(57) Abstract: The present invention includes a method and system for separating oil from water and particulate contaminants from a oil/water/solid mixture, comprising a solid removal system for removing small, medium and large solids from a oil/water/solid mixture to form a oil and water stream and a membrane contactor system for separating the oil from the water in the oil and water stream.
NON-DISPERSIVE OIL RECOVERY FROM OIL INDUSTRY LIQUID SOURCES

TECHNICAL FIELD OF THE INVENTION

The present invention relates in general to the industry of oil recovery and reclamation from oil industry liquid sources, and more particularly, to systems and methods for the recovery of oil from mixed liquid sources that may contain solids.

BACKGROUND OF THE INVENTION

Without limiting the scope of the invention, its background is described in connection with improved oil recovery and reclamation.

United States Patent No. 3,956,112, issued to Lee, et al., is directed to a membrane solvent extraction. Briefly, this patent is said to describe a membrane solvent extraction system that is used to separate a dissolved solute from one liquid referred to as the carrier into a second liquid which is immiscible with the carrier and is referred to as the solvent. Therefore the hollow fiber membrane is used to extract a solute through a solvent swollen membrane from one solvent liquid phase to the extracting solvent liquid with direct contact between the liquid phases only within the porous walls.

The membrane extraction method has potential advantages over conventional solvent extraction in that it does not require a density difference and provides a large amount of contact area. The membrane extraction contactor may be applied to molecular diffusion based mass transfer separation processes as the mechanism for separation, purification, pollutant removal and recovery processes. This reference relies on liquid extraction, as the solvent swells the membrane filling the pores and providing a diffusional process to extract a dissolved solute from an immiscible liquid carrier.

United States Patent No. 5,252,220, issued to Coughlin, et al., is directed to the preparation of analytical samples by liquid-liquid extraction using microporous hollow-fiber membranes. Briefly, this patent is said to teach a method and apparatus for accomplishing improved liquid-liquid extraction employing microporous hollow-fiber membranes. A number of modes of liquid-liquid extraction are possible according to the invention. As with the prior art, this patent relies on the interaction between two liquids, one of the contact side and one on the other side of the membrane for separation and concentration driving force diffusion of a dissolve solute across the liquid-liquid interface immobilized in the pore.
United States Patent No. 6,436,290, issued to Glassford is directed to a method and apparatus for separating mixtures of organic and aqueous liquid phases. Briefly, this patent is said to include a method and apparatus for separating a mixture containing an aqueous liquid and an immiscible organic phase using microporous hollow fibers. Such mixtures are separated into a substantially organic-free aqueous phase and a substantially aqueous-free organic phase. The mixture is pressurized in a controlled low shear manner to minimize emulsification as it is contacted with the fibers. Productivity is said to be enhanced by separating as a third product stream, a further organic phase containing only small amounts of an aqueous phase, which for some applications can usefully be combined with the substantially aqueous-free organic phase.

United States Patent No. 7,186,344, issued to Hughes is directed to a membrane-based fluid treatment system. Briefly, this patent teaches a process for removing soluble and insoluble inorganic, organic, and microbiological contaminants from a fluid stream employing a pretreatment module, a post-treatment module, a recycle stream module or any combination thereof, and a membrane module. The process reduces the problems associated with membrane fouling and increases contaminant removal capacity.

United States Patent No. 8,128,827, issued to Gallo, et al., teaches a modular oil-based sludge separation and treatment system. Briefly, this patent discloses a method of recovering oil from oil-based sludge including the steps of homogenizing an oil-rich phase, a water-rich phase, and a solids-rich phase of an oil-based sludge, removing particulates from the oil-based sludge as the sludge traverses a shaker screen, heating the sludge, injecting a chemical into the heated sludge and mixing the chemical with the heated sludge, separating the phases of the chemically-treated sludge into a solids component stream, a water component stream, a first oil component stream, and a gas component stream, removing solids from the first oil component stream with a decanting centrifuge to form a second oil component stream, and removing water and solids from the second oil component stream with a disk stack centrifuge.

United States Patent Application Publication No. 2010/0173806, filed by Fan, et al., is directed to the extraction of hydrocarbons from hydrocarbon-containing materials and includes a method of extracting hydrocarbon-containing organic matter from a hydrocarbon-containing material includes the steps of providing a first liquid comprising a turpentine liquid; contacting the hydrocarbon-containing material with the turpentine liquid to form an extraction mixture; extracting the hydrocarbon material into the turpentine liquid; and separating the extracted hydrocarbon material from a residual material not extracted.
United States Patent Application Publication No. 2005/0098504 filed by Manz, et al., is directed to an oil and gas well fracturing (frac) water treatment process. Briefly, a novel process for treating and removing undesirable impurities from oil and gas well fracturing fluid is disclosed. For example, a method for treating fracturing water is taught comprising: (a) passing contaminated fracturing water containing solids and liquid through a mechanical separator to remove solids from the liquid; (b) treating the fracturing water liquid with an alkaline agent to increase the pH of the liquid to a level of above 9; (c) adding a coagulant to the fracturing water to form an agglomerate and separating the agglomerate from the fracturing water; (d) reducing the pH of the fracturing water of step (c) to a level of less than about 5.5; and (e) adding an oxidizing agent to the fracturing water of step (d) to oxidize oxidizable impurities in the fracturing water.

SUMMARY OF THE INVENTION

In accordance with one embodiment of the present invention, there is provided a system for separating oil from water and particulate contaminants from an oil/water/solid mixture, the system comprising: a solid removal system for removing small, medium and large solids from the oil/water/solid mixture to separate an oil and water stream from the solids; and a membrane contactor system for separating the oil from the water in the oil and water stream, wherein the oil coalesces at a first surface of a membrane contactor and is collected at a second surface of the membrane contactor, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

In accordance with another embodiment of the present invention, there is provided a method for removing oil from water and particulate and solid contaminants from an oil/water/solid mixture, the method comprising the steps of: removing small, medium and large solids from the oil/water/solid mixture, with a solid removal system, to form an oil and water stream; and separating the oil from the water in the oil and water stream with a membrane contactor system, wherein the oil coalesces at a first surface of a membrane contactor and is collected at a second surface of the membrane contactor, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

In accordance with yet another embodiment of the present invention, there is provided a method for separating oil from water and particulate contaminants from an oil/water/solid mixture, the method comprising the steps of: removing at least one of small, medium and large solids, from the oil/water/solid mixture to form an oil and water stream, with at least one of a sand filter, a rock filter, a
porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, a strainer and gravity; and separating the oil from the water with a hollow fiber membrane contactor; and collecting the oil separated thereby wherein the oil coalesces at a first surface of the membrane contactor and is collected at a second surface of the membrane contactor, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

In one embodiment, the present invention is a system for separating oil from water and particulate contaminants from a oil/water/solid mixture, comprising: a solid removal system for removing small, medium and large solids from a oil/water/solid mixture to form a oil and water stream containing only solids small enough to pass into the contactor; and a membrane contactor system for separating the oil from the water in the oil and water stream, wherein the oil coalesces at a first surface of the membrane contactor and is collected at the second surface of the membrane contactor. In one aspect, the at least one of small, medium or large solids are removed with at least one of a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, a strainer or gravity. In another aspect, the at least one of small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells and/or cellular debris, and oil sands tailings. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid stream(s), oil contaminated water or brine, drilling mud, produced water and oil sands tailings. In another aspect, the oil/water/solid mixture processed is not subjected to gravity separation prior to processing. In another aspect, the oil/water/solid mixture processed is subjected to gravity separation prior to processing. In another aspect, the oil/water/solid mixture is at least one of an oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings are processed by the system within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from removal of large solids. In another aspect, the membrane contactor is defined further as a hydrophobic membrane or membrane module that
comprises hollow fiber microporous membranes. In another aspect, the hydrophobic hollow fiber membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous Polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof. In another aspect, the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques. In another aspect, the oil separated from the water by the membrane contactor is mixed with a countercflowing solvent, wherein the at least one countercflowing solvent selected from non-polar solvents, alkanes such as hexane, aromatic solvents such as benzene, toluene, ethers such as diethyl ether, halogenated solvents such as chloroform, dichloromethane, and esters such as ethyl acetate. In another aspect, the wherein the countercflowing oil is oil recovered from a similar liquid source using the membrane contactor operated without a recovery fluid or by another method. In another aspect, the oil/water/solid mixture is from a bioreactor. In another aspect, the system further comprises a membrane cleaning system that removes debris that clogs the membrane contactor system and/or a detector that detects a clog of the membrane contactor system.

Another embodiment of the present invention is a method for removing oil from particulate and solid contaminants from a flowing stream of an oily-water and solid liquid mixture comprising the steps of: removing small, medium and large solids from a oil/water/solid mixture with a solid removal system to form a oil and water stream containing solids small enough to pass into the membrane contactor; and separating the oil from the water in the oil and water stream with a membrane contactor system in the presence of solids, wherein the oil coalesces at a first surface of the membrane contactor and is collected at the second surface of the membrane contactor. In one aspect, the at least one of small, medium or large solids are removed with a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, a strainer or gravity. In another aspect, the at least one of small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids. In another aspect, the oil/water/solid mixture is at least one of an oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid stream, oil contaminated water or brine, drilling mud, produced water, cells and/or cellular debris, and oil sands tailings. In another aspect, the oil/water/solid mixture is not subjected to gravity separation prior to processing. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings are processed by the system within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from
extraction. In another aspect, the membrane contactor is defined further as a hydrophobic membrane or membrane module that comprises hollow fiber microporous membranes. In another aspect, the hydrophobic hollow fiber membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous Polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof. In another aspect, the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques. In another aspect, the oil separated from the water by the membrane contactor is mixed with a counterflowing solvent, wherein the at least one counterflowing solvent selected from non-polar solvents, alkanes such as hexane, aromatic solvents such as benzene, toluene, ethers such as diethyl ether, halogenated solvents such as chloroform, dichloromethane, and esters such as ethyl acetate. In another aspect, the counterflowing oil is oil recovered from a similar liquid source using the membrane contactor without a recovery fluid or by another method. In another aspect, the oil/water/solid mixture is from a bioreactor. In another aspect, the method further comprises the steps of removing a clog from the membrane contactor system. In another aspect, the method further comprises the steps of detecting a clog at the membrane contactor system.

Yet another embodiment of the present invention is a system for separating oil from water and particulate contaminants from a oil/water/solid mixture, comprising the steps of: removing at least one of small, medium or large solids from a oil/water/solid mixture to form a oil and water stream with at least one of a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, or a sieve, strainer; and separating the oil from the water with a hollow fiber membrane contactor; and collecting the oil separated thereby, wherein the oil coalesces at a first surface of the membrane contactor and is collected at the second surface of the membrane contactor. In one aspect, the at least one of small, medium or large solids are removed with at least one of a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, or a strainer. In another aspect, the at least one of small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells and/or cellular debris, and oil sands tailings. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings. In another aspect, the oil/water/solid mixture processed is not subjected to gravity separation prior to processing. In another aspect, the oil/water/solid mixture processed is
subjected to gravity separation prior to processing. In another aspect, the oil/water/solid mixture is at least one of a oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings are processed by the system within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from removal of large solids. In another aspect, the membrane contactor is defined further as a hydrophobic membrane or membrane module that comprises hollow fiber microporous membranes. In another aspect, the hydrophobic hollow fiber membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous Polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof. In another aspect, the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques. In another aspect, the oil separated from the water by the membrane contactor is mixed with a counterflowing solvent, wherein the at least one counterflowing solvent selected from non-polar solvents, alkanes such as hexane, aromatic solvents such as benzene, toluene, ethers such as diethyl ether, halogenated solvents such as chloroform, dichloromethane, and esters such as ethyl acetate. In another aspect, the wherein the counterflowing oil is oil recovered from a similar liquid source using the membrane contactor operated without a recovery fluid or by another method. In another aspect, the oil/water/solid mixture is from a bioreactor. In another aspect, the system further comprises a membrane cleaning system that removes debris that clogs the membrane contactor system and/or a detector that detects a clog of the membrane contactor system.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the features and advantages of the present invention, reference is now made to the detailed description of the invention along with the accompanying figures and in which:

Figure 1 shows the basic components of the enhanced oil recovery method and system of the present invention; and

Figure 2 shows the processing details and results from using the present invention; and

Figure 3 shows more processing details and results from using the present invention; and

Figure 4 shows the separation of solids and oil recovery using the present invention.
DETAILLED DESCRIPTION OF THE INVENTION

While the making and using of various embodiments of the present invention are discussed in detail below, it should be appreciated that the present invention provides many applicable inventive concepts that can be embodied in a wide variety of specific contexts. The specific embodiments discussed herein are merely illustrative of specific ways to make and use the invention and do not delimit the scope of the invention.

To facilitate the understanding of this invention, a number of terms are defined below. Terms defined herein have meanings as commonly understood by a person of ordinary skill in the areas relevant to the present invention. Terms such as “a”, “an” and “the” are not intended to refer to only a singular entity, but include the general class of which a specific example may be used for illustration. The terminology herein is used to describe specific embodiments of the invention, but their usage does not delimit the invention, except as outlined in the claims.

The method of the present invention includes a process to recover oil from oil-rich sources containing high levels of solids, e.g., fluids produced from drilling that includes water, brine, sand, rocks and other non-hydrocarbon liquids and solids that comprise hydrocarbons that the user wants to recover or remove from the liquid. The process involves initial steps to remove physically large solids by gravity settling, filtration and/or centrifugation as non-limiting examples. These steps create a stream that has oil/water and physically small solids. The size restriction on the solids is required to complete the oil/water separation step. The oil/water separation step is accomplished by the previously disclosed non-dispersive contactor method.

The process allows oil recovery from liquid sources, non-limiting examples such oil industry wastes, oil contaminated water or brine, drilling mud, produced water and oil sands tailings. Currently, oil is recovered by skimming following gravity settling, combined with up-front filtration, centrifugation or the like. A non-oil dispersive membrane contactor is not currently used to promote more rapid or efficient oil recovery as it is believed to clog too easily. Surprisingly, the present inventors have found the system disclosed herein to provide robust, long-term separation of oil from mixed sources such as oil industry wastes, oil contaminated water or brine, drilling mud, produced water, oil sands tailings, oil from renewable sources such as bacteria, cyanobacteria, yeast, algae, plants, insects, and the like.

It was found by the present inventors that oil recovery using the non-dispersive contactor is faster, free of solids and less expensive than other techniques. The present invention overcomes the problem with a potential environmental hazard of long term settling ponds full of
oily water. Further, oil removal from liquid sources makes subsequent processing steps on the water more cost effective or efficient and of course, the oil recovered can be sold.

As used herein the term “oil/water/solid mixture” encompasses water based liquids containing any of the following in any combination; insoluble oils (hydrocarbons and hydrocarbon-rich molecules of commercial value), rocks, sand, cells and/or cellular debris, insoluble particulates having diameters from, e.g., 100 nm to 1000 micrometers, water, brine, salts, gums, drilling fluids or muds, solvents (e.g., diesel). The slurry may also contain a solvent that was used to pre-treat cells to liberate compounds of interest.

The term “oil” as used herein refers to, e.g., hydrocarbon or hydrocarbon-rich molecules including a complex mixture of lipids, hydrocarbons, free fatty acids, triglycerides, aldehydes, etc. The compounds included herein may be from, e.g., C₈ (jet fuel compatible) up to C₆₀ (motor oil compatible) or larger.

The term “pumping” comprises all methods of pumping, propelling, or feeding fluid from one location to another employing hoses, lines, tubes ducts, pipes, or pipelines including under pressure. It also includes gravity flow of fluid.

The present invention describes a method for recovering oil from oil/water/solid mixtures using hydrophobic microporous hollow fiber membrane. The system can also include, but does not require a recovery fluid, which can be a hydrophobic liquid, a biodiesel, an oil or mixtures thereof. The use of a solid removal system and a hydrophobic microporous hollow fiber membrane provides a non-dispersive method of coalescing and recovering the oil without the need of gravity separation. A simple schematic representation of the method of the present invention is depicted in Figure 1.

Figure 1 shows the basic components of the enhanced oil recovery method and system of the present invention 10. A liquid and solid mixture 12, that may include oil, water, solids, sand, particulates, gums and other waste, is first passed through a coarse filtration system 14 that removes the largest solids from the liquid and solid mixture 12, to leave an oil, water, medium and small solids mixture 16. Next, centrifugation 18 is used to remove the medium solids to leave an oil, water and small solids mixture. The oil, water and small solids mixture is applied to a fine filtration system 20 that removes the smallest solids, such as coarse sand and fine sand, or any remaining medium and large solids (if any). The oil, water and particulates mixture that were not removed by the fine filtration system 20 are applied to a contactor system 22, that draws the oil from the oil, water and particulates mixture, which allows for further processing of
the oil that can be removed, recaptured, or reprocessed and that leaves a stream of water and any particulates from which the oil has been removed.

Figure 2 shows the processing details and results from using the present invention in which oil industry waste (e.g., starting material) was centrifuged to separate the heavy and the light solids. The heavy solids are shown at the bottom of the centrifugation, however, the light solids remained at the top of the tube.

Figure 3 shows more processing details and results from using the present invention in which water is added to the oil industry waste (e.g., starting material) from which the heavy/large solids have been removed by using filters followed by centrifugation. Following centrifugation, the light solids, oil and water remain, which are then flowed into the contactor for isolation or removal of the oil.

Oil Industry Liquid stream Processing. Three 5-gal buckets of oil based drilling mud waste from different sources (e.g., A, B and C) are used. All three appeared to contain significant solids and appear very viscous. Each bucket contains approximately 4 gals. The material appeared to be made up of larger rocks and pebbles of varying sizes, some grasses, mud, oil, and water.

Preparation of Processing Material A. A 1 mL sample of each bucket was centrifuged and indicated that the material contained heavy and light solids. The heavy solids were more uniform in apparent composition in A, so this sample was prioritized to be processed first. A sieve screen was used to remove large particles. Fibrous material, possibly grass, was removed along with small gravel, sand etc. Approximately one gallon of material was removed. The filtered A material was filtered three times using a 40 micron filter and set up for testing using 2.5 inch by 8 inch Liqui-Cel X-50 module. Approximately one gal of A material is lost in the filtration.

In another example, two gals of original A material is added to one gal of distilled water and charged to feed tank. A feed rate of 100 lb/hr was used. After approximately 1-2 minutes, the flow through the membrane stops, due to the presence of solids that are too large to pass through the entry orifice of the module. In certain examples, the membrane is unblocked by repeated water flushing including flowing water in the opposite direction.

In another example, approximately two gallons of water was added to feed to dilute the material prior to centrifugation. The diluted material was pumped from a feed tank to the centrifuge. The feed was centrifuged (and can be centrifuged in multiple passes). Following
centrifugation, the resulting A material looks very fluid-like. In one example, the centrifuged and diluted A material is filtered using a 10 micron filter.

In another example, approximately 3 gals of A material is charged to a feed tank. A shell side feed was mixed continuously in the feed tank. A pressure differential of between 23-25 psi was used. Pressure drop across the shell side was approx. 2 to 5 psi. Approximately 118 ml of oil recovered using 2.5 inch diameter membrane using a shell side rate = 50-100 lb/hr, which included multiple complete passes with no signs of plugging or fouling.

The process for drilling mud may include: (1) course filtration to remove large particles (grass, gravel, sand etc.); (2) dilute with water (optional); (3) centrifuge to remove majority of remaining solids; (4) filtration to remove solids greater than 10, 20, 30 or 40 microns; and (5) feed the aqueous slurry on shell side of microporous hollow fiber membrane to recover oil on tube side.

The skilled artisan will recognize that some streams will either have no solids or solids that already meet the size selection criteria for processing (less than 10, 20, 30, 40 or 50 microns), so they may not need any pre-processing. If it is the case that some of the solids will stick to the membrane and cause a clog, a cleaning processes is used to remove the solids from the membrane to continue use. The present invention may also include a clog detector that determines if the membrane contactor system has become at least partially or fully clogged. Whether or not a clog is detected (e.g., if a clog detector is not used and rather a regular or sporadic cycle or maintenance is used), the invention may also include a system or method for cleaning the membrane contactor, e.g., physical-mechanical cleaning, use of chemicals, backflow, pressurized water, brine or other solvents or other methods for removing debris from the membrane contactor system. Thus, the present invention may also include one or more systems for cleaning, flushing and regenerating the membrane.

In certain examples, the streams may have been partially or completely gravity settled and/or may be predominantly oil with solids and comparatively small amounts of water. To separate the solids from the oil it may be necessary to apply pressure to the stream as it enters the solid removal system and/or the stream may have to be heated (in one example, steam is applied to the stream to both heat the stream and increase the water content).

It was found that the present invention can be operated with or without a counter-flowing recovery fluid. Therefore, the systems and methods can operate with or without a recovery fluid to recover the oil.
In other embodiments, the present invention can be used upstream from other oil-recovery or water polishing processes. The present invention can be used to pre-process oil-contaminated water prior to using other technology that reduces the level of hydrocarbons in the water to trace amounts. For example, using the present invention a drilling platform can process oil-contaminated water, so-called “dirty” water, that has been processed using the present invention prior to reuse of the water for, e.g., water flood or drilling operations. The present invention can be used to pre-process oil-contaminated water with a high oil content to reduce that oil content to, e.g., 500 ppm. Subsequent processing steps and technology can then be used to lower the oil content down into the 1PPM range or less. By pre-processing the oil-contaminated water to a lower range of oil in ppm, water polishing technology that reduces the ppm of oil into acceptable ranges will have an improved half-life and will be able to process oil-contaminated water with a reduced oil load more effectively. One such technology for use following the use of the present invention, is a “smart sponge” technology to remove hydrocarbons from water, e.g., that developed by AbTech®. The AbTech® Smart Sponge can be used to polish the water to very low level of hydrocarbons, but the saturated smart sponges can then be burned to take advantage of the BTUs in the hydrocarbons.

Another such technology that can be used downstream from the present invention used produced water absorbents (PWA), such as OSorb®, that absorbs the oil from produced water streams. As with the smart sponges, the OSorb® technology can take the pre-processed oil-contaminated water from the present invention and then reduce the amount of hydrocarbons to very low levels. Again, by pre-processing the oil-contaminated water to a lower range of oil in ppm, the PWA technology that reduces the ppm of oil into acceptable ranges will have an improved half-life and will be able to process oil-contaminated water with a reduced oil load more effectively.

Figure 4 shows the results from using the present invention on oil field samples. Briefly, following the separation, oil field solids were allowed to dry onto membrane fibers. Dried pieces of membrane were prepared and treated with various agents to identify agents that could remove the solids from the fibers. A strip of membrane was soaked for 10 minutes in, from left to right, 5% NaOH, Isopar L, gasoline, diesel and toluene. In each case, an untreated piece of membrane with dried solids is shown for comparison. The results show that caustic was ineffective in removing dried solids, while each of the hydrophobic liquids was able to remove dried solids. Gasoline, diesel and toluene were more effective than isopar L.
It is contemplated that any embodiment discussed in this specification can be implemented with respect to any method, kit, reagent, or composition of the invention, and vice versa. Furthermore, compositions of the invention can be used to achieve methods of the invention.

It will be understood that particular embodiments described herein are shown by way of illustration and not as limitations of the invention. The principal features of this invention can be employed in various embodiments without departing from the scope of the invention. Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, numerous equivalents to the specific procedures described herein.

All publications and patent applications mentioned in the specification are indicative of the level of skill of those skilled in the art to which this invention pertains.

The use of the word "a" or "an" when used in conjunction with the term "comprising" in the claims and/or the specification may mean "one," but it is also consistent with the meaning of "one or more," "at least one," and "one or more than one." The use of the term "or" in the claims is used to mean "and/or" unless explicitly indicated to refer to alternatives only or the alternatives are mutually exclusive, although the disclosure supports a definition that refers to only alternatives and "and/or." Throughout this application, the term "about" is used to indicate that a value includes the inherent variation of error for the device, the method being employed to determine the value, or the variation that exists among the study subjects.

As used in this specification and claim(s), the words "comprising" (and any form of comprising, such as "comprise" and "comprises"), "having" (and any form of having, such as "have" and "has"), "including" (and any form of including, such as "includes" and "include") or "containing" (and any form of containing, such as "contains" and "contain") are inclusive or open-ended and do not exclude additional, unrecited elements or method steps.

The term "or combinations thereof as used herein refers to all permutations and combinations of the listed items preceding the term. For example, "A, B, C, or combinations thereof is intended to include at least one of: A, B, C, AB, AC, BC, or ABC, and if order is important in a particular context, also BA, CA, CB, CBA, BCA, ACB, BAC, or CAB. Continuing with this example, expressly included are combinations that contain repeats of one or more item or term,
such as BB, AAA, AB, BBC, AAABCCCC, CBBAAA, CABABB, and so forth. The skilled artisan will understand that typically there is no limit on the number of items or terms in any combination, unless otherwise apparent from the context.

As used herein, words of approximation such as, without limitation, "about", "substantial" or "substantially" refers to a condition that when so modified is understood to not necessarily be absolute or perfect but would be considered close enough to those of ordinary skill in the art to warrant designating the condition as being present. The extent to which the description may vary will depend on how great a change can be instituted and still have one of ordinary skilled in the art recognize the modified feature as still having the required characteristics and capabilities of the unmodified feature.

In general, but subject to the preceding discussion, a numerical value herein that is modified by a word of approximation such as "about" may vary from the stated value by at least ±1, 2, 3, 4, 5, 6, 7, 10, 12 or 15%.

The scope of the claims should not be limited by the preferred embodiments set forth in the examples, but should be given the broadest interpretation consistent with the description as a whole.
WHAT IS CLAIMED IS:

1. A system for separating oil from water and particulate contaminants from an oil/water/solid mixture, the system comprising:
   a solid removal system for removing small, medium and large solids from the oil/water/solid mixture to separate an oil and water stream from the solids; and
   a membrane contactor system for separating the oil from the water in the oil and water stream, wherein the oil coalesces at a first surface of a membrane contactor and is collected at a second surface of the membrane contactor,
   wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

2. The system of claim 1, wherein the small, medium or large solids are removed with at least one of a hydrocyclone, a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, a strainer and gravity.

3. The system of claim 1, wherein the small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids.

4. The system of claim 1, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings.

5. The system of claim 1, wherein the oil/water/solid mixture processed is not subjected to gravity separation prior to processing.
6. The system of claim 1, wherein the oil/water/solid mixture processed is subjected to gravity separation prior to processing.

7. The system of claim 4, wherein the oil/water/solid mixture is processed within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from removal of the large solids.

8. The system of claim 1, wherein the membrane contactor is defined further as a hydrophobic membrane or membrane module that comprises hollow fiber microporous membranes.

9. The system of claim 8, wherein the hydrophobic hollow fiber microporous membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof.

10. The system of claim 9, wherein the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques.

11. The system of claim 1, wherein the oil separated from the water by the membrane contactor is mixed with a counterflowing recovery fluid, wherein the counterflowing recovery fluid is selected from non-polar hydrophobic liquids, alkanes, aromatic solvents, ethers, halogenated solvents and esters.

12. The system of claim 11, wherein the counterflowing oil is oil recovered from a similar liquid source using the membrane contactor operated without a recovery fluid or by another method.
13. The system of claim 1, wherein the oil/water/solid mixture is from a bioreactor.

14. The system of claim 1, further comprising a membrane cleaning system that removes debris that clogs the membrane contactor system.

15. The system of claim 1, further comprising clog detector that detects a clog at the membrane contactor system.

16. A method for removing oil from water and particulate and solid contaminants from an oil/water/solid mixture, the method comprising the steps of:

   removing small, medium and large solids from the oil/water/solid mixture, with a solid removal system, to form an oil and water stream; and

   separating the oil from the water in the oil and water stream with a membrane contactor system, wherein the oil coalesces at a first surface of a membrane contactor and is collected at a second surface of the membrane contactor,

   wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

17. The method of claim 16, wherein the small, medium or large solids are removed with a hydrocyclone, a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve or a strainer.

18. The method of claim 16, wherein the small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids.
19. The method of claim 16, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings.

20. The method of claim 16, wherein the oil/water/solid mixture is not subjected to gravity separation prior to processing.

21. The method of claim 19, wherein the oil/water/solid mixture is processed within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from extraction.

22. The method of claim 16, wherein the membrane contactor is defined further as a hydrophobic membrane or membrane module that comprises hollow fiber microporous membranes.

23. The method of claim 22, wherein the hydrophobic hollow fiber microporous membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof.

24. The method of claim 23, wherein the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques.

25. The method of claim 16, wherein the oil separated from the water by the membrane contactor is mixed with a countercflowing recovery fluid, wherein the countercflowing recovery fluid is selected from non-polar hydrophobic liquids, alkanes, aromatic solvents, ethers, halogenated solvents and esters.
26. The method of claim 25, wherein the counterflowing recovery fluid is oil recovered from a similar liquid source using the membrane contactor without a recovery fluid or by another method.

27. The method of claim 16, wherein the oil/water/solid mixture is from a bioreactor.

28. The method of claim 16, further comprising the steps of removing a clog from the membrane contactor system.

29. The method of claim 16, further comprising the steps of detecting a clog at the membrane contactor system.

30. A method for separating oil from water and particulate contaminants from an oil/water/solid mixture, the method comprising the steps of:

   removing at least one of small, medium and large solids, from the oil/water/solid mixture to form an oil and water stream, with at least one of a sand filter, a rock filter, a porous ceramic material, a centrifuge, a mesh, a particulate filter, a sieve, a strainer and gravity; and

   separating the oil from the water with a hollow fiber membrane contactor; and collecting the oil separated thereby wherein the oil coalesces at a first surface of the membrane contactor and is collected at a second surface of the membrane contactor, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water, cells, cellular debris and oil sands tailings.

31. The method of claim 30, wherein the small, medium or large solids are removed with a sand filter, a porous ceramic material, a centrifuge or a mesh.
32. The method of claim 30, wherein the small, medium or large solids are removed in the following sequence: large solids, medium solids and small solids.

33. The method of claim 30, wherein the oil/water/solid mixture is at least one of oil industry liquid streams, oil contaminated water or brine, drilling mud, produced water and oil sands tailings.

34. The method of claim 30, wherein the oil/water/solid mixture is not subjected to gravity separation prior to processing.

35. The method of claim 30, wherein the oil/water/solid mixture is subjected to gravity separation prior to processing.

36. The method of claim 33, wherein the oil/water/solid mixture is processed within 1, 2, 4, 6, 8, 12, 24, 26, 48 or 72 hours from extraction.

37. The method of claim 30, wherein the membrane contactor is defined further as a hydrophobic membrane or membrane module that comprises hollow fiber microporous membranes.

38. The method of claim 37, wherein the hydrophobic hollow fiber microporous membrane comprises polyethylene, polypropylene, polyolefins, polyvinyl chloride (PVC), amorphous polyethylene terephthalate (PET), polyolefin copolymers, poly(etheretherketone) type polymers, surface modified polymers, mixtures or combinations thereof.
39. The method of claim 38, wherein the surface modified polymers comprise polymers modified chemically at one or more halogen groups by corona discharge or by ion embedding techniques.

40. The method of claim 30, wherein the oil separated from the water by the membrane contactor is mixed with a countercflowing recovery fluid, wherein the countercflowing recovery fluid is selected from non-polar hydrophobic liquids, alkanes, aromatic solvents, ethers, halogenated solvents and esters.

41. The method of claim 40, wherein the countercflowing recovery fluid is oil recovered from a similar liquid source using the membrane contactor without a recovery fluid or by another method.

42. The method of claim 30, wherein the oil/water/solid mixture is from a bioreactor.

43. The method of claim 30, further comprising a membrane cleaning system that removes debris that clogs the membrane contactor system.

44. The method of claim 30, further comprising clog detector that detects a clog at the membrane contactor system.

45. The system of claim 1, wherein the oil separated from the water by the membrane contactor is mixed with a countercflowing recovery fluid, and the countercflowing recovery fluid is a non-polar hydrophobic liquid, an alkane, an aromatic solvent, an ether, a halogenated solvent or an ester.
46. The system of claim 45, wherein the counterflowing recovery fluid is hexane, benzene, toluene, diethyl ether, chloroform or ethyl acetate.

47. The method of claim 16 or 30, wherein the oil separated from the water by the membrane contactor is mixed with a counterflowing recovery fluid, and the counterflowing recovery fluid is a non-polar hydrophobic liquid, an alkane, an aromatic solvent, an ether, a halogenated solvent or an ester.

48. The method of claim 47, wherein the counterflowing recovery fluid is hexane, benzene, toluene, diethyl ether, chloroform or acetate.
