[57]	Abstract:	<p>Provided is a method for producing pellets by which, when nickel oxide ore is being pelletized and smelted to produce ferronickel, which is an iron-nickel alloy, it is possible to allow the smelting reaction to proceed effectively and to prevent the ferronickel obtained after the smelting reaction from becoming small in size. A method for producing pellets according to the present invention is for producing pellets which are used in producing iron-nickel alloy and which are produced by mixing raw materials including nickel oxide ore and agglomerating the resulting mixture, wherein the method comprises: a mixing step S11 for mixing at least nickel oxide ore, a carbonaceous reducing agent, and iron oxide to generate a mixture; and a pellet formation step S12 for agglomerating the resulting mixture and forming pellets. In the mixing step S11, the mixture is generated such that the total weight of nickel and iron accounts for 30 wt pcnt or more of the total weight of the pellets formed.</p>	

into a smelting furnace (reducing furnace), then reducing and heating. More specifically, as shown in the process chart of FIG. 1, this method for smelting nickel oxide ore includes a pellet production step S1 of producing pellets from nickel oxide ore, a reduction step S2 of reducing and heating the obtained pellets in a reducing furnace at a predetermined reduction temperature, and a recovery step S3 of recovering metal by separating the slag and metal generated in the reduction step S2.

10 <1.1. Pellet Production Step>

The pellet production step S1 produces pellets from nickel oxide ore, which is the raw material ore. FIG. 2 is a process flow chart showing the flow of processing in the pellet production step S1. As shown in FIG. 2, the pellet production step S1 includes a mixing process step S11 of mixing the raw materials including the nickel oxide ore, a pellet formation step S12 of forming (granulating) pellets, which are lumps, using the obtained mixture, and a drying process step S13 of drying the obtained pellets.

(1) Mixing Process Step

The mixing process step S11 is a step of obtaining a mixture by mixing the raw material powders including nickel oxide ore. More specifically, this mixing process step S11 obtains a mixture by mixing at least nickel

oxide ore, which is the raw material ore, a carbonaceous  
reducing agent and iron oxide. It should be noted that,  
otherwise, it is possible to add and mix flux component,  
binder, etc. as necessary. Although the particle size of  
5 these raw materials is not particularly limited, a  
mixture is obtained by mixing raw material powders with a  
particle size on the order of 0.2 mm to 0.8 mm, for  
example.

The nickel oxide ore is not particularly limited;  
10 however, it is possible to use limonite ore, saprolite  
ore, etc.

In addition, powdered coal, pulverized coke, etc.  
are given as the carbonaceous reducing agent, for  
example. This carbonaceous reducing agent is preferably  
15 equivalent in particle size to the aforementioned nickel  
oxide ore.

In addition, as the iron oxide, for example, it is  
possible to use iron ore having an iron quality on the  
order of at least 50%, hematite obtained by wet smelting  
20 of nickel oxide ore, etc.

Otherwise, it is possible to give bentonite,  
polysaccharides, resins, water glass, dewatered cake,  
etc. as the binder, for example. In addition, it is  
possible to give calcium hydroxide, calcium carbonate,  
25 calcium oxide, silicon dioxide, etc. as the flux

component, for example.

An example of the composition of a part of the raw material powders (wt%) is shown in Table 1 noted below.

It should be noted that the composition of the raw

5 material powder is not limited thereto.

[Table 1]

Raw material powders [wt%]	Ni	Fe <sub>2</sub> O <sub>3</sub>	C
Nickel oxide ore	1~2	10~60	—
(Limonite)	1.0~1.2	30~60	—
Iron ore (Iron oxide)	—	80~95	—
Carbonaceous reducing agent	—	—	≒55

Herein, although described in detail later, in the present embodiment, upon mixing at least the nickel oxide ore, carbonaceous reducing agent and iron ore in this

10 mixing process step S11, a mixture is generated such that the total weight of the nickel and iron contained in the pellets formed next in the pellet formation step S12 becomes at least a predetermined proportion. By adjusting the mixture for forming pellets in which the total weight

15 of nickel and iron is at least a predetermined proportion in this way, the smelting reaction of pellets progresses effectively in the reducing heat treatment of the

subsequent step using these pellets (reduction step S2), and thus it is possible to suppress the obtained ferronickel from becoming small grains.

## (2) Pellet Formation Step

5           The pellet formation step S12 is a step of forming (pelletizing) the mixture of raw material powders obtained in the mixing process step S11 into pellets, which are lumps. More specifically, it forms pellets by adding the moisture required in agglomerating to the  
10 mixture obtained in the mixing process step S11, and using a lump production device (such as a rolling granulator, compression molding machine, extrusion machine), etc., or by the hands of a person.

          The pellet shape is not particularly limited;  
15 however, it can be established as spherical, for example. In addition, although the size of the lump made into pellet form is not particularly limited, by passing through the drying process and preheat treatment described later, for example, it is configured so as to  
20 become on the order of 10 mm to 30 mm in size (diameter in case of spherical pellet) of pellet to be charged into the reducing furnace, etc.

          In the present embodiment, the mixture for forming pellets for which the total weight of nickel and iron is  
25 at least a predetermined proportion is prepared in the

mixing process step S11 as mentioned above. Due to this fact, the metal content of nickel and iron will be contained at a predetermined proportion in the pellets obtained in this pellet formation step S12, and in the  
5 reducing heat treatment of the subsequent process of the reduction step S2 using these pellets, the smelting reaction of pellets will progress effectively, and thus it is possible to suppress the obtained ferronickel from becoming small grains. It should be noted that the  
10 details will be described later.

### (3) Drying Process Step

The drying process step S13 is a step of drying the pellets that are lumps obtained in the pellet formation step S12. The pellets (lumps) formed become a sticky  
15 state in which moisture is included in excess at about 50 wt%, for example. Therefore, in order to facilitate handling of this pellet, the drying process step S13 is configured to conduct the drying process so that the solid content of the pellet becomes on the order of 70  
20 wt% and the moisture becomes on the order of 30 wt%, for example.

More specifically, the drying processing on the pellet in the drying process step S13 is not particularly limited; however, it blows hot air at 300°C to 400°C onto  
25 the pellet to make dry, for example. It should be noted

that the temperature of the pellet during this drying process is less than 100°C.

An example of the solid content composition (parts by weight) of the pellet after the drying process is shown in Table 2 noted below. It should be noted that the composition of the pellet after the drying process is not limited thereto.

[Table 2]

Composition of pellet solid content after drying [Parts by weight]	Ni	Fe <sub>2</sub> O <sub>3</sub>	SiO <sub>2</sub>	CaO	Al <sub>2</sub> O <sub>3</sub>	MgO	Binder	Other
Nickel oxide ore	0.5~1.5	30~60	8~30	4~10	1~8	2~9	1 measure	Remainder
Limonite	0.4~0.7	30~60	8~30	4~10	1~8	2~9	1 measure	Remainder

The pellet production step S1 granulates (agglomerates) the mixture of raw material powders including nickel oxide ore, which is the raw material ore, as mentioned above, and dries this, thereby producing pellets. The size of the obtained pellet is on the order of 10 mm to 30 mm, and pellets having strength

that can maintain shape, e.g., strength for which the proportion of pellets breaking is no more than about 1% even in a case causing to drop from a height of 1 m, are produced. Such pellets are able to endure shocks such as dropping upon charging into the reducing furnace in the subsequent process of the reduction step S2, and can maintain the shape of the pellets, and appropriate gaps are formed between pellets; therefore, the smelting reaction in the reduction step S2 will progress suitably.

10        It should be noted that, in this pellet production step S1, it may be configured so as to provide a preheat treatment step of preheat treating the pellets, which are lumps subjected to the drying processing in the aforementioned drying process step S13, at a  
15        predetermined temperature. In this way, by conducting preheat treatment on the lump after the drying process to produce a pellet in this way, it is possible to more effectively suppress heat shock-induced cracking (breaking, crumbling) of pellets. For example, it is  
20        possible to make the proportion of pellets breaking among all pellets charged into the reducing furnace a slight proportion at less than 10%, and thus possible to maintain the shape in at least 90% of the pellets.

More specifically, the pellets after the drying  
25        process are preheat treated at a temperature of 350°C to

600°C in the preheat treatment. In addition, it is preferable to preheat treat at a temperature of 400°C to 550°C. By preheat treating a temperature of 350°C to 600°C, preferably 400°C to 550°C, in this way, it is possible to decrease the crystallization water contained in the nickel oxide ore constituting the pellets, and thus possible to suppress breaking of pellets due to desorption of this crystallization water, even in a case of making the temperature suddenly rise by charging into a reducing furnace at about 1400°C. In addition, by conducting such preheat treatment, the thermal expansion of particles such as the nickel oxide ore, carbonaceous reducing agent, iron oxide, binder and flux component constituting the pellets, becomes two stages and will advance slowly, whereby it is possible to suppress the breakage of pellets caused by the expansion difference between particles. It should be noted that, as the processing time of the preheat treatment, although it is not particularly limited and may be adjusted as appropriate according to the size of the lump containing nickel oxide ore, it is possible to set to a processing time on the order of 10 minutes to 60 minutes, if a lump of normal size for which the size of the obtained pellet will be on the order of 10 mm to 30 mm.

<1.2. Reduction Step>

The reduction step S2 heats the pellets obtained in the pellet production step S1 at a predetermined reduction temperature. By way of the reducing heat treatment of the pellets in this reduction process S2, 5 the smelting reaction progresses, whereby metal and slag are formed.

More specifically, the reducing heat treatment of the reduction step S2 is performed using a smelting furnace (reducing furnace), and reduces and heats the 10 pellets containing nickel oxide ore by loading into the reducing furnace heated to a temperature on the order of 1400°C, for example. In the reducing heat treatment of this reduction step S2, the nickel oxide and iron oxide in the pellet near the surface of the pellet which tends 15 to undergo the reduction reaction first is reduced to make an iron-nickel alloy (ferronickel) in a short time of about 1 minute, for example, and forms a husk (shell). On the other hand, the slag component in the pellet gradually melts accompanying the formation of the shell, 20 whereby liquid-phase slag forms in the shell. In one pellet, the ferronickel metal (hereinafter referred to simply as "metal") and the ferronickel slag (hereinafter referred to simply as "slag") thereby form separately.

Then, by extending the processing time of the 25 reducing heat treatment of the reduction step S2 up to on

the order of 10 minutes further, the carbon component of the surplus carbonaceous reducing agent not contributing to the reduction reaction contained in the pellet is incorporated into the iron-nickel alloy and lowers the melting point. As a result thereof, the iron-nickel alloy melts to become liquid phase.

As mentioned above, although the slag in the pellet melts to become liquid phase, it becomes a mixture coexisting as the separate phases of the metal solid phase and slag solid phase by subsequent cooling, without the blending together of the metal and slag that have already formed separately. The volume of this mixture shrinks to a volume on the order of 50% to 60% when comparing with the loaded pellets.

In the case of the aforementioned smelting reaction progressing the most ideally, it will be obtained as one mixture made with the one metal solid phase and one slag solid phase coexisting relative to one loaded pellet, and becomes a solid in a "potbellied" shape. Herein, "potbellied" is a shape in which the metal solid phase and slag solid phase join. In the case of being a mixture having such a "potbellied" shape, since this mixture will be the largest as a particle size, the time and labor in recovery will lessen and it is possible to suppress a decline in metal recovery rate upon recovering from the

reducing furnace.

It should be noted that the aforementioned surplus carbonaceous reducing agent is not only mixed into the pellets in the pellet production step S1 and, for  
5 example, it may be prepared by spreading over the coke, etc. on the hearth of the reducing furnace used in this reduction step S2.

In the method for smelting nickel oxide ore according to the present embodiment, the pellet  
10 production step S1 generates a mixture so that the total weight of nickel and iron contained in the pellet to be formed becomes at least a predetermined amount, upon mixing at least nickel oxide ore, carbonaceous reducing agent, and iron oxide as mentioned above. By preparing  
15 the mixture in order to form pellets for which the total weight of nickel and iron becomes at least a predetermined amount in this way, the smelting reaction progresses effectively in the reducing heat treatment in the reduction step S2 using these pellets, and thus it is  
20 possible to suppress the obtained ferronickel from becoming small grains.

### <1.3. Separation Step>

The separation step S3 recovers metal by separating the metal and slag generated in the reduction step S2.  
25 More specifically, a metal phase is separated and

recovered from a mixture containing the metal phase (metal solid phase) and slag phase (slag solid phase) obtained by the reducing heat treatment on the pellet.

As a method of separating the metal phase and slag phase from the mixture of the metal phase and slag phase obtained as solids, for example, it is possible to use a method of separating according to specific gravity, separating according to magnetism, cracking by a crusher, etc., in addition to a removal method of unwanted substances by sieving. In addition, it is possible to easily separate the obtained metal phase and slag phase due to having poor wettability, and relative to the aforementioned "potbellied" mixture, for example, it is possible to easily separate the metal phase and slag phase from this "potbellied" mixture by imparting shock such as providing a predetermined drop and allowing to fall, or imparting a predetermined vibration upon sieving.

The metal phase (ferronickel) is recovered by separating the metal phase and slag phase in this way.

## <<2. Formation of Pellets in Pellet Production Step>>

Next, the pellet production step S1 in the method for smelting nickel oxide ore will be explained in further detail. In the aforementioned way, the pellet production step S1 includes a mixing process step S11 of

mixing the raw materials including nickel oxide ore, a pellet formation step S12 of forming pellets, which are lumps, by agglomerating the obtained mixture, and a drying process step S13 of drying the obtained pellets.

5           Then, in the present embodiment, this mixing process step S11 generates a mixture such that the total weight of nickel and iron contained in the pellets formed in the subsequent pellet formation step S12 becomes at least a predetermined proportion, upon mixing at least  
10 the nickel oxide ore, carbonaceous reducing agent and iron oxide. More specifically, it is characterized in preparing mixture so that the total weight of the metal components of nickel and iron contained in the pellets becomes at least 30 wt%.

15           The pellet obtained by preparing the mixture and agglomerating this mixture in this way have a high concentration of iron oxide and nickel oxide in this pellet, and when charged into the reducing furnace in the subsequent process which is the reduction step S2, the  
20 iron oxide and nickel oxide in the pellets will be reduced rapidly to an iron-nickel alloy, i.e. ferronickel (metal), and form a shell.

          The formation of the shell in the reducing heat treatment in the reduction step S2 in the aforementioned  
25 way is important in order to make the smelting reaction

progress ideally, whereby it is possible to effectively obtain ferronickel grains that are the largest in the size of particles, obtained as a mixture of one relative to one charged pellet (mixture made with one metal phase  
5 and one slag phase coexisting). Upon recovering ferronickel from this reducing furnace, the time and labor in recovery thereby decrease, and it is possible to suppress a decline in recovery rate. In addition, it is preferable to prepare a mixture so that the total weight  
10 of the metal components of nickel and iron contained in the pellet becomes at least 35 wt%, whereby it is possible to obtain ferronickel grains stably with the largest grain size.

As the ratio of metal components of nickel and iron  
15 contained in the pellet, although not particularly limited so long as this total weight is at least 30 wt% as mentioned above, when also considering the content ratio of carbonaceous reducing agent in order to make the smelting reaction progress more effectively, it is  
20 preferred to set no more than 55 wt% as the upper limit value thereof. In addition, from the point of a higher Ni quality of the ferronickel grain obtained after the reducing heat treatment in the reduction step S2 being advantageous as a stainless steel raw material, it is  
25 more preferable to generate a mixture so that the total

weight of the metal components of nickel and iron becomes no more than 45 wt%.

In particular, in a case of using limonite or saprolite as the nickel oxide ore, which is the raw material ore, the Ni quality contained in these ores is low at on the order of 1%. For this reason, it is particularly preferable to set the total weight of the aforementioned metal components (nickel and iron) when adding iron oxide such as iron ore to at least 30 wt% and no more than 45 wt%, whereby it is possible to curb the Ni quality in the obtained ferronickel from declining.

In the above way, the present embodiment makes pellets by preparing a mixture by mixing at least nickel oxide ore, carbonaceous reducing agent and iron oxide so that the total weight of nickel and iron contained in the pellet to be formed becomes at least 30 wt%, and agglomerating this mixture, upon producing pellets to be used in the smelting reaction in the reduction step S2. By producing ferronickel, which is an iron-nickel alloy, by using pellets obtained in this way, in the subsequent process which is the reduction step S2, (1) it is possible to make the smelting reaction progress effectively, and (2) it is possible to suppress the ferronickel obtained after the smelting reaction from splitting into small grains.

## EXAMPLES

Hereinafter, the present invention will be explained more specifically by showing Examples and Comparative Examples; however, the present invention is not to be limited to the following Examples.

[Example 1]

While adding a predetermined amount of water, nickel oxide ore (limonite) as the raw material ore (A), carbonaceous reducing agent (B) and iron oxide (C) were mixed so as to make the ratios thereof A:B:C =6:3:5, flux component of limestone and silica sand was further mixed so as to be  $(\text{CaO}+\text{MgO})/\text{SiO}_2 = 0.6$  to 2.5, thereby making a mixture of 50 wt% solid content and 50 wt% moisture. The component composition of nickel oxide ore, carbonaceous reducing agent and iron oxide (iron ore), which are the raw material powders used, is shown in Table 3 noted below.

[Table 3]

Raw material powders [wt%]	Ni	$\text{Fe}_2\text{O}_3$	C	Particle size [mm] (Measurement by sieving method)
Nickel oxide ore	1.0	53	—	0.5
Iron ore	—	85	—	0.7
Carbonaceous	—	—	≒55	0.4

reducing agent				
----------------	--	--	--	--

Next, while adding water into the obtained mixture, it was kneaded by hand to form a spherical lump so that the pellet size when completed would be on the order of 10 mm to 30 mm. Then, this lump was dried so as to be 70  
5 wt% solid content and 30 wt% moisture content, thereby forming a pellet.

The size (diameter) of the obtained pellet was about 17 mm. In addition, the total weight of nickel and iron contained in the pellet was 35 wt%.

10 Ten of the pellets formed were charged inside a reducing furnace heated to the reduction temperature of 1400°C, and the reducing heat treatment was conducted. Then, the state after 10 minutes elapsed since charging into the reducing furnace (completing the reduction  
15 reaction) was observed, and the number of ferronickel grains obtained was counted.

It should be noted that, since the number of ferronickel grains was greater than 10 if splitting in the middle of the smelting reaction (reduction reaction),  
20 the occurrence of splitting was evaluated by measuring the number of ferronickel grains. Since many ferronickel grains became very small at no more than 1 mm in the case of the ferronickel grains becoming 100 or more in number, measurement was stopped in the case of being more than 10

in number.

As a result thereof, the number of ferronickel grains obtained was 10, and the Ni content in this ferronickel was 1.7 wt%.

5        In this way, it was possible to make the smelting reaction progress effectively in Example 1, and thus possible to suppress the ferronickel obtained after the smelting reaction from splitting into small grains.

[Example 2]

10        Except for generating a mixture by mixing the raw material powders so as to make the ratios A:B:C = 5.5:3:4.5, and producing pellets using this mixture, it was carried out similarly to Example 1. It should be noted that the size of the pellets obtained (diameter)  
15        was about 17 mm, and the total weight of nickel and iron in the pellet was 40 wt%.

As a result thereof, the number of ferronickel grains obtained was 10, and the Ni content in this ferronickel was 1.5 wt%.

20        In this way, it was possible to make the smelting reaction progress effectively in Example 2, and thus possible to suppress the ferronickel obtained after the smelting reaction from splitting into small grains.

[Example 3]

25        Except for generating a mixture by mixing the raw

material powders so as to make the ratios A:B:C = 6:3:3,  
and producing pellets using this mixture, it was carried  
out similarly to Example 1. It should be noted that the  
size of the pellets obtained (diameter) was about 17 mm,  
5 and the total weight of nickel and iron in the pellet was  
30 wt%.

As a result thereof, the number of ferronickel  
grains obtained was 10, and the Ni content in this  
ferronickel was 1.7 wt%.

10 In this way, it was possible to make the smelting  
reaction progress effectively in Example 3, and thus  
possible to suppress the ferronickel obtained after the  
smelting reaction from splitting into small grains.

[Example 4]

15 Except for generating a mixture by mixing the raw  
material powders so as to make the ratios A:B:C = 5:3:5,  
and producing pellets using this mixture, it was carried  
out similarly to Example 1. It should be noted that the  
size of the pellets obtained (diameter) was about 17 mm,  
20 and the total weight of nickel and iron in the pellet was  
45 wt%.

As a result thereof, the number of ferronickel  
grains obtained was 10, and the Ni content in this  
ferronickel was 1.3 wt%.

25 In this way, it was possible to make the smelting

reaction progress effectively in Example 4, and thus possible to suppress the ferronickel obtained after the smelting reaction from splitting into small grains.

[Comparative Example 1]

5        Except for generating a mixture by mixing the raw material powders so as to make the ratios A:B:C = 9:3:1, and producing pellets using this mixture, it was carried out similarly to Example 1. It should be noted that the size of the pellets obtained (diameter) was about 17 mm,  
10      and the total weight of nickel and iron in the pellet was 25 wt%.

As a result thereof, the number of ferronickel grains obtained was 83, and thus had split into small grains. It should be noted that the Ni content in this  
15      ferronickel was 2.0 wt%.

Although it was possible to make the smelting reaction progress in Comparative Example 1, the ferronickel obtained after the smelting reaction split into small grains, and thus handling was very difficult.  
20      [Comparative Example 2]

Except for generating a mixture by mixing the raw material powders so as to make the ratios A:B:C = 10:3:0, and producing pellets using this mixture, it was carried out similarly to Example 1. It should be noted that the  
25      size of the pellets obtained (diameter) was about 17 mm,

METHOD FOR PRODUCING PELLETS AND METHOD FOR PRODUCING  
IRON-NICKEL ALLOY

TECHNICAL FIELD

5           The present invention relates to a method for  
producing pellets, and in more detail, relates to a  
method for producing pellets upon processing in a  
smelting step of nickel oxide ore, and a method for  
producing iron-nickel alloy using this.

10

BACKGROUND ART

As methods for smelting nickel oxide ore called  
limonite or saprolite, a method of dry smelting that  
produces nickel matt using a flash smelting furnace, a  
15 method of dry smelting that produces ferronickel using a  
rotary kiln or moving hearth furnace, a method of wet  
smelting that produces a mix sulfide using an autoclave,  
etc. have been known.

Upon charging the nickel oxide ore to the smelting  
20 step, pre-processing is performed for pelletizing, making  
into a slurry, etc. the raw material ore. More  
specifically, upon pelletizing the nickel oxide ore, i.e.  
producing pellets, it is common to mix components other  
than this nickel oxide ore, e.g., binder and reducing  
25 agent, then further perform moisture adjustment, etc.,

INTELLECTUAL PROPERTY OFFICE  
RECEIVED  
2018 MAR 23 PM 3:56

and the total weight of nickel and iron in the pellet was 20 wt%.

As a result thereof, the number of ferronickel grains obtained was 100 or more, and thus had split into 5 small grains. It should be noted that the Ni content in this ferronickel was 4.0 wt%.

Although it was possible to make the smelting reaction progress in Comparative Example 2, the ferronickel obtained after the smelting reaction split 10 into small grains, and thus handling was very difficult.

followed by charging into agglomerate producing equipment to make a lump on the order of 10 to 30 mm, for example (indicated as pellet, briquette, etc.; hereinafter referred to simply as "pellet").

5           Ferronickel is an alloy of iron (Fe) and nickel (Ni), and is made as a raw material of stainless steel mainly; however, if the smelting reaction (reduction reaction) of the aforementioned pellets advances ideally, since one ferronickel grain is obtained for one of these  
10 pellets, it is possible for a comparatively large ferronickel grain to be obtained.

When considering the efficiency of recovering ferronickel grains from a reducing furnace after the reduction reaction, the grain size is important, and if  
15 the ferronickel grain splits in the course of the reduction reaction, not only will handling become difficult, but time and labor will be required in recovery, and depending on the case, a novel recovery apparatus becomes necessary; therefore, it is very  
20 disadvantageous in terms of cost.

For example, Patent Document 1 discloses technology of adjusting excess carbon content of the mixture in a mixing step to make a mixture by mixing raw materials including nickel oxide and iron oxide with carbonaceous  
25 reducing agent, as a pre-treatment method upon producing

ferronickel using a moving hearth furnace.

However, upon producing pellets in the  
aforementioned way, in the case of nickel oxide ore being  
a raw material, if producing ferronickel, which is an  
5 iron-nickel alloy, by adjusting the raw material  
components other than nickel oxide ore in order to make  
so that the smelting reaction progresses effectively, the  
size of the obtained ferronickel grains will become  
smaller at the moment when the smelting reaction ends.

10 If the size of the obtained ferronickel grain  
becomes smaller, there are problems in that this  
ferronickel is far smaller than the size of the pellets  
with a diameter on the order of 10 mm to 30 mm, and split  
to no more than several millimeters; therefore, handling  
15 upon recovering from the reducing furnace is very  
difficult, and the recovery rate declines.

In other words, in a smelting method for producing  
ferronickel, which is an iron-nickel alloy, from nickel  
oxide ore, it is preferable to satisfy both conditions  
20 of: (1) the smelting reaction progressing effectively;  
and (2) suppressing the obtained ferronickel from  
splitting into small grains; however, with the  
conventional smelting technology, it is not possible to  
adequately satisfy the condition (2) in particular, and  
25 thus brings about a decline in recovery rate.

Application, Publication No. 2004-156140

#### DISCLOSURE OF THE INVENTION

##### 5 Problems to be Solved by the Invention

The present invention has been proposed taking account of such a situation, and has an object of providing a method for producing pellets, upon producing ferronickel, which is an iron-nickel alloy, by  
10 pelletizing nickel oxide ore and smelting, that can cause the smelting reaction to progress effectively, and suppress the ferronickel obtained after the smelting reaction from becoming small grains.

##### Means for Solving the Problems

15 The present inventors have thoroughly investigated in order to solve the aforementioned problem. As a result thereof, it was found that, upon producing pellets, when generating a mixture by mixing at least nickel oxide ore, carbonaceous reducing agent and iron oxide, by preparing  
20 a mixture so that the total weight of nickel and iron accounting for the total weight of the obtained pellet becomes at least a predetermined proportion, it becomes a pellet for which the smelting reaction will progress effectively, and can suppress splitting of ferronickel,  
25 which is an iron-nickel alloy obtained after the smelting

reaction. In other words, the present invention provides the following matters.

A first aspect of the present invention is a method for producing pellets to be used for producing an iron-  
5 nickel alloy, and produced by agglomerating a mixture obtained by mixing raw materials including nickel oxide ore, the method including: a mixing process step of generating a mixture by mixing at least the nickel oxide ore, a carbonaceous reducing agent and iron oxide; and a  
10 pellet formation step of forming a pellet by agglomerating the mixture obtained, in which a mixture is generated in the mixing process step such that a proportion of a total weight of nickel and iron accounting for the total weight of the pellet formed is  
15 at least 30 wt%.

According to a second aspect of the present invention, in the method for producing pellets as described in the first aspect, the nickel oxide ore is limonite or saprolite, and a mixture is generated in the  
20 mixing process step such that a proportion of a total weight of nickel and iron accounting for the total weight of the pellet formed is no more than 45 wt%.

A third aspect of the present invention, in the method for producing an iron-nickel alloy that produces  
25 the iron-nickel alloy from nickel oxide ore, the method

including: a pellet production step of producing a pellet from the nickel oxide ore; and a reduction step of heating the pellet obtained at a predetermined reduction temperature, in which the pellet production step

5 includes: a mixing process step of generating a mixture by mixing at least the nickel oxide ore, a carbonaceous reducing agent and iron oxide; and a pellet formation step of forming a pellet by agglomerating the mixture obtained, and in which a mixture is generated in the

10 mixing process step such that a proportion of a total weight of nickel and iron accounting for the total weight of the pellet formed is at least 30 wt%.

#### Effects of the Invention

According to the present invention, upon producing

15 ferronickel, which is an iron-nickel alloy, using pellets of nickel oxide ore, it is possible to cause the smelting reaction to progress effectively, and suppress the ferronickel obtained after the smelting reaction from becoming small grains.

20

#### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a process drawing showing the flow of a method for smelting nickel oxide ore; and

FIG. 2 is a process flowchart showing the flow of

25 processes in a pellet production step of the method for

smelting nickel oxide ore.

#### PREFERRED MODE FOR CARRYING OUT THE INVENTION

Hereinafter, a specific embodiment of the present  
5 invention (hereinafter referred to as "present  
embodiment") will be explained in detail while  
referencing the drawings. It should be noted that the  
present invention is not to be limited to the following  
embodiment, and that various modifications within a scope  
10 not departing from the gist of the present invention are  
possible.

#### <<1. Method for Smelting Nickel Oxide Ore>>

First, a method for smelting nickel oxide ore,  
which is raw material ore, will be explained.  
15 Hereinafter, it will be explained giving as an example a  
method for smelting ( that produces ferronickel (method  
for producing ferronickel) by pelletizing nickel oxide  
ore, which is the raw material ore, then generates metal  
(iron-nickel alloy (hereinafter iron-nickel alloy is  
20 referred to as "ferronickel")) and slag by reduction  
treating these pellets, and then separates this metal and  
slag.

The method for smelting nickel oxide ore according  
to the present embodiment is a method for smelting using  
25 pellets of nickel oxide ore, by charging these pellets

**CLAIMS:**

1. A method for producing pellets to be used for producing an iron-nickel alloy, and produced by  
5 agglomerating a mixture obtained by mixing raw materials including nickel oxide ore, the method comprising:

a mixing process step of generating a mixture by mixing at least the nickel oxide ore, a carbonaceous reducing agent and iron oxide; and

10 a pellet formation step of forming a pellet by agglomerating the mixture obtained,

wherein the nickel oxide ore is limonite or saprolite,

wherein the iron oxide is hematite obtained by wet smelting of nickel oxide ore or iron ore having an iron  
15 quality of at least 50 wt%, and

wherein a mixture is generated in the mixing process step such that a proportion of a sum weight of nickel and iron accounting for the total weight of the pellet formed is at least 30 wt%.

20

2. The method for producing pellets according to claim 1, wherein a mixture is generated in the mixing process step such that a proportion of a sum weight of nickel and iron accounting for the total weight of the  
25 pellet formed is no more than 45 wt%.

3. A method for producing an iron-nickel alloy that produces the iron-nickel alloy from nickel oxide ore, the method comprising:

30 a pellet production step of producing a pellet from the nickel oxide ore; and

a reduction step of heating the pellet obtained at a predetermined reduction temperature,

INTELLECTUAL PROPERTY OFFICE  
RECEIVED

wherein the pellet production step includes:

a mixing process step of generating a mixture by mixing at least the nickel oxide ore, a carbonaceous reducing agent and iron oxide; and

5 a pellet formation step of forming a pellet by agglomerating the mixture obtained,

wherein the nickel oxide ore is limonite or saprolite,

10 wherein the iron oxide is hematite obtained by wet smelting of nickel oxide ore iron ore or iron ore nickel oxide ore having an iron quality of at least 50 wt%, and

wherein a mixture is generated in the mixing process step such that a proportion of a sum weight of nickel and iron accounting for the total weight of the pellet formed  
15 is at least 30 wt%, and

wherein, in the reduction step, the obtained pellet is heated at a predetermined reduction temperature, whereby shell of iron-nickel alloy is formed near the surface of the pellet.

20

4. The method for producing pellets according to claim 3, further comprising a drying process step of drying the pellets that are lumps obtained in the pellet formation step.

25

5. The method for producing pellets according to claim 4, further comprising a preheat treatment step of preheat treating the pellets after the drying process at a predetermined temperature.

30

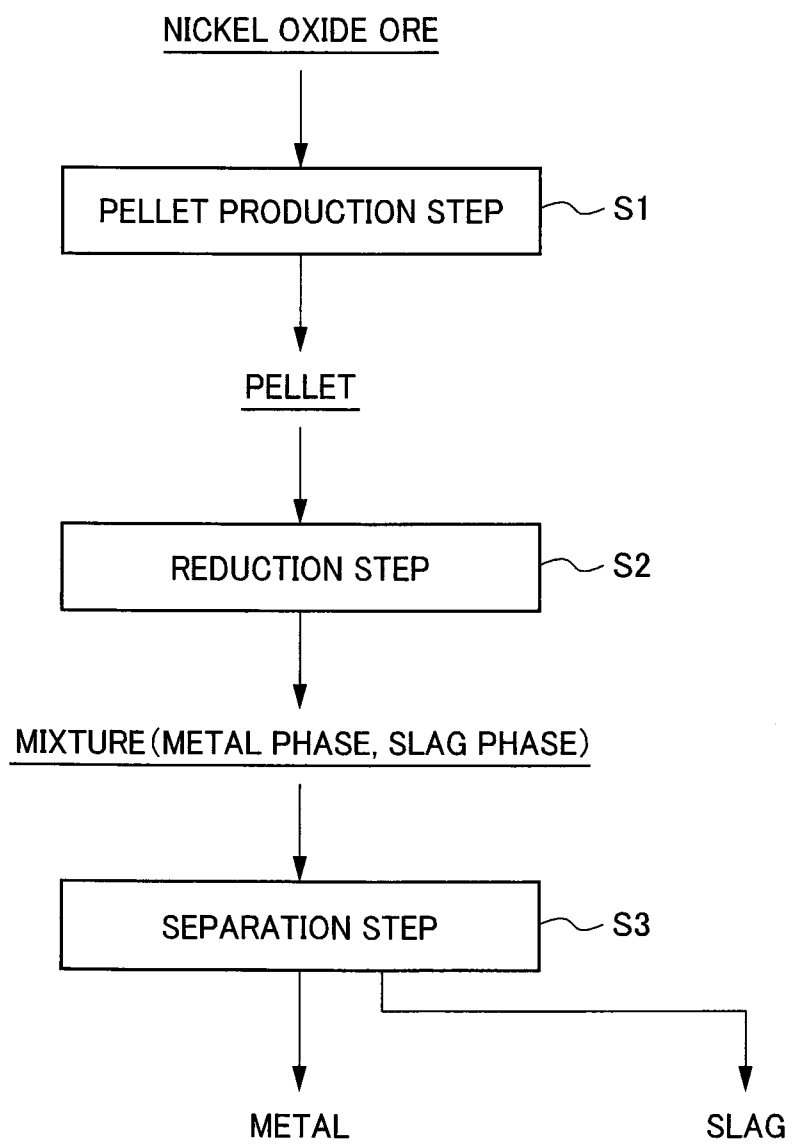

6. The method for producing pellets according to claim 5, wherein the pellets after the drying process are

preheat treated at a temperature of 350°C to 600°C in the preheat treatment step.
