(57) Abrégé/Abstract:

A system and method (100) for treating, injecting and co-combusting sludge in a municipal waste or other combustor is disclosed. The system includes a sludge receiving and treatment module (200) and a sludge injection and combustion module (300). The sludge is received and stored in one or more storage hoppers (1) where it is first diluted with a liquid (3) and subsequently mixed (13) to a desired homogeneous consistency suitable for pumping. The high liquid content sludge is then pumped (16) to a furnace injection nozzle (19) where it is preferably atomized with steam (29) and sprayed into the combustion zone of the furnace (20). The disclosed system and method increases sludge moisture content and controls the solids content of the sludge to control furnace temperature.

(54) Title: CO-COMBUSTION OF WASTE SLUDGE IN MUNICIPAL WASTE COMBUSTORS**(57) Abstract**

A system and method (100) for treating, injecting and co-combusting sludge in a municipal waste or other combustor is disclosed. The system includes a sludge receiving and treatment module (200) and a sludge injection and combustion module (300). The sludge is received and stored in one or more storage hoppers (1) where it is first diluted with a liquid (3) and subsequently mixed (13) to a desired homogeneous consistency suitable for pumping. The high liquid content sludge is then pumped (16) to a furnace injection nozzle (19) where it is preferably atomized with steam (29) and sprayed into the combustion zone of the furnace (20). The disclosed system and method increases sludge moisture content and controls the solids content of the sludge to control furnace temperature.

**CO-COMBUSTION OF WASTE SLUDGE IN
MUNICIPAL WASTE COMBUSTORS AND OTHER FURNACES**

BACKGROUND OF THE INVENTION

5 **Field of the Invention**

 This invention pertains to municipal solid waste combustors (MWCs) and, by extension, to all steam power generation boilers and other furnaces. It involves handling and disposal by thermal decomposition of waste sludges of variable solids content, including municipal sewage sludge, paper mill sludge, and other industrial sludges, in MWC power boilers and other furnaces which burn municipal solid waste or other fuels.

Background of the Related Art

10 As the options available for communities and industries for sludge disposal decline, a new cost-effective, environmentally sound method of disposal has become desperately needed. In the 1950s and 1960s, sludges were often incinerated in multiple hearth furnaces. However, most of those installations experienced poor combustion and produced extremely adverse air emissions. Accordingly, this approach
15 was largely abandoned in favor of non-combustion disposal technologies.

Co-combustion of sludge, and preferably high carbon content sludge, with other fuels has remained a goal for many years. One approach, discussed repeatedly in technical literature, was to design external thermal drying systems for pre-drying sludge prior to injection into a furnace, so that drying sludge inside the furnace would not be necessary. However, this technology was expensive and even dangerous, because of potential health hazards related to inhalation of fugitive dust and dust explosions.

Other approaches described below involved injection of wet sludge into modern combustion processes. These approaches failed to achieve commercial acceptance of their technologies because of either limited applicability, economic disadvantages or technological disadvantages.

Komline et al. in U.S. Patent No. 3,322,079 noted the synergy in co-combustion of sludge and municipal solid waste (MSW), using high temperature gases from combustion of MSW to dry sludge injected into the furnace by a rotary centrifugal atomizer. However, operating costs of such a system are high and the rotary centrifugal atomizer disclosed is difficult to reliably maintain because of plugging and wear. The rotary atomizer discharges a significant fraction of large particles that do not burn completely, and deposition of material on boiler internals becomes a problem.

Dingwell in U.S. Patent No. 3,838,651 used steam to atomize waste oil in a burner designed to extend into a combustion chamber. However, this invention is limited in scope to waste oils in old-fashioned incinerators, which were not regulated as stringently at the time of invention. Partial combustion was acceptable and regulatory compliance was not identified as a goal. While steam was used for atomization, non-oil, i.e. aqueous, sludges were not considered.

Pan in U.S. Patent No. 3,903,813 developed a device for injecting steam-atomized sludge into a combustion chamber in close proximity to an oil or gas burner. The injection device allows for mixing of a pressurized fluid and sludge in the same pipe, with the mixture exiting a restrictive orifice at the end of the injection pipe, such

that the mixture is flashed to atmospheric pressure inside the furnace in the presence of oil or gas. Co-combustion with MSW and other renewable and fossil fuels is not considered and the device is intended for use primarily with sludges having solids content equal to or less than 5%. The point of sludge injection is limited to an area
5 below an oil or gas burner flame. This device is intended for incineration of sludge only in the presence of an oil or gas burner.

Carpenter in U.S. Patent No. 5,284,405 disclosed a method for entraining sludge particles in a stream of compressed combustion air, but the invention is limited to combustion within a rotary cement kiln. No attempt is made to burn sludge in
10 suspension and regulatory compliance is not addressed.

Goff et al. in U.S. Patent Nos. 5,052,310 and 5,405,537 established a sludge injection system for MWC's using oxygen-enriched air both to atomize sludge being sprayed into a furnace through a nozzle and to offset the loss of boiler efficiency from moisture in the sludge. However, this requires expensive construction of an oxygen-
15 producing plant adjacent to an owner's core production facilities or purchase of large quantities of bottled oxygen. Furthermore, the invention is limited to MWC's only and may require modification to existing combustion air control systems.

Mole in U.S. Patent 5,531,169 injects liquid waste material, primarily contaminated acid, immediately adjacent to a primary fuel burner. The primary purpose
20 of the device is to dissociate acid molecules. The device is intended for air as opposed to steam atomization and the invention is directed to liquid hazardous waste disposal as opposed to sludge disposal and non-hazardous municipal solid waste combustion and conventional power generation.

Guibelin in U.S. Patent No. 5,544,598 developed a nozzle for disposal of slurry, such as pasty or fatty wastes, by spraying onto burning municipal solid waste.
25 However, this device does not involve sludge, and it is not designed for atomizing particles to burn in suspension.

An objective of the present invention is to provide a sludge receiving and treatment system that is capable of handling sludges with a wide range of characteristics (including variable moisture and solids content) and delivering a consistent flow of sludge to the injection system. Previous systems were not designed for and did not address variable sludge consistencies and solids content.

It is also a goal of the present invention to avoid the material handling difficulties typically encountered with sludge having solids contents of 15% and higher.

A further purpose of the present invention is to maximize suspension burning of sludge particles, in order to virtually eliminate the need to burn larger sludge particles.

A still further goal of the present invention is to utilize wastewater, other industrial process liquid wastes, air pollution control slurries, or mixtures thereof, in a sludge pre-combustion treatment process.

SUMMARY OF THE INVENTION

The aforementioned purposes, goals and objectives are achieved by the present invention for treating and injecting sludge into a combustor, which substantially reduces or eliminates the shortcomings that limited commercial viability of prior techniques.

The present invention generally includes a sludge receiving and treatment module and a sludge injection and combustion module. The sludge receiving and treatment module receives and dilutes sludge with a liquid thereby increasing the moisture content of the sludge and the sludge injection and combustion module injects the diluted sludge into a combustion zone of a combustor where the diluted sludge is burned in suspension. The sludge injection and combustion module may simply comprise a sludge injection nozzle which atomizes the diluted sludge with steam and sprays the atomized diluted sludge into the combustion zone of a combustor having

municipal solid waste or another fuel burning therein. Thus, the atomized diluted sludge is burned in suspension above the municipal solid waste or other fuel.

5 In accordance with the preferred embodiment of the present invention, the sludge is received at the receiving and treatment module and stored in one or more storage hoppers where it is first diluted with a dilution liquid, such as water, plant wastewater, other industrial process liquid wastes, pollution control slurries or mixtures thereof. The sludge particle size is then reduced and the sludge is mixed to a desired homogeneous consistency suitable for pumping. The high liquid content sludge is then pumped to a furnace injection nozzle where it is preferably atomized with steam and
10 sprayed into the combustion zone of the furnace.

The steam atomization nozzle utilized in the present invention is specially engineered to allow flash drying and maximum particle size reduction upon contact with the atomizing steam prior to injection into the furnace. This allows for near complete combustion, little or no impact on bottom ash quality and burnout, and treatment of
15 virtually all products of sludge combustion in existing air pollution control systems. Previous inventions did not address the goal of suspension burning.

The present invention is designed to allow delivery, modification, and control of solids content both to maximize the number of potential sludge customers and to stabilize furnace temperature in response to fluctuating primary fuel heating value.

20 Unlike prior systems, the present invention unexpectedly increases sludge moisture content (to the extent liquids used are water-bearing) as a means for controlling furnace temperature. By decreasing furnace temperature, more primary fuel can be added resulting in increased revenues for facilities which are paid for receiving such fuel, such as municipal waste and biomass combustors.

25 For MWCs, MSW heating value fluctuates seasonally and hour-to-hour, depending on the source of solid waste deliveries. The present invention allows for

manual adjustment of sludge characteristics, including solids and carbon content, and flow rate to maintain relatively constant temperature in the furnace resulting in smoother steam generation. Moreover, because the average heating value of MSW has increased significantly since many MWC's were designed, solid waste through-put has
5 been limited by the higher heating value of the fuel. Since solid waste is a major source of revenue for a MWC, reduced through-put capacity can result in reduced revenue. The disclosed method allows for maintaining MWC through-put revenues at higher than design MSW heating value.

The present invention is applicable to sludge having any range of solids content
10 provided that the sludge can be diluted by the addition of aqueous-based solutions and/or other liquids, such as industrial process liquid wastes and pollution control slurries, and the size of solid particles in the sludge can be reduced by agitation and atomization. The present invention is designed to combust sludge having a solids content in the range of 5% to 15% after dilution. This allows for good control and
15 reliability in a commercial application.

For all industrial combustion facilities, the present invention can dispose of plant wastewater and other industrial process liquid wastes, as well as reduce overall air pollution control costs.

For industrial sludge producers such as paper mills and other similar
20 installations, the present invention makes it possible to achieve environmentally sound on-site or local sludge disposal using existing conventional fuel steam boilers, as opposed to continuously increasing sludge hauling and disposal costs to controlled landfills.

A preferred embodiment of the sludge treatment and injection system, as well
25 as other objects, features and advantages of this invention, will be apparent from the following detailed description, which is to be read in conjunction with the accompanying drawing.

73802-49

According to another aspect of the present invention, there is provided a method for co-combusting sludge within a combustor comprising the steps of: receiving sludge; treating said received sludge, by adding a liquid
5 selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, to dilute said sludge and obtain a sludge having a desired moisture content; injecting said treated sludge into a
10 combustion zone of a combustor having a primary solid fuel burning therein; and burning said treated sludge in suspension within said combustion zone of said combustor.

According to still another aspect of the present invention, there is provided a system for co-combusting
15 sludge within a combustor, comprising: a sludge receiving and treatment module for receiving and treating sludge, by adding a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and
20 mixtures thereof, to dilute said sludge and obtain a sludge having a desired moisture content; and a sludge injection and combustion module for injecting said treated sludge into a combustion zone of a combustor having a primary solid fuel burning therein, wherein said treated sludge is burned in
25 suspension within said combustion zone of said combustor.

According to yet another aspect of the present invention, there is provided a method for co-combusting sludge within a combustor, comprising the steps of:
controlling the moisture content of a diluted sludge
30 utilizing a solids controller; agitating said diluted sludge thereby reducing the size of the particles within said sludge; mixing said diluted sludge to a desired homogeneous

73802-49

consistency suitable for pumping; injecting said diluted sludge into a combustion zone of a combustor having a primary solid fuel burning therein; and burning said diluted sludge in suspension within said combustion zone of said combustor.

According to a further aspect of the present invention, there is provided a system for co-combusting sludge within a combustor, comprising: a sludge receiving and treatment module for receiving and diluting sludge with a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, thereby increasing the moisture content of said sludge; a solids controller for monitoring and varying said moisture content of said sludge; and a sludge injection and combustion module for injecting said diluted sludge into a combustion zone of a combustor having a primary solid fuel burning therein, wherein said diluted sludge is burned in suspension within said combustion zone of said combustor.

According to yet a further aspect of the present invention, there is provided a system for co-combusting sludge within a municipal solid waste combustor, comprising: a sludge receiving and treatment module for receiving and diluting sludge with a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, thereby increasing the moisture content of said sludge; a solids controller for monitoring and varying said moisture content of said sludge; and a sludge injection nozzle for atomizing said diluted sludge with steam and spraying said atomized diluted sludge into a combustion zone of a combustor having municipal solid

73802-49

waste burning therein, wherein said atomized diluted sludge is burned in suspension above said municipal solid waste.

According to still a further aspect of the present invention, there is provided a system for co-combusting
5 sludge within a combustor, comprising: a sludge receiving and treatment module for receiving and diluting sludge with a liquid thereby increasing the moisture content of said sludge; and a sludge injection and combustion module for injecting said diluted sludge into a combustion zone of a
10 combustor having a primary solid fuel burning therein, wherein said diluted sludge is burned in suspension within said combustion zone of said combustor, wherein said sludge receiving and treatment module comprises: a hopper for receiving and storing said sludge; a mixer for receiving
15 said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge; and a solids controller for monitoring the solids content of the diluted sludge within said mixer and for varying the amount of
20 sludge received from said hopper and the amount of liquid received from said liquid source.

According to another aspect of the present invention, there is provided a system for co-combusting sludge within a municipal solid waste combustor, comprising:
25 a sludge receiving and treatment module for receiving and diluting sludge with a liquid thereby increasing the moisture content of said sludge; and a sludge injection nozzle for atomizing said diluted sludge with steam and spraying said atomized diluted sludge into a combustion zone
30 of a combustor having municipal solid waste burning therein, wherein said atomized diluted sludge is burned in suspension above said municipal solid waste, wherein said sludge

73802-49

receiving and treatment module comprises: a hopper for receiving and storing said sludge; a mixer for receiving said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with
5 said liquid thereby diluting said sludge; and a solids controller for monitoring the solids content of the diluted sludge within said mixer and for varying the amount of sludge received from said hopper and the amount of liquid received from said liquid source.

10 According to yet another aspect of the present invention, there is provided a system for co-combusting sludge within a combustor, comprising: a sludge receiving and treatment module for receiving and treating sludge; and a sludge injection and combustion module for injecting said
15 treated sludge into a combustion zone of a combustor, wherein said treated sludge is burned in suspension within said combustion zone of said combustor, said sludge injection and combustion module including: an injection nozzle for atomizing said sludge and spraying said atomized
20 sludge into said combustion zone of said combustor; a sludge tank for receiving and storing sludge from said sludge receiving and treatment module, said sludge tank having a mixer for continuously agitating said sludge within said sludge tank; a pump in fluid communication with said sludge
25 tank and said injection nozzle for delivering said sludge from said sludge tank to said injection nozzle; a discharge line for delivering said sludge from said sludge tank to said pump; and a conditioner interposed in said discharge line for shredding said sludge before entering said pump.

BRIEF DESCRIPTION OF THE DRAWING

Figure 1 is a schematic diagram of a preferred sludge treatment and injection system formed in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

5 Referring to Figure 1, the preferred sludge treatment and injection system 100 generally includes two modules: a sludge receiving and treatment module 200; and a sludge injection and combustion module 300. It is contemplated that the sludge receiving and treatment module 200 may be physically separate from the injection and combustion module 300. It is also conceivable that all or portions of the sludge
10 receiving and treatment module 200 may be incorporated within the mode of shipping sludge, such as by specialized trucks which dilute and pre-mix sludge in transit. However, the preferred system 100 illustrated in Figure 1 includes both modules on-site with a municipal waste combustor (MWC), power boiler or other furnace.

In the preferred system 100, sludge is shipped to the receiving and treatment
15 module 200 in any conventional manner, such as by truck or by pipeline. When shipped by truck, the sludge may be processed in a batch-mode or may be stored until a sufficient amount is available for a semi-continuous type operation. When sludge is delivered in a continuous fashion, such as by pipeline, the system can be easily adapted to operate in a continuous processing mode.

20 In either mode, incoming sludge with variable moisture content, typically in the range of about 5% to 50% solids content, preferably in the range of about 15% to 45%, is received in enclosed hopper 1. Preferably, the design of enclosed hopper 1 allows for sludge delivery and storage in an odor-free and hands-off manner. Multiple hoppers with overflow provisions may be provided depending on the amount of sludge input and
25 whether a continuous or a batch process is utilized. Variable speed screw conveyor 2 at the bottom of hopper 1 delivers sludge to variable speed rotating drum mixer 3, which

also receives a dilution liquid, which may include water, plant wastewater, other industrial process liquid wastes, air pollution control slurries, or mixtures thereof, through line 4. Solids content transmitter 5 provides continuous read-out to solids controller 6, a control panel set by an operator to control the amounts of solids added to drum mixer 3 from screw conveyor 2, by adjusting the speed of variable speed drive 7. Solids controller 6 also opens and closes dilution valve 8 as required to add the dilution liquid to achieve the desired solids content in drum mixer 3. The optimal desired solids content of the sludge is about 10% but may range between about 5% and 15% after dilution. It has been found that this range provides maximum ease of handling while at the same time allows effective sludge combustion. Received sludges having a 5% to 15% solids content may be able to bypass the mixer 3 and be discharged directly from the hopper 1 to a sludge pump suction tank 10.

Metering and mixing in drum mixer 3 is preferably a batch process in that incoming sludge is mixed with a dilution liquid to a desired solids content before moving to the next step of the system. This allows maximum flexibility in establishing the desired solids content from the widest possible range of incoming sludge characteristics.

There also may be periods when the average heating value of the MSW is lower than normal. This usually occurs during periods of heavy rainfall causing higher moisture content in the MSW. During such periods, it may be beneficial for furnace temperature stabilization to inject sludge mixture with a higher heating value. The present invention allows for manual adjustment to increase the sludge heating value. This is achieved by mixing the sludge to a higher solids content and/or by using as part or all of the sludge mixture, a higher carbon content sludge, such as high fiber paper mill sludge that would be received and separately stored in one or more of the storage hoppers.

Variable speed rotating drum mixer 3 operates in a manner similar to a cement mixer in that the agitating action of the rotating drum mixer 3 reduces particle size and

facilitates mixing of the sludge into a homogenous fluid suitable for pumping. When the desired solids content is achieved in drum mixer 3, it discharges through line 9 into enclosed sludge pump suction tank 10.

5 Sludge pump suction tank 10 stores the desired sludge mixture prior to injection into the furnace. The size of the tank is determined by the operating parameters of the particular furnace and whether a batch or continuous process is utilized. Sludge pump suction tank 10 includes a level controller 11 which controls variable speed drive 12 of the drum mixer 3 to adjust the flow rate leaving drum mixer 3 in order to maintain a constant level in sludge pump suction tank 10. Sludge pump suction tank 10 also
10 includes a mixer 13 which continuously agitates the sludge to prevent the sludge from settling or congealing and to thereby maintain a homogenous fluid state.

Sludge is drawn out the bottom of suction tank 10 through line 14 into a conditioner 15 which chops up and shears any large pieces of material before entering a variable speed progressive cavity pump 16. (In the alternative embodiment, where
15 sludge is pumped directly from the customer or from delivery trucks, the conditioner may be moved or an additional conditioner may be placed in the receiving line to minimize the risk of large particle contaminants coming from the customer.) One feature of the present invention is the relative ease with which the diluted sludge flows, which allows for the use of a progressive cavity pump. Conventional systems, pumping
20 sludge with higher solids content, i.e. over 15% to 25%, require heavy duty piston pumps or reciprocating pumps which are more expensive and also difficult to maintain. The progressive cavity pump 16 of the present invention provides cost-effective and easy handling of sludge having solids content up to about 15%.

Pump 16 is driven by variable speed drive 17 and discharges through line 18 to
25 either feed recirculation line 26 back to suction tank 10 or to feed sludge atomizing nozzle 19 for injection into the combustion zone 24 of the furnace 20.

The purpose of recirculation line 26 is to maintain adequate flow through pump 16, in accordance with the pump manufacturer's specification, while avoiding excessive pressure build-up in line 18 to the furnace 20 when sludge demand to the furnace is low. With certain pumps, if flow through the pump is too low, the pump may overheat. Additionally, recirculation back into suction tank 10 also helps to continuously agitate the sludge when not flowing to the furnace. Although preferred, the recirculation line 26 may be eliminated if the pump 16 possesses some form of minimum flow rate and maximum pressure control and the suction tank 10 adequately keeps the sludge agitated without recirculation.

Recirculation line 26 includes a flow controller 25 which modulates recirculation control valve 27 to ensure the proper minimum flow and to stabilize nozzle sludge pressure. When the demand for sludge injection into the furnace 20 is low, flow controller 25 opens recirculation control valve 27 to allow the sludge to recirculate back into suction tank 10 to maintain minimum flow rates and stable pressure, thereby preventing overheating of pump 16.

Sludge flow to the furnace 20 is controlled by programmable controller 21 in response to a demand signal from furnace temperature controller 22, based on furnace flue gas temperature. As furnace temperature rises above a set point established by programmable controller 21, flow controller 23 modulates the speed of variable speed drive 17, which controls the speed of pump 16 and the flow of sludge to nozzle 19 where it is preferably atomized with steam and sprayed into the combustion zone 24 of furnace 20.

While other injection methods may be utilized, steam atomization is preferred because the high temperature steam has the effect of preheating the sludge and also dispersing the sludge into fine particles for nearly complete combustion in suspension. It is also contemplated that with advances in pumping technology and/or by pre-heating and thereby reducing the viscosity of the sludge, higher solids content sludge may be pumped through the system all the way to the injection nozzle. In this case, the

atomization steam could act as the dilution medium whereby prior dilution of the sludge would not be necessary. Thus, with steam atomization, dilution of the sludge could occur later at the injection nozzle as opposed to the sludge receiving and treatment module.

5 As illustrated in Figure 1, steam is piped from steam header 28 through line 29 to pressure control valve 30. In furnace systems which do not involve internal steam generation, steam may be provided from an external source. In either system, a programmable controller 21 modulates pressure control valve 30 to maintain a set differential pressure between steam and sludge at nozzle 19. Tests have shown that
10 optimum differential pressure depends on solids content and other sludge characteristics. For example, it has been found that for sludge having about 10% solids content, a minimum steam pressure of 50 psig, and a minimum sludge pressure of 25 psig, at the nozzle results in sustainable atomized sludge flow at a flow rate of about 3 gallons per minute. To achieve higher flow rates, higher pressures at the nozzle are
15 utilized. As a result, sludge disposal rates of up to 5% dry solids to MSW disposal capacity can be achieved.

 Sludge injection nozzle 19 is specially chosen for its ability to inject steam into the sludge stream before the discharge point of the nozzle. This allows for preheating and partial flash drying of sludge and sets the stage for additional energy release at the
20 point of nozzle discharge. This design specifically minimizes sludge particle size to ensure nearly complete suspension burning in the combustion zone 24 of furnace 20. Previous inventions allowed some fraction of large sludge particles to drop into the bottom ash system 31. Larger particles tend to burn incompletely, resulting in elevated levels of unburned material in bottom ash, which could result in adverse chemical
25 composition of the bottom ash, when tested for compliance with environmental regulations. Suspension burning ensures nearly complete combustion of each sludge particle, with fly ash leaving furnace 20 at duct 32 for transport to the air pollution control system, which is designed to handle all fly ash products of combustion in full regulatory compliance.

Sludge injection nozzle 19 is also specially engineered with a large free cross-sectional area preferably at least 0.365 square inches to minimize plugging potential. It also preferably features a protruding corkscrew at the discharge end which results in a helical discharge at the nozzle. Accordingly, the helical discharge of superheated
5 sludge has a circular velocity as opposed to a linear projection to better dissipate kinetic energy at the nozzle and to prevent impingement of sludge particles on furnace internals thereby further enhancing suspension burning of sludge particles. A preferred sludge atomization nozzle is the Bete Model No. SA2100 which is commercially available from Bete Fog Nozzle Inc., of Greenfield, Massachusetts.

10 Location of the sludge injection point depends on the sludge characteristics of the individual application and the design of the furnace. The preferred sludge injection system is designed for flexibility of application. Accordingly, injection point location is guided by problem-solving potential within the constraints of good combustion practice, such as residence time, furnace exit temperature, and complete turbulence.

15 The preferred sludge treatment and injection system is designed for simplicity of interface with an existing furnace combustion control system. Relays are provided in programmable controller 21 for establishing steam flow before sludge flow, and for automatic shutoff of sludge flow in the event of upsets such as low steam flow in the nozzle or a boiler fuel trip. No air is added with the sludge, so detailed interfaces with
20 combustion air controls system are not required. Heat from the atomizing steam plus the heating value of the sludge tends to offset the heat lost to evaporating liquids in the sludge. Therefore, existing combustion air controls require only a small bias or no compensation at all when the preferred sludge injection system is operating.

25 Previous sludge combustors strived to introduce sludge having high solids content into the furnace because it is known that injecting sludge having low solids content and high moisture content into a furnace has the effect of reducing furnace temperature. Other factors being constant, the energy required to evaporate the moisture in the sludge results in a net heat loss of the furnace. Consequently,

elaborate steps to eliminate heat loss from sludge, such as de-watering and pre-heating, are often taken to produce a sludge which will not adversely affect furnace temperature. Steps have also been taken to enrich the combustion chamber with oxygen in an effort to minimize heat loss in the furnace.

5 The present invention takes the counterintuitive approach of increasing moisture content of incoming sludge. Increased moisture allows better and more cost-effective handling of the sludge through the system. Moreover, the resulting cooling effect from injecting high moisture content sludge into a municipal waste combustion furnace can be countered by increasing the input of municipal solid waste. The resulting cooling
10 effect can also be countered by increasing turbulence in the furnace and utilizing oxygen that would be lost because of under-agitated turbulence. Thus, controlling the furnace temperature in this manner allows for increased solid waste input which in turn increases revenues for the MWC facility.

 Additionally, lowering the furnace flame temperature by injecting high moisture
15 content sludge has the surprising effect of significantly reducing the level of NO_x emissions from the furnace. Thus, the present invention also has the potential as a revenue producing air pollution control system for NO_x reduction.

 The preferred sludge treatment and injection system is not limited by any type of boiler or fuel type, and it has the potential to open an entirely new route to solving
20 difficult combustion-related problems. Mass burn MWC's often have slagging problems caused by high-temperature melting of ash. In this case, the preferred sludge injection system can provide cooling in a critical area to reduce slagging. The preferred sludge injection system can also minimize corrosion problems caused by localized high temperature chloride corrosion in refuse derived fuel MWC's by improving turbulence,
25 mixing, and temperature control. Conventional fossil fuel boilers also experience slagging and corrosion in various forms and the preferred sludge injection system can be applied to attack these problems as well. All boilers face increasingly strict air pollution control regulations. The preferred sludge injection system also has the

potential to provide a new method of emissions control while simultaneously solving a local sludge disposal problem.

Example

5 A system according to the present invention was tested in which diluted paper and sewage sludge were injected into an operating conventional municipal waste combustor.

10 The combustor facility selected for testing has three mass burn refractory MWC's, each rated at 120 tons per day. Normal operation is with two combustors operating and one on stand-by. The combustors are tied to two waste heat boilers and associated air pollution control trains. Each air pollution control train consists of an electrostatic precipitator and spray absorber. The selected facility is permitted to burn up to 240 tons per day of municipal solid waste (MSW) and generates for sale up to 60,000 pounds per hour of super-heated steam at 230 psig and 500° F.

15 Minor modifications were made to the existing combustor facility to allow for receiving, diluting, mixing, storage and pumping of sludge. A plastic mixing tank having a capacity of 1800 gallons was installed at the facility and a Nemo progressive cavity pump with variable speed drive manufactured by Nietzsche was connected to the mixing tank. The pump used had a capacity of about 100 gallons per minute at a speed of 60 rpm. For this test, however, the speed was reduced to about 10 rpm to achieve the
20 desired sludge flow. A sludge recirculation system was implemented wherein an amount of sludge could be recirculated back to the mixing tank from the pump discharge. During this test, pressure and flow control through the recirculation system were done manually. One of the facility's combustor units was also modified to allow spraying and steam atomization of the sludge into the combustor. A Bete Fog Nozzle
25 (same Model #SA2100 as described above) was installed in the combustor as close as possible to the active burning zone and an injection panel was utilized to allow for control of steam header and nozzle pressure, sludge header and nozzle pressure, and

sludge flow using a magnetic flow meter. The nozzle was chosen for its large flow area (.365 in²) to minimize the potential for plugging with sludge particles.

Sludge having a solids content of about 24 - 40% was received at the facility in drums and roll-off containers. The sludge was manually emptied into the mixing tank which had been pre-filled with an amount of water necessary to dilute this type of sludge to a desired final solids content. A propeller-type mixer was used to agitate and mix the sludge in the tank and the cavity pump was initially operated in a manual recirculation mode to further assist in breaking down lumps in the sludge.

Diluted sludges having solids contents ranging from 2% to about 12% were prepared and tested. It was concluded that a solids content of about 10% offered the best combination of handling characteristics and disposal characteristics in the furnace. Sludge flow rates from 4 - 20 GPM were tested with an optimum flow rate of 10 GPM being selected. The selected flow rate of 10 GPM represents a sludge disposal ratio of 5% dry solids to MSW disposal capacity at the facility. This level demonstrates the ability to co-dispose of all the solid wastes and sewage sludge generated in a typical community.

Diluted sludge was pumped through the cavity pump to the injection nozzle at a pressure in the range of 15 - 25 psig where it was atomized with steam supplied to the nozzle at a temperature of about 390 F and a pressure running in a range similar to the sludge pressure. The onset of sludge injection into the combustor was anticipated by increasing the furnace temperature a few degrees for a short period of time prior to injection. This was accomplished by increasing the MSW feed rate slightly to add more heat within the combustor.

Test data were collected using existing plant instrumentation. Data collection stations were established at the main control room, the sludge mixing and pumping station, the sludge injection station, and the continuous emission monitoring room. Visual observations of the primary combustor conditions were possible using infrared

cameras and monitors located in the main control room. The infrared technology was especially helpful in judging atomization quality inside the combustor. Bottom ash samples were taken at the end of each test run from the burn-out grate just before deposition into the wet bottom ash handling system. Samples were taken from the top
5 of the ash bed to reflect worst case conditions.

During sludge injection, the infrared cameras positioned within the primary combustor detected white spots on the MSW burning grate and an increase in turbulence within the combustor. The burning MSW appeared to brighten upon sludge injection indicating that the turbulence caused by the injected sludge was creating
10 better mixing and therefore better combustion conditions in the furnace. It is believed that less excess oxygen was required while burning the sludge because turbulence in the furnace created by the injection system may have resulted in more efficient use of the excess air in the chamber. Furthermore, there was no noticeable effect on furnace draft as the diluted sludge was injected into the combustor.

Throughout the entire testing program, there were no detectable amounts of sulfur dioxide (SO_2) in stack emissions with or without sludge co-combustion. Similarly, test results showed that carbon monoxide (CO) emissions remained at virtually zero with or without sludge co-combustion. This is important because the absence of CO is a primary indicator of good combustion conditions with no dioxin emissions.
15 Occasional small spikes of CO emissions could be observed from time to time, but these spikes never approached the facility's permit level and were typical of spikes observed when burning 100% MSW. Therefore, there was no impact with regard to SO_2 or CO emissions when co-combusting sludge.
20

Surprisingly however, initial testing of various sludge parameters showed an immediate and consistent reduction in nitrous oxide (NO_x) emissions. It is well known
25 that NO_x emissions can be reduced by lowering flame temperature. However, such a reduction can also cause an increase in CO due to poor combustion. Therefore, good combustion is contained in an envelope where both NO_x and CO emissions are

minimized. Because CO emissions remained close to zero through all sludge injection testing, the NO_x reductions resulting from this test program were considered significant. A summary of these test results is set forth below in Table 1.

Table 1
Summary of NO_x Reductions

Test Number	Average NO _x w/o Injection, Lb/MMbtu	Calculated NO _x From Test Unit, Lb/MMbtu	Calculated NO _x Reduction (%)
1	0.229	0.185	19
2	0.229	0.169	26
3	0.229	0.173	24
4	0.229	0.174	24
5	0.229	0.217	5
6	0.229	0.145	37

Similar testing of particulate, metals and dioxins/furans emissions revealed emission rates all lower than permit parameters. Ash samples were also collected during the demonstration to determine the impact on ash quality from co-combustion of MSW with sludge. The results were very consistent and showed only a slight increase in loss-on-ignition, from an average of 1.1% to 1.2%, which is extremely low and indicative of good combustion.

In sum, the test program showed that the present invention is an efficient sludge disposal system which is also capable of operating as a furnace temperature control system with no adverse impacts on plant operation, air emissions or ash quality. The test program showed that injecting and co-combusting sludge within a municipal solid waste combustor has the advantage of balancing the heat value of the municipal solid waste thereby allowing increased through-put of MSW to an MWC. Additionally, apparent reductions in NO_x emissions were achieved.

Although the preferred embodiment of the present invention has been described with reference to the accompanying drawing, it is to be understood that the invention is not limited to that precise embodiment, and that other changes and modifications may be made by one skilled in the art without departing from the scope or spirit of the invention.

5

73802-49

CLAIMS:

1. A method for co-combusting sludge within a combustor comprising the steps of:

receiving sludge;

5 treating said received sludge, by adding a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, to dilute said sludge and obtain a sludge having a desired
10 moisture content;

injecting said treated sludge into a combustion zone of a combustor having a primary solid fuel burning therein; and

burning said treated sludge in suspension within
15 said combustion zone of said combustor.

2. The method as defined in claim 1, further comprising the step of:

atomizing said treated sludge with steam prior to injection into said combustion zone.

20 3. The method as defined in claim 1, wherein said combustor is a municipal solid waste combustor and said treated sludge is burned in suspension above municipal solid waste burning therein.

4. The method as defined in claim 1, further
25 comprising the steps of:

monitoring the temperature within said combustor;
and

73802-49

varying the amount of treated sludge injected into said combustor in response to temperature changes within said combustor to control combustor temperature.

5. The method as defined in claim 1, further comprising the steps of:

monitoring the solids content of said treated sludge; and

varying the amounts of sludge and liquid in response to solids content changes of said treated sludge.

10 6. A system for co-combusting sludge within a combustor, comprising:

a sludge receiving and treatment module for receiving and treating sludge, by adding a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, to dilute said sludge and obtain a sludge having a desired moisture content; and

a sludge injection and combustion module for injecting said treated sludge into a combustion zone of a combustor having a primary solid fuel burning therein, wherein said treated sludge is burned in suspension within said combustion zone of said combustor.

7. The system as defined in claim 6, wherein said sludge injection and combustion module includes an injection nozzle for atomizing said treated sludge with steam and spraying said atomized sludge into said combustion zone of said combustor.

8. The system as defined in claim 6, wherein said combustor is a municipal solid waste combustor and said

73802-49

treated sludge is burned in suspension above municipal solid waste burning therein.

9. The system as defined in claim 6, further comprising a controller for monitoring the temperature within said combustor and for varying the amount of treated sludge injected into said combustor in response to temperature changes within said combustor.

10. The system as defined in claim 6, wherein said sludge receiving and treatment module comprises:

10 a hopper for receiving and storing said sludge;
and

a mixer for receiving said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge.

11. The system as defined in claim 10, further comprising:

a solids controller for monitoring the solids content of said sludge within said mixer and for varying the amount of sludge received from said hopper and the amount of liquid received from said liquid source.

12. The system as defined in claim 11, further comprising:

a solids content transmitter connected to said mixer for continuously monitoring the solids content of said sludge within said mixer and generating a signal to said solids controller in response to solids content changes within said mixer;

73802-49

a conveyor fixed within said hopper for delivering said sludge from said hopper to said mixer in response to a signal generated by said solids controller; and

5 a dilution valve connected to said liquid source for delivering said liquid from said liquid source to said mixer in response to a signal generated by said solids controller.

13. The system as defined in claim 12, wherein said mixer is a drum mixer and said conveyor is a screw conveyor.

10 14. The system as defined in claim 7, wherein said sludge injection and combustion module further comprises:

a sludge tank for receiving and storing said treated sludge from said sludge receiving and treatment module; and

15 a pump in fluid communication with said sludge tank and said injection nozzle for delivering said sludge from said sludge tank to said injection nozzle.

15. The system as defined in claim 14, wherein said sludge tank includes:

20 a level controller for monitoring the level of sludge within said sludge tank and generating a signal to said sludge receiving and treatment module to vary the amount of sludge received in said sludge tank to maintain a constant level of sludge within said sludge tank;

25 a mixer for continuously agitating said sludge within said sludge tank;

a discharge line for delivering said sludge from said sludge tank to said pump; and

73802-49

a conditioner interposed in said discharge line for shredding said sludge before entering said pump.

16. The system as defined in claim 14, wherein said sludge injection and combustion module further comprises:

5 a recirculation line connected between said pump and said sludge tank for recirculating sludge back to said sludge tank;

a recirculation control valve connected to said recirculation line for controlling a flow of sludge through
10 said recirculation line; and

a flow controller connected to said pump for monitoring the flow of sludge through said pump and generating a signal to said recirculation control valve to vary the amount of sludge flowing through said recirculation
15 line.

17. The system as defined in claim 14, wherein said sludge injection and combustion module further comprises:

a temperature controller for monitoring the temperature within said combustor and generating a signal in
20 response to temperature changes within said combustor;

a pump driver connected to said pump for varying the flow of sludge through said pump in response to a signal received from said temperature controller.

18. The system as defined in claim 7, wherein said
25 injection nozzle includes a discharge end for spraying said atomized sludge into said combustion zone of said combustor, and wherein said sludge is atomized and preheated with steam before being sprayed from said discharge end of said nozzle.

73802-49

19. The system as defined in claim 18, wherein said discharge end of said injection nozzle is configured to provide a helical shaped discharge of sludge from said nozzle.

5 20. The system as defined in claim 6, wherein said combustor is a steam power generation combustor.

21. A method for co-combusting sludge within a combustor, comprising the steps of:

controlling the moisture content of a diluted
10 sludge utilizing a solids controller;

agitating said diluted sludge thereby reducing the size of the particles within said sludge;

mixing said diluted sludge to a desired homogeneous consistency suitable for pumping;

15 injecting said diluted sludge into a combustion zone of a combustor having a primary solid fuel burning therein; and

burning said diluted sludge in suspension within said combustion zone of said combustor.

20 22. A system for co-combusting sludge within a combustor, comprising:

a sludge receiving and treatment module for receiving and diluting sludge with a liquid selected from the group consisting of water, aqueous based solutions,
25 plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, thereby increasing the moisture content of said sludge;

73802-49

a solids controller for monitoring and varying said moisture content of said sludge; and

a sludge injection and combustion module for injecting said diluted sludge into a combustion zone of a combustor having a primary solid fuel burning therein, wherein said diluted sludge is burned in suspension within said combustion zone of said combustor.

23. The system as defined in claim 22, wherein said sludge injection and combustion module includes an injection nozzle for atomizing said diluted sludge with steam and spraying said atomized diluted sludge into said combustion zone of said combustor.

24. The system as defined in claim 22, wherein said combustor is a municipal solid waste combustor and said diluted sludge is burned in suspension above municipal solid waste burning therein.

25. The system as defined in claim 22, further comprising a controller for monitoring the temperature within said combustor and for varying the amount of diluted sludge injected into said combustor in response to temperature changes within said combustor.

26. The system as defined in claim 22, wherein said sludge receiving and treatment module comprises:

a hopper for receiving and storing said sludge; and

a mixer for receiving said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge.

73802-49

27. The system as defined in claim 23, wherein said sludge injection and combustion module further comprises:

a sludge tank for receiving and storing said diluted sludge from said sludge receiving and treatment
5 module; and

a pump in fluid communication with said sludge tank and said injection nozzle for delivering said sludge from said sludge tank to said injection nozzle.

28. The system as defined in claim 27, wherein said
10 sludge tank includes:

a level controller for monitoring the level of sludge within said sludge tank and generating a signal to said sludge receiving and treatment module to vary the amount of sludge received in said sludge tank to maintain a
15 constant level of sludge within said sludge tank;

a mixer for continuously agitating said sludge within said sludge tank;

a discharge line for delivering said sludge from said sludge tank to said pump; and

20 a conditioner interposed in said discharge line for shredding said sludge before entering said pump.

29. The system as defined in claim 27, wherein said sludge injection and combustion module further comprises:

a recirculation line connected between said pump
25 and said sludge tank for recirculating sludge back to said sludge tank;

73802-49

a recirculation control valve connected to said recirculation line for controlling a flow of sludge through said recirculation line; and

a flow controller connected to said pump for
5 monitoring the flow of sludge through said pump and
generating a signal to said recirculation control valve to
vary the amount of sludge flowing through said recirculation
line.

30. The system as defined in claim 27, wherein said
10 sludge injection and combustion module further comprises:

a temperature controller for monitoring the
temperature within said combustor and generating a signal in
response to temperature changes within said combustor;

a pump driver connected to said pump for varying
15 the flow of sludge through said pump in response to a signal
received from said temperature controller.

31. The system as defined in claim 23, wherein said
injection nozzle includes a discharge end for spraying said
atomized diluted sludge into said combustion zone of said
20 combustor, and wherein said diluted sludge is atomized and
preheated with steam before being sprayed from said
discharge end of said nozzle.

32. The system as defined in claim 27, wherein said
discharge end of said injection nozzle is configured to
25 provide a helical shaped discharge of sludge from said
nozzle.

33. The system as defined in claim 22, wherein said
combustor is a steam power generation combustor.

73802-49

34. A system for co-combusting sludge within a municipal solid waste combustor, comprising:

a sludge receiving and treatment module for receiving and diluting sludge with a liquid selected from the group consisting of water, aqueous based solutions, plant wastewater, industrial process liquid waste, pollution control slurries and mixtures thereof, thereby increasing the moisture content of said sludge;

a solids controller for monitoring and varying said moisture content of said sludge; and

a sludge injection nozzle for atomizing said diluted sludge with steam and spraying said atomized diluted sludge into a combustion zone of a combustor having municipal solid waste burning therein, wherein said atomized diluted sludge is burned in suspension above said municipal solid waste.

35. The system as defined in claim 34, further comprising a controller for monitoring the temperature within said combustor and for varying the amount of atomized diluted sludge injected into said combustor in response to temperature changes within said combustor.

36. The system as defined in claim 34, wherein said sludge receiving and treatment module comprises:

a hopper for receiving and storing said sludge; and

a mixer for receiving said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge.

73802-49

37. The system as defined in claim 34, further comprising:

a sludge tank for receiving and storing said diluted sludge from said sludge receiving and treatment
5 module; and

a pump in fluid communication with said sludge tank and said injection nozzle for delivering said sludge from said sludge tank to said injection nozzle.

38. The system as defined in claim 37, wherein said
10 sludge tank includes:

a level controller for monitoring the level of sludge within said sludge tank and generating a signal to said sludge receiving and treatment module to vary the amount of sludge received in said sludge tank to maintain a
15 constant level of sludge within said sludge tank;

a mixer for continuously agitating said sludge within said sludge tank;

a discharge line for delivering said sludge from said sludge tank to said pump; and

20 a conditioner interposed in said discharge line for shredding said sludge before entering said pump.

39. The system as defined in claim 37, further comprising:

a recirculation line connected between said pump
25 and said sludge tank for recirculating sludge back to said sludge tank;

73802-49

a recirculation control valve connected to said recirculation line for controlling a flow of sludge through said recirculation line; and

a flow controller connected to said pump for
5 monitoring the flow of sludge through said pump and
generating a signal to said recirculation control valve to
vary the amount of sludge flowing through said recirculation
line.

40. The system as defined in claim 37, further
10 comprising:

a temperature controller for monitoring the
temperature within said combustor and generating a signal in
response to temperature changes within said combustor;

a pump driver connected to said pump for varying
15 the flow of sludge through said pump in response to a signal
received from said temperature controller.

41. The system as defined in claim 34, wherein said
injection nozzle includes a discharge end for spraying said
atomized diluted sludge into said combustion zone of said
20 combustor, and wherein said diluted sludge is atomized and
preheated with steam before being sprayed from said
discharge end of said nozzle.

42. The system as defined in claim 41, wherein said
discharge end of said injection nozzle is configured to
25 provide a helical shaped discharge of sludge from said
nozzle.

43. The system as defined in claim 34, wherein said
combustor is a steam power generation combustor.

73802-49

44. A system for co-combusting sludge within a combustor, comprising:

a sludge receiving and treatment module for receiving and diluting sludge with a liquid thereby
5 increasing the moisture content of said sludge; and

a sludge injection and combustion module for injecting said diluted sludge into a combustion zone of a combustor having a primary solid fuel burning therein, wherein said diluted sludge is burned in suspension within
10 said combustion zone of said combustor,

wherein said sludge receiving and treatment module comprises:

a hopper for receiving and storing said sludge;

a mixer for receiving said sludge from said hopper
15 and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge; and

a solids controller for monitoring the solids content of the diluted sludge within said mixer and for
20 varying the amount of sludge received from said hopper and the amount of liquid received from said liquid source.

45. The system as defined in claim 44, further comprising:

a solids content transmitter connected to said
25 mixer for continuously monitoring the solids content of the diluted sludge within said mixer and generating a signal to said solids controller in response to solids content changes within said mixer;

73802-49

a conveyor fixed within said hopper for delivering said sludge from said hopper to said mixer in response to a signal generated by said solids controller; and

5 a dilution valve connected to said liquid source for delivering said liquid from said liquid source to said mixer in response to a signal generated by said solids controller.

46. The system as defined in claim 45, wherein said mixer is a drum mixer and said conveyor is a screw conveyor.

10 47. A system for co-combusting sludge within a municipal solid waste combustor, comprising:

a sludge receiving and treatment module for receiving and diluting sludge with a liquid thereby increasing the moisture content of said sludge; and

15 a sludge injection nozzle for atomizing said diluted sludge with steam and spraying said atomized diluted sludge into a combustion zone of a combustor having municipal solid waste burning therein, wherein said atomized diluted sludge is burned in suspension above said municipal
20 solid waste,

wherein said sludge receiving and treatment module comprises:

a hopper for receiving and storing said sludge;

25 a mixer for receiving said sludge from said hopper and for receiving said liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge; and

73802-49

a solids controller for monitoring the solids content of the diluted sludge within said mixer and for varying the amount of sludge received from said hopper and the amount of liquid received from said liquid source.

5 48. The system as defined in claim 47, further comprising:

a solids content transmitter connected to said mixer for continuously monitoring the solids content of the diluted sludge within said mixer and generating a signal to
10 said solids controller in response to solids content changes within said mixer;

a conveyor fixed within said hopper for delivering said sludge from said hopper to said mixer in response to a signal generated by said solids controller; and

15 a dilution valve connected to said liquid source for delivering said liquid from said liquid source to said mixer in response to a signal generated by said solids controller.

49. A system for co-combusting sludge within a
20 combustor, comprising:

a sludge receiving and treatment module for receiving and treating sludge; and

a sludge injection and combustion module for injecting said treated sludge into a combustion zone of a
25 combustor, wherein said treated sludge is burned in suspension within said combustion zone of said combustor, said sludge injection and combustion module including:

73802-49

an injection nozzle for atomizing said sludge and spraying said atomized sludge into said combustion zone of said combustor;

5 a sludge tank for receiving and storing sludge from said sludge receiving and treatment module, said sludge tank having a mixer for continuously agitating said sludge within said sludge tank;

a pump in fluid communication with said sludge tank and said injection nozzle for delivering said sludge
10 from said sludge tank to said injection nozzle;

a discharge line for delivering said sludge from said sludge tank to said pump; and

a conditioner interposed in said discharge line for shredding said sludge before entering said pump.

15 50. The system as defined in claim 49, wherein said combustor is a municipal solid waste combustor and said sludge is burned in suspension above municipal solid waste burning therein.

51. The system as defined in claim 49, further
20 comprising a controller for monitoring the temperature within said combustor and for varying the amount of sludge injected into said combustor in response to temperature changes within said combustor.

52. The system as defined in claim 49, wherein said
25 sludge receiving and treatment module comprises:

a hopper for receiving and storing said sludge;
and

73802-49

a mixer for receiving said sludge from said hopper and for receiving a liquid from a liquid source, said mixer mixing said sludge with said liquid thereby diluting said sludge.

5 53. The system as defined in claim 52, wherein said liquid source is a wastewater source.

54. The system as defined in claim 52, wherein said liquid source is an air pollution control liquid source.

55. The system as defined in claim 52, further
10 comprising:

solids controller for monitoring the solids content of the diluted sludge within said mixer and for varying the amount of sludge received from said hopper and the amount of liquid received from said liquid source.

15 56. The system as defined in claim 55, further comprising:

a solids content transmitter connected to said mixer for continuously monitoring the solids content of the diluted sludge within said mixer and generating a signal to
20 said solids controller in response to solids content changes within said mixer;

a conveyor fixed within said hopper for delivering said sludge from said hopper to said mixer in response to a signal generated by said solids controller; and

25 a dilution valve connected to said liquid source for delivering said liquid from said liquid source to said mixer in response to a signal generated by said solids controller.

73802-49

57. The system as defined in claim 56, wherein said mixer is a drum mixer and said conveyor is a screw conveyor.

58. The system as defined in claim 49, wherein said sludge tank includes a level controller for monitoring the
5 level of sludge within said sludge tank and generating a signal to said sludge receiving and treatment module to vary the amount of sludge received in said sludge tank to maintain a constant level of sludge within said sludge tank.

59. The system as defined in claim 49, wherein said
10 sludge injection and combustion module further comprises:

a recirculation line connected between said pump and said sludge tank for recirculating sludge back to said sludge tank;

a recirculation control valve connected to said
15 recirculation line for controlling a flow of sludge through said recirculation line; and

a flow controller connected to said pump for monitoring the flow of sludge through said pump and generating a signal to said recirculation control valve to
20 vary the amount of sludge flowing through said recirculation line.

60. The system as defined in claim 49, wherein said sludge injection and combustion module further comprises:

a temperature controller for monitoring the
25 temperature within said combustor and generating a signal in response to temperature changes within said combustor;

a pump driver connected to said pump for varying the flow of sludge through said pump in response to a signal received from said temperature controller.

73802-49

61. The system as defined in claim 49, wherein said injection nozzle includes a discharge end for spraying said atomized sludge into said combustion zone of said combustor, and wherein said sludge is atomized and preheated with steam
5 before being sprayed from said discharge end of said nozzle.

62. The system as defined in claim 61, wherein said discharge end of said injection nozzle is configured to provide a helical shaped discharge of sludge from said nozzle.

10 63. A method for co-combusting sludge within a combustor, comprising the steps of:

receiving sludge;

agitating said sludge thereby reducing the size of the particles within said sludge;

15 mixing said sludge to a desired homogeneous consistency suitable for pumping;

atomizing said agitated and mixed sludge;

injecting said atomized sludge into a combustion zone of a combustor; and

20 burning said injected sludge in suspension within said combustion zone of said combustor.

64. The method as defined in claim 63, further comprising the step of:

25 atomizing said sludge with steam prior to injection into said combustion zone 24.

65. The method as defined in claim 63, wherein said combustor is a municipal solid waste combustor and said

73802-49

injected sludge is burned in suspension above municipal solid waste burning therein.

66. The method as defined in claim 63, further comprising the steps of:

5 monitoring the temperature within said combustor;
and

varying the amount of sludge injected into said combustor in response to temperature changes within said combustor to control combustor temperature.

10 67. The method as defined in claim 63, further comprising the steps of:

monitoring the solids content of said sludge; and

varying the amounts of sludge and liquid in response to solids content changes of said sludge.
