound of Formula I or II. The kit may further comprise a label or package insert, on or associated with the container. The term "package insert" is used to refer to instructions customarily included in commercial packages of therapeutic products, that contain information about the indications, usage, dosage, administration, contraindications and/or warnings concerning the use of such therapeutic products. Suitable containers include, for example, bottles, vials, syringes, blister pack, etc. The container may be formed from a variety of materials such as glass or plastic. The container
may hold a compound of Formula I or II or a formulation thereof which is effective for treating the condition and may have a sterile access port (for example, the container may be an intravenous solution bag or a vial having a stopper pierceable by a hypodermic injection needle). At least one active agent in the composition is a compound of Formula I or II. The label or package insert indicates that the composition is used for treating the condition of choice, such as cancer. In addition, the label or package insert may indicate that the patient to be treated is one having a disorder such as a hyperproliferative disorder, neurodegeneration, cardiac hypertrophy, pain, migraine or a neurotraumatic disease or event. In one embodiment, the label or package inserts indicates that the composition comprising a compound of Formula I or II can be used to treat a disorder resulting from abnormal cell growth. The label or package insert may also indicate that the composition can be used to treat other disorders. Alternatively, or additionally, the article of manufacture may further comprise a second container comprising a pharmaceutically acceptable buffer, such as bacteriostatic water for injection (BWFI), phosphate-buffered saline, Ringer's solution and dextrose solution. It may further include other materials desirable from a commercial and user standpoint, including other buffers, diluents, filters, needles, and syringes.

[00232] The kit may further comprise directions for the administration of the compound of Formula I or II and, if present, the second pharmaceutical formulation. For example, if the kit comprises a first composition comprising a compound of Formula I or II, and a second pharmaceutical formulation, the kit may further comprise directions for the simultaneous, sequential or separate administration of the first and second pharmaceutical compositions to a patient in need thereof.

[00233] In another embodiment, the kits are suitable for the delivery of solid oral forms of a compound of Formula I or II, such as tablets or capsules. Such a kit preferably includes a number of unit dosages. Such kits can include a card having the dosages oriented in the order of their intended use. An example of such a kit is a "blister pack". Blister packs are well known in the packaging industry and are widely used for packaging pharmaceutical unit dosage forms. If desired, a memory aid can be provided, for example in the form of numbers, letters, or other markings or with a calendar insert, designating the days in the treatment schedule in which the dosages can be administered.

[00234] According to one embodiment, a kit may comprise (a) a first container with a compound of Formula I or II contained therein; and optionally (b) a second container with a second pharmaceutical formulation contained therein, wherein the second pharmaceutical formulation comprises a second compound with anti-hyperproliferative activity. Alternatively, or additionally, the kit may further comprise a third container comprising a pharmaceutically-
acceptable buffer, such as bacteriostatic water for injection (BWFI), phosphate-buffered saline, Ringer's solution and dextrose solution. It may further include other materials desirable from a commercial and user standpoint, including other buffers, diluents, filters, needles, and syringes. In certain other embodiments wherein the kit comprises a composition of Formula I and a second therapeutic agent, the kit may comprise a container for containing the separate compositions such as a divided bottle or a divided foil packet, however, the separate compositions may also be contained within a single, undivided container. Typically, the kit comprises directions for the administration of the separate components. The kit form is particularly advantageous when the separate components are preferably administered in different dosage forms (e.g., oral and parenteral), are administered at different dosage intervals, or when titration of the individual components of the combination is desired by the prescribing physician.

**GENERAL PREPARATIVE PROCEDURES**

**General Procedure A**

**General Procedure B**

Benzoxepin carboxylic acid intermediates B-I are converted to the acid chloride B-2 and reacted with primary or secondary amines with triethylamine, DMAP, and solvent such
as dichloromethane. Reaction with a primary amine may be followed by N-alkylation, for example with methyl iodide and sodium hydride, to generate 4,5-dihydrobenzo[b]thieno[2,3-d]oxepine-2-carboxamide B-3.

[00241] For example, to a suspension of carboxylic acid (0.4 mmol) in anhydrous dichloromethane, is added oxalyl chloride (0.7 mmol) and one drop of dimethyl formamide. After 30 minutes, concentrate in-vacuo. Residue is dissolved in acetonitrile, and potassium carbonate (0.9 mmol) and an amine, e.g. aniline (0.48 mmol) are added. Reaction mixture is stirred overnight at room temperature before diluting with water and ethylacetate. Organic phase is dried (MgSO\(_4\)) and concentrated in-vacuo.

[00242] Alternatively, other active esters of benzoxepin carboxylic acid intermediates B-I can be formed as anhydrides, acyl imidazolides, acyl azides, and NHS esters to react with amines. Also, benzoxepin carboxylic acid intermediates B-I can be coupled with amines by in situ formation of active ester intermediates under the broad array of known peptide coupling reagents and methodology.

[00243] For example, to a solution of the carboxylic acid (1 eq) in DMF (6 mL) is added the amine (1.3 eq), HATU (1.3 eq) and diisopropylethyl amine (1.3 eq + 1.3 eq for each HCl salt of the amine) and the reaction stirred at room temperature for 16 h. The mixture is partitioned between ethyl acetate and water. The organic layer was washed with brine (3 x), dried (MgSO\(_4\)), reduced in vacuo and purified on silica to give the final amide.

[00244] General Procedure C
C-I are carbonylated with carbon monoxide under high pressure with palladium catalysis, such as Pd(OAc)$_2$, and an alcohol, such as methanol to give the carboxamide intermediate C-2. Saponification with lithium hydroxide, sodium hydroxide or other aqueous base to the 8-carboxylic acid intermediate, followed by coupling of a primary or secondary amine with a coupling reagent, such as HATU or DCC gives the 9-carboxamide intermediate C-3.

Alternatively, intermediate C-3 may be prepared directly from bromo intermediate C-I by aminocarbonylation, following the procedures of Wannberg et al (2003) J. Org. Chem. 68:5750-5753.

General Procedure D

General Procedure E
8-Bromo-4H-thieno[3,2-c]chromene-2-carboxamide intermediates E-1 are formylated with butyl lithium and dimethylformamide (DMF) to give E-2 which is reductively aminated with a hydride such as sodium acetoxyborohydride and a primary or secondary amine (HNR<sup>10</sup>R<sup>11</sup>).

**General Procedure A-bp**

Benzopyran intermediates A-lbp can be selectively brominated with N-bromosuccinimide (NBS) in DMF to give 8-bromo-4H-thieno[3,2-c]chromene-2-carboxylate esters A-2bp.

**General Procedure B-bp**
Benzopyran carboxylic acid intermediates B-lbp are converted to the acid chloride B-2bp and reacted with primary or secondary amines with triethylamine, DMAP, and solvent such as dichloromethane. Reaction with a primary amine may be followed by N-alkylation, for example with methyl iodide and sodium hydride, to generate carboxamide B-3bp.

General Procedure C-bp

8-Bromo-4H-thieno[3,2-c]chromene-2-carboxamide intermediates C-lbp are carbonylated with carbon monoxide under high pressure with palladium catalysis, such as Pd(OAc)$_2$, and an alcohol, such as methanol to give the 8-carboxylate ester 4H-thieno[3,2-c]chromene-2-carboxamide intermediate C-2bp. Saponification with lithium hydroxide, sodium hydroxide or other aqueous base to the 8-carboxylic acid intermediate, followed by coupling of a primary or secondary amine with a coupling reagent, such as HATU or DCC gives the 8-carboxamide 4H-thieno[3,2-c]chromene-2-carboxamide intermediate C-3bp.
Alternatively, intermediate C-3bp may be prepared directly from bromo intermediate C-1bp by aminocarbonylation, following the procedures of Wannberg et al (2003) J. Org. Chem. 68:5750-5753.

General Procedure D-bp

**EXAMPLES**

The chemical reactions described in the Examples may be readily adapted to prepare a number of other PBK inhibitors of the invention, and alternative methods for preparing the compounds of this invention are deemed to be within the scope of this invention. For example, the synthesis of non-exemplified compounds according to the invention may be successfully performed by modifications apparent to those skilled in the art, e.g., by appropriately protecting interfering groups, by utilizing other suitable reagents known in the art other than those described, and/or by making routine modifications of reaction conditions. Alternatively, other reactions disclosed herein or known in the art will be recognized as having applicability for preparing other compounds of the invention.

In the Examples described below, unless otherwise indicated all temperatures are set forth in degrees Celsius. Reagents were purchased from commercial suppliers such as Sigma Aldrich Chemical Company, and were used without further purification unless otherwise indicated. The reactions set forth below were conducted generally under a positive pressure of nitrogen or argon or with a drying tube (unless otherwise stated) in anhydrous solvents, and the reaction flasks were typically fitted with rubber septa for the introduction of substrates and reagents via syringe. Glassware was oven dried and/or heat dried. Column chromatography was conducted on a Biotage system (Manufacturer: Dyax Corporation) having a silica gel column or on a silica SEP PAK\textregistered cartrige (Waters). \textsuperscript{1}H NMR spectra were obtained at 400 MHz in deuterated CDCl\textsubscript{3}, d\textsubscript{6}-DMSO, CH\textsubscript{3}OD or d\textsubscript{6}-acetone solutions (reported in ppm), using chloroform as the reference standard (7.25 ppm). When peak multiplicities are reported, the following abbreviations are used: s (singlet), d (doublet), t (triplet), m (multiplet), br (broadened), dd (doublet of doublets), dt (doublet of triplets). Coupling constants, when given, are reported in Hertz (Hz).

[00910] Example 275 pi 1Qα (alpha) PI3K Binding Assay

[00911] Binding Assays: Initial polarization experiments were performed on an Analyst HT 96-384 (Molecular Devices Corp, Sunnyvale, CA.). Samples for fluorescence polarization affinity measurements were prepared by addition of 1:3 serial dilutions of pi 10 alpha PI3K (Upstate Cell Signaling Solutions, Charlottesville, VA) starting at a final concentration of 20μg/mL in polarization buffer (10 mM tris pH 7.5, 50 mM NaCl, 4mM MgCl_2, 0.05%Chaps, and 1 mM DTT) to 10mM PIP_2 (Echelon-Inc, Salt Lake City, UT) final concentration. After an incubation time of 30 minutes at room temperature, the reactions were stopped by the addition of GRP-I and PIP3-TAMRA probe (Echelon-Inc, Salt Lake City, UT) 100 nM and 5 nM final concentrations respectively. Read with standard cut-off filters for the rhodamine fluorophore (λex = 530 nm; λem = 590 nm) in 384-well black low volume Proxiplates (PerkinElmer, Wellesley, MA.) Fluorescence polarization values were plotted as a function of the protein concentration, and the EC_{50} values were obtained by fitting the data to a 4-parameter
equation using KaleidaGraph software (Synergy software, Reading, PA). This experiment also establishes the appropriate protein concentration to use in subsequent competition experiments with inhibitors.

Inhibitor IC$_{50}$ values were determined by addition of the 0.04 mg/mL p 10 alpha PI3K (final concentration) combined with PIP$_2$ (10mM final concentration) to wells containing 1:3 serial dilutions of the antagonists in a final concentration of 25mM ATP (Cell Signaling Technology, Inc., Danvers, MA) in the polarization buffer. After an incubation time of 30 minutes at room temperature, the reactions were stopped by the addition of GRP-I and PIP3-TAMRA probe (Echelon-Inc, Salt Lake City, UT.) 100 nM and 5 nM final concentrations respectively. Read with standard cut-off filters for the rhodamine fluorophore ($\lambda_{em} = 590$ nm; $\lambda_{ex} = 530$ nm) in 384-well black low volume proxi plates (PerkinElmer, Wellesley, MA.) Fluorescence polarization values were plotted as a function of the antagonist concentration, and the IC$_{50}$ values were obtained by fitting the data to a 4-parameter equation in Assay Explorer software (MDL, San Ramon, CA.).

Alternatively, inhibition of PI3K was determined in a radiometric assay using purified, recombinant enzyme and ATP at a concentration of 1uM. The Formula I compound was serially diluted in 100% DMSO. The kinase reaction was incubated for 1 hr at room temperature, and the reaction was terminated by the addition of PBS. IC$_{50}$ values were subsequently determined using sigmoidal dose-response curve fit (variable slope).

**Example 276.** In vitro cell proliferation assay

Efficacy of Formula I compounds were measured by a cell proliferation assay employing the following protocol (Promega Corp. Technical Bulletin TB288; Mendoza et al (2002) Cancer Res. 62:5485-5488):

1. An aliquot of 100 µl of cell culture containing about 10$^4$ cells (PC3, Detroit562, or MDAMB361.1) in medium was deposited in each well of a 384-well, opaque-walled plate.

2. Control wells were prepared containing medium and without cells.

3. The compound was added to the experimental wells and incubated for 3-5 days.

4. The plates were equilibrated to room temperature for approximately 30 minutes.

5. A volume of CellTiter-Glo Reagent equal to the volume of cell culture medium present in each well was added.

6. The contents were mixed for 2 minutes on an orbital shaker to induce cell lysis.
7. The plate was incubated at room temperature for 10 minutes to stabilize the luminescence signal.

8. Luminescence was recorded and reported in graphs as RLU = relative luminescence units.

Alternatively, cells were seeded at optimal density in a 96 well plate and incubated for 4 days in the presence of test compound. Alamar Blue™ was subsequently added to the assay medium, and cells were incubated for 6 hr before reading at 544 nm excitation, 590 nm emission. EC<sub>50</sub> values were calculated using a sigmoidal dose response curve fit.

Example 277  Caco-2 Permeability

Caco-2 cells are seeded onto Millipore Multiscreen plates at 1 x 10<sup>5</sup> cells/cm<sup>2</sup>, and cultured for 20 days. Assessment of compound permeability is subsequently conducted. The compounds are applied to the apical surface (A) of cell monolayers and compound permeation into the basolateral (B) compartment was measured. This is performed in the reverse direction (B-A) to investigate active transport. A permeability coefficient value, P<sub>app</sub>, for each compound, a measure of the rate of permeation of the compound across the membrane, is calculated. Compounds are grouped into low (P<sub>app</sub> <\= 1.0 x 10<sup>6</sup>cm/s) or high (P<sub>app</sub> >\= 1.0 x 10<sup>6</sup>cm/s) absorption potential based on comparison with control compounds with established human absorption.

For assessment of a compound's ability to undergo active efflux, the ratio of basolateral (B) to apical (A) transport compared with A to B was determined. Values of B-A/A-B >\= 1.0 indicate the occurrence of active cellular efflux.

Example 278  Hepatocyte Clearance

Suspensions of cryopreserved human hepatocytes are used. Incubations are performed at compound concentration of 1mM or 3µM at a cell density of 0.5 x 10<sup>6</sup> viable cells/mL. The final DMSO concentration in the incubation is about 0.25%. Control incubations are also performed in the absence of cells to reveal any non-enzymatic degradation. Duplicate samples (50µL) are removed from the incubation mixture at 0, 5, 10, 20, 40 and 60 minutes (control sample at 60 minutes only) and added to methanol containing internal standard (100µL) - to terminate the reaction. Tolbutamide, 7-hydroxycoumarin, and testosterone may be used as control compounds. Samples are centrifuged and the supernatants at each time point pooled for analysis by LC-MSMS. From a plot of In peak area ratio (parent compound peak area / internal standard peak area) against time, intrinsic clearance (CL<sub>int</sub>) is calculated as follows: CL<sub>int</sub> (µL/min/million cells) = V x k, where k is the elimination rate constant, obtained from the gradient of ln concentration plotted against time; V is a volume term derived from the incubation volume and is expressed as uL 10<sup>6</sup> cells<sup>-1</sup>.

Example 279 Cytochrome P450 Inhibition

Formula I compounds may be screened against CYP450 targets (1A2, 2C9, 2C19, 2D6, 3A4) at about 10 concentrations in duplicate, with a top concentration of about 100µM. Standard inhibitors (furafylline, sulfaphenazole, tranylcyromine, quinidine, ketoconazole) may be used as controls. Plates may be read using a BMG LabTechnologies PolarStar in fluorescence mode.

Example 280 Cytochrome P450 Induction

Freshly isolated human hepatocytes from a single donor may be cultured for about 48 hr prior to addition of Formula I compound at three concentrations and incubated for 72 hr. Probe substrates for CYP3A4 and CYP1A2 are added for 30 minutes and 1 hr before the end of the incubation. At 72 hr, cells and media are removed and the extent of metabolism of each probe substrate quantified by LC-MS/MS. The experiment is controlled by using inducers of the individual P450s incubated at one concentration in triplicate.

Example 281 Plasma Protein Binding

Solutions of Formula I compound (5um, 0.5% final DMSO concentration) are prepared in buffer and 10% plasma (v/v in buffer). A 96 well HT dialysis plate is assembled so that each well is divided in two by a semi-permeable cellulose membrane. The buffer solution is added to one side of the membrane and the plasma solution to the other side; incubations are then conducted at 37 °C over 2 hr in triplicate. The cells are subsequently emptied, and the solutions for each batch of compounds are combined into two groups (plasma-free and plasma-containing) then analyzed by LC-MSMS using two sets of calibration standards for plasma-free (6 points) and plasma-containing solutions (7 points). The fraction unbound value for the compound is calculated.

Example 282 hERG channel blockage

Formula I compounds are evaluated for ability to modulate rubidium efflux from HEK-294 cells stably expressing hERG potassium channels using established flux methodology. Cells are prepared in medium containing RbCl, plated into 96-well plates and grown overnight to form monolayers. The efflux experiment is initiated by aspirating the media and washing each well with 3 x 100µL of pre-incubation buffer (containing low [K+]) at room temperature. Following the final aspiration, 50 µL of working stock (2x) compound is added to each well and incubated at room temperature for 10 minutes. Stimulation buffer 50µL (containing high [K+]) is then added to each well giving the final test compound concentrations. Cell plates are then incubated at room temperature for a further 10 minutes. Supernatant 80µL from each well is then transferred to equivalent wells of a 96-well plate and analyzed via atomic emission.
spectroscopy. The compound is screened as lOpt duplicate IC\textsubscript{50} curves, n=2, from a top concentration of 100 µM.

[00938] **Example 283** In Vivo Tumor Xenograft

[00939] Animals suitable for transgenic experiments can be obtained from standard commercial sources. Groups of Taconic nude mice (were implanted subcutaneously in the hind flank with MDA-MB-361.1 (PI3K mutant) breast cancer cells. Mouse xenografts were dosed daily for 21 days with drug or vehicle. Tumor sizes were recorded twice weekly over the course of the study. Mouse body weights were also recorded twice weekly, and the mice were observed regularly. Tumor volume was measured in two dimensions (length and width) using Ultra Cal-IV calipers (Model 54-10-111; Fred V. Fowler Co., Inc.; Newton, MA) and analyzed using Excel v.1 1.2 (Microsoft Corporation; Redmond, WA). Tumor inhibition graphs were plotted using KaleidaGraph, Version 3.6 (Synergy Software; Reading, PA). The tumor volume was calculated with formula: Tumor size (mm\textsuperscript{3}) = (longer measurement \times shorter measurement\textsuperscript{2}) \times 0.5

[00940] Animal body weights were measured using an Adventurerera Pro AV812 scale (Ohaus Corporation; Pine Brook, NJ). Graphs were generated using KaleidaGraph Version 3.6. Percent weight change was calculated using formula: Group percent weight change = (1 - (initial weight / new weight)) \times 100.

[00941] Mice whose tumor volume exceeded 2000 mm\textsuperscript{3} or whose body weight loss was > 20% of their starting weight were promptly euthanized according to regulatory guidance.

[00942] The percent tumor growth inhibition (% INH) at the end of study (EOS) was calculated using formula: % INH = 100 x (EOS mean volume of tumors in animals given vehicle - EOS mean volume of tumors in animals given the drug)/EOS mean volume of tumors in animals given vehicle.

[00943] Tumor incidence (TI) was determined based on the number of measurable tumors remaining in each group at the end of the study. A partial response (PR) was defined as a > 50% but ≤ 100% reduction in tumor volume, compared with the starting tumor volume, observed on any day of the study. A complete response (CR) was defined as a 100% reduction in tumor volume, compared with the initial tumor volume, observed on any day of the study. Data were analyzed and p-values were determined using the Dunnett's test with JMP statistical software, version 5.1.2 (SAS Institute; Cary, NC). Individual tumor volumes at end of study and mean tumor volume ± SEM values were calculated using JMP statistical software, version 5.1.2. Body weight data were graphed based on the mean percentage of change from initial body weights ±SEM.

filtered, and purified by preparative RP-HPLC to give 98 mg of 171bp as the TFA salt. Yield = 40% of theoretical. MS: (ESI+) = 341.4

[001202] N-(2-fluororophenyl)-7-fluoro-4H-thieno[3,2-c]chromene-2-carboxamide (0.200 g, 0.582 mmol) was taken into dichloromethane (DCM) and placed under nitrogen (N2). Cesium carbonate was added as a solid and stirred into solution for several minutes. This solution was cooled (ice/H2O) and methyl iodide (MeI) was added slowly dropwise. The cooling bath was immediately removed and reaction was monitored by LC/MS for loss of starting material. The completed reaction was diluted with EtOAc and the organic phase was washed with water x 2, followed by saline x 1, then dried (MgSO4). The dried organic phase was concentrated in vacuo and the resulting residue was taken into DMF at a concentration of 100 mg/mL, and purified by preparative RP-HPLC to give 172bp. MS: Yield = 25% of theoretical. (ESI+) = 358.4

[001204] Sodium borohydride (8 mg, 0.2 mmol) was added to a solution of N-(2-chlorophenyl)-N-methyl-4-oxo-4,5-dihydrobenzo[b]thiieno[2,3-d]oxepine-2-carboxamide 193bzO (38 mg, 0.1 mmol) in 2 ml of methanol. The mixture was stirred for 30 min, poured into 4 ml of water and extracted with 3 ml of ethylacetate. The ethylacetate layer was washed with water, brine and dried over magnesium sulfate. The crude product was purified by normal phase column chromatography using dichloromethane/ethylacetate mobile phase (ethylacetate gradient 0-20%) to yield 191bzOH (0.022 g, 57%). MS: (ESI+) MH+ = 386.1

To 4H-thieno[3,2-c]chromene-2-carboxylic acid (1.65 g, 7.10 mmol) in THF (70 mL) at -78 °C was added a 1.5 M solution of tert-butyllithium in pentane (15 mL). The resulting solution stirred 1 hr at -78 °C. N-fluoro-N-(phenylsulfonyl)benzenesulfonamide (7.2 g, 23 mmol) was added and the reaction warmed to room temperature over 2 hr. The reaction was quenched by the addition of 1 M HCl to effect pH 3. The aqueous layer was extracted with CH$_2$Cl$_2$. The combined organics were dried over Na$_2$SO$_4$, filtered, and concentrated in vacuo to yield 3-fluoro-4H-thieno[3,2-c]chromene-2-carboxylic acid, which contained less than 40% 4H-thieno[3,2-c]chromene-2-carboxylic acid, which was utilized in the next step without purification (1.0 g). MS (Ql) 249 (M)+

To 3-fluoro-4H-thieno[3,2-c]chromene-2-carboxylic acid (1.0 g, >60% purity) in CH$_2$Cl$_2$ (17 mL) was added thionyl chloride (0.6 mL) followed by a few drops of DMF. The reaction was heated to reflux for several hours. The crude reaction mixture was concentrated in vacuo. To the residue was added CH$_2$Cl$_2$ (50 mL), 2-chloroaniline (1.1 mL), and a catalytic amount of 4-dimethylaminopyridine. Next, pyridine (5 mL) and the reaction stirred at room temperature. After 4 hr the reaction was concentrated in vacuo and partially purified by silica gel chromatography (hexane/ethylacetate as eluent) to provide N-(2-chlorophenyl)-3-fluoro-4H-thieno[3,2-c]chromene-2-carboxamide along with an unidentified by-product. MS (Ql) 360 (M)+

To N-(2-chlorophenyl)-3-fluoro-4H-thieno[3,2-c]chromene-2-carboxamide in DMF was added sodium hydride (0.16 g) then methyl iodide (0.37 mL). The resulting solution stirred 45 min at room temperature. The reaction was quenched by pouring into ice water. The aqueous layer was extracted with EtOAc. The combined organics were washed with brine, dried over Na$_2$SO$_4$, filtered, and concentrated in vacuo. After partial purification by silica gel chromatography (CH$_2$Cl$_2$/EtOAc) the product was purified by reverse phase HPLC to afford 192bp (18 mg). MS (Ql) 374 (M)+
