**ABSTRACT**

A robotic medical system and method of performing a medical procedure on a patient are provided. Control signals are conveyed from a remote controller to a drive unit, and a drive unit is operated in accordance with the control signals to advance a first medical instrument within an anatomical vessel (e.g., a blood vessel) of the patient, to advance a second medical instrument outside of the anatomical vessel, and to respectively actuate first and second tools located on the first and second medical instruments, in unison, to perform at least one of a suturing procedure and a sewing procedure on the anatomical vessel. The control signals may be conveyed from the remote controller to the drive unit in response to user commands. The user commands may be movements made at a user interface that correspond to movements of the first and second medical instruments.

RELATED APPLICATIONS

[0001] This application is a continuation of U.S. application Ser. No. 10/639,785, filed Aug. 12, 2003, which claims benefit of priority from U.S. Application Ser. No. 60/403,621, filed Aug. 14, 2002. This application is also related to U.S. application Ser. Nos. ____ (Attorney Docket No. HNMD-EA005CON2), ____ (Attorney Docket No. HNMD-EA005CON3), ____ (Attorney Docket No. HNMD-EA005CON4), ____ (Attorney Docket No. HNMD-EA005CON5), and ____ (Attorney Docket No. HNMD-EA005CON6), all of which are filed on the same date herewith. The entire disclosures of the above applications are expressly incorporated herein by reference.

BACKGROUND OF THE INVENTION

[0002] Robotically controlled surgical instruments are usually controlled from a master station at which a surgeon or other medical practitioner is situated. The master station may include one or more input devices manipulated by the user for, in turn, controlling, at an operative site, respective instruments used in performing a surgical procedure or application.

SUMMARY OF THE INVENTION

[0003] In accordance with a first aspect of the present inventions, a robotic medical system is provided. The robotic medical system comprises an intraluminal medical instrument having a first tool adapted to be disposed at a first region within an anatomical vessel, and an extraluminal medical instrument having a second tool adapted to be disposed at a second region outside of the anatomical vessel opposite the first region. In one embodiment, the intraluminal medical instrument is flexible, and the extraluminal medical instrument is rigid. In this case, the intraluminal medical instrument may be configured for being introduced at the first region through a natural body orifice or percutaneously, while the extraluminal medical instrument may be configured for being introduced at the second region through a surgical opening or laparoscopically. In another embodiment, both the intraluminal medical instrument and extraluminal medical instrument may be flexible.

[0004] The robotic medical system further comprises at least one electromechanical driver (e.g., one that has a motor array) coupled to the intraluminal medical instrument and extraluminal medical instrument. The robotic medical system further comprises a remote controller configured for respectively directing the electromechanical driver(s) to independently control movements of the intraluminal and extraluminal medical instruments, and to respectively control the first and second tools, in unison, to perform at least one of a suturing procedure and a sewing procedure on the anatomical vessel. In one embodiment, the remote controller is coupled to the electromechanical driver(s) via external cabling. The remote controller may optionally have a user interface for receiving commands from a user. In this case, the movements made at the user interface may correspond to movements of the intraluminal and extraluminal instruments.

[0005] The robotic medical system may be configured to perform the suturing or sewing procedure in any one of a variety of manners. For example, in the case of a suturing procedure, one of the tools may have a needle, and another of the tools may have a tissue grasper. The tissue grasper may be configured for grasping a fold of a wall of the anatomical vessel, and the needle may be configured for passing a suture through the wall fold. In the case of a sewing procedure, one of the tools may have a needle, and the other of the tools may be a hook end effector that cooperates with the needle to perform the sewing procedure. The tool with the needle may have a presser foot, in which case, the needle may be configured for reciprocating relative to the presser foot. The needle may be configured for pulling a loop of suture material through a wall of the anatomical vessel, and the hook end effector may be configured for grabbing the loop of material before the needle pulls the loop of suture material through the anatomical vessel wall.

[0006] In accordance with a second aspect of the present inventions, a method of performing a medical procedure on a patient is provided. The method comprises conveying control signals from a remote controller to a drive unit, and operating the drive unit in accordance with the control signals to advance a first medical instrument within an anatomical vessel (e.g., a blood vessel) of the patient, to advance a second medical instrument outside of the anatomical vessel, and to respectively actuate first and second tools located on the first and second medical instruments, in unison, to perform at least one of a suturing procedure and a sewing procedure on the anatomical vessel. In an optional method, the control signals may be conveyed from the remote controller to the drive unit in response to user commands. The user commands may be movements made at a user interface that correspond to movements of the first and second medical instruments.

[0007] In one method, the first medical instrument is introduced within the patient through a natural body orifice or percutaneously, and the second medical instrument is introduced within the patient through a surgical opening or laparoscopically. The suturing or sewing procedure may be performed on the anatomical vessel using suturing or sewing tools in the manner described above. Various medical procedures may be performed on an anatomical vessel, including securing the ends of two segments of the anatomical vessel together, securing a stent to the anatomical vessel, transversely securing another anatomical vessel to a side wall of the anatomical vessel, constricting a sphincter located in the anatomical vessel (e.g., at the base of a ureter or at a gastro-esophageal junction).

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] The foregoing and other objects, features and advantages of the invention will be apparent from the following more particular description of preferred embodiments of the invention, as illustrated in the accompanying drawings in which like reference characters refer to the same parts throughout the different views. The drawings are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention.

[0009] FIG. 1 is a perspective view of one embodiment of a robotic surgical system in which the principles of the present invention are applied;

[0010] FIG. 2 schematically illustrates a surgical procedure using intraluminal and extraluminal instruments, one flexible and one rigid;
FIG. 3 illustrates respective end effectors of rigid and flexible instruments used in performing a suturing procedure at a wall of a lumen;

FIG. 3A shows a next step in the suturing process with the needle having punctured the anatomic wall;

FIG. 3B shows still another suturing step with the suture being pulled through the wall, and further illustrating the placement of a viewing endoscope attached internally;

FIG. 3C is a schematic illustration of dual end effectors used in a sewing technique for attaching vessel segments together;

FIG. 3D illustrates the completion of the sewing technique of FIG. 3C;

FIG. 3E illustrates a surgical procedure in the stomach using dual instruments, a flexible instrument passing into the stomach and either a rigid or flexible instrument outside the stomach wall;

FIG. 3F schematically shows the end of the sewing or suturing technique at the stomach wall;

FIG. 3G illustrates the dual instruments used for securing or re-securing an internal object such as a stent in an artery, vein, or other anatomic lumen or vessel;

FIG. 3H illustrates a first step in a procedure for attaching one vessel to another such as in bypass surgery;

FIG. 3I illustrates a second step in a procedure for attaching one vessel to another;

FIG. 3J illustrates a third step in a procedure for attaching one vessel to another;

FIG. 3K shows the use of dual instruments in a bladder procedure;

FIG. 3L illustrates the use of dual instruments in a stomach procedure;

FIG. 4 is an exploded perspective view of another version of the cable drive mechanism and tool in accordance with the present invention;

FIG. 5 is a top plan view of the instrument insert itself;

FIG. 6 is a perspective view of another embodiment of the present invention;

FIG. 7 is an enlarged detail perspective view of the tool;

FIG. 8 is a perspective view at the tool;

FIG. 9 is a side elevation view of the needle driver;

FIG. 10 is a perspective view of an embodiment of a flexible or connectable wrist just proximal to the tool;

FIGS. 11-14 illustrate different end effector constructions that may be used with either flexible or rigid instruments;

FIG. 15 is a perspective view at the slave station of the system of FIG. 1 illustrating the interchangeable instrument concepts;

FIG. 16 is a cross-sectional view through the storage chamber and as taken along line 16-16 of FIG. 15;

FIG. 17 is a longitudinal cross-sectional view, as taken along line 17-17 of FIG. 16, and showing both a stored articulating instrument and a stored fluid dispensing;

FIG. 18 is a schematic diagram of the instrument systems of the present invention as deployed through the urethra for a surgical procedure in the bladder;

FIG. 19 gives further details of the bladder procedures of FIG. 18; and

FIG. 20 illustrates still another concept using a single controllable instrument.

DETAILED DESCRIPTION OF THE INVENTION

A description of preferred embodiments of the invention follows.

FIG. 1 is a perspective view of one embodiment of a robotic surgical system in which the principles of the present invention are applied. FIG. 1 illustrates a surgical instrument system 10 that includes a master M at which a surgeon 2 manipulates an input device, and a slave station S at which is disposed a surgical instrument. In FIG. 1 the input device is illustrated at 3 being manipulated by the hand or hands of the surgeon. The surgeon is illustrated as seated in a comfortable chair 4. The forearms of the surgeon are typically resting upon armrests 5.

FIG. 1 illustrates a master assembly 7 associated with the master station M and a slave assembly 8 associated with the slave station S. Assembly 8 may also be referred to as a drive unit. Assemblies 7 and 8 are interconnected by means of cabling 6 with a controller 9. As illustrated in FIG. 1, controller 9 typically has associated therewith one or more displays and a keyboard. Reference is also made to, for example, the aforementioned U.S. Ser. No. 10/014,143, for further detailed descriptions of the robotic and computer controller operation and associated operating algorithm.

As noted in FIG. 1, the drive unit 8 is remote from the operative site and is preferably positioned a distance away from the sterile field. The drive unit 8 is controlled by a computer system, part of the controller 9. The master station M may also be referred to as a user interface vis-a-vis the controller 9. Commands issued at the user interface are translated by the computer into an electronically driven motion in the drive unit 8. The surgical instrument, which is tethered to the drive unit through the cabling connections, produces the desired replicated motion. FIG. 1, of course, also illustrates an operating table 1 upon which the patient P is placed.

FIG. 1 illustrates both a flexible system and a rigid system. Only one drive unit is depicted it being understood that there is also a drive unit associated with the rigid instrument system such as shown in FIG. 4. Each of the drive units is controlled from cabling that couples from the controller. This is electrical cabling that drives corresponding motors in each drive unit.

Thus, the controller couples between the master station M and the slave station S and is operated in accordance with a computer algorithm. The controller receives a command from the input device 3 and controls the movement of the surgical instrument so as to replicate the input
manipulation. The controller may also receive commands from the master station for controlling instrument interchange.

[0044] With further reference to FIG. 1, associated with the patient P is the surgical instrument 14, which in the illustrated embodiment actually comprises two separate instruments one rigid and one flexible, along with an endoscope E. The endoscope includes a camera to remotely view the operative site. The camera may be mounted on the distal end of the instrument insert, or may be positioned away from the site to provide additional perspective on the surgical operation. In certain situations, it may be desirable to provide the endoscope through an opening other than the one used by the rigid surgical instrument. In this regard, in FIG. 1 there are shown two for accommodating the rigid surgical instrument and the endoscope, and the third accommodates the flexible instrument through a natural body orifice. A drape is also shown.

[0045] The viewing endoscope may also be formed integral with the instrument whether it be a rigid instrument or a flexible instrument. The optics and camera may be mounted directly on the distal part of the instrument such as at or adjacent the end effector. In particular, with respect to a flexible instrument the optics and camera may be supported at the distal end of the instrument.

[0046] In FIG. 1, as indicated previously two separate instruments are depicted, a rigid instrument system 14 and a flexible instrument system 500. In the rigid instrument system there is an instrument insert that carries at its distal end an end effector 18A entering the anatomy through a small incision. This may be for the purpose of providing access to the area about the bowel or bladder, for example. In the flexible instrument system there is a flexible and bendable instrument section terminating at the end effector 500A, and entering the anatomy, for example, through a natural body orifice such as through the anus in the case of a bowel procedure.

[0047] An end effector is usually associated with each of the instrument systems. In FIG. 1 this is illustrated by the end effectors 18A and 500A. These can take on a variety of different form such as scissors, graspers or needle drivers. Both of the medical instrument members comprise active work elements at respective member working ends and are usually disposed at opposite sides of an anatomic wall. By “active”, reference is made to end effectors that are useable in performing a surgical procedure or application and that are capable of being manipulated from a master station such as from a surgeon controlled input device.

[0048] The instrument system 14 is generally comprised of two basic components, including a surgical adaptor or guide 15 and an instrument insert 16. FIG. 1 illustrates the surgical adaptor 15, which is comprised primarily of the guide tube 24, but also includes a mechanical interface that interfaces with a corresponding mechanical interface of the instrument itself. In FIG. 1, the instrument 14 is not clearly illustrated but extends through the guide tube 24. The instrument 14 carries at its distal end the instrument member or insert. The surgical adaptor 15 is basically a passive mechanical device, driven by the attached cable array.

[0049] In FIG. 1 there is illustrated cabling that couples from the instrument 14 to the drive unit. The cabling 22 is preferably detachable from the drive unit. Furthermore, the surgical adaptor 15 may be of relatively simple construction. It may thus be designed for particular surgical applications such as abdominal, cardiac, spinal, arthroscopic, sinus, neural, etc. As indicated previously, the instrument 14 couples to the adaptor 15 and essentially provides a means for exchanging the instrument tools. The tools may include, for example, forceps, scissors, needle drivers, electrocautery etc. Other tool interchanges are also shown in further drawings herein.

[0050] Referring still to FIG. 1, the surgical system 10 includes a surgeon’s interface 11, computation system or controller 9, drive unit 8 and the surgical instrument 14. The surgical system 10, as mentioned previously, is comprised of an adaptor or guide 15 and the instrument insert 16. The system is used by positioning the instrument, which is inserted through the surgical adaptor or guide 15. During use, a surgeon may manipulate the input device 3 at the surgeon’s interface 11, to affect desired motion of the distal end of the instrument within the patient. The movement of the handle or hand assembly at input device 3 is interpreted by the controller 9 to control the movement of the guide tube 24, instrument, and, when an articulating instrument is used, the end effector or tool 18A. Also, movements at the master station may control instrument exchange.

[0051] The surgical instrument 14, along with the guide tube 24 is mounted on a rigid post 19 which is illustrated in FIG. 1 as removable affixed to the surgical table T. This mounting arrangement permits the instrument to remain fixed relative to the patient even if the table is repositioned. As indicated previously, connecting between the surgical instrument 14 and the drive units 8, are cabling. These include two mechanical cable-in-conduit bundles. These cable bundles may terminate at two connection modules, not illustrated in FIG. 1, which removable attach to the rigid instrument drive unit 8. Although two cable bundles are described here, it is to be understood that more or fewer cable bundles may be used. Also, the drive unit 8 is preferably located outside the sterile field, although it may be draped with a sterile barrier so that it may be operated within the sterile field.

[0052] In the preferred technique for setting up the system, and with reference to FIG. 1, the surgical instrument 14 is inserted into the patient through an incision or opening. The instrument 14 is then mounted to the rigid post 19 using a mounting bracket. The cable bundle or bundles are then passed away from the operative area to the drive unit. The connection modules of the cable bundles are then engaged into the drive unit. The separate instrument members of instrument 14 are then selectively passed through the guide tube 24. This action is in accordance with the interchangeable instrument concepts also described herein.

[0053] The instrument 14 is controlled by the input device 3, which is be manipulated by the surgeon. Movement of the hand assembly produces proportional movement of the instrument 14 through the coordinating action of the controller 9. It is typical for the movement of a single hand control to control movement of a single instrument. However, FIG. 1 shows a second input device that is used to control an additional instrument. Accordingly, in FIG. 1 two input devices are illustrated and two corresponding instruments. These input devices are usually for left and right hand.
control by the surgeon. Many other forms of input device control may also be used. For example, instead of finger graspers a joystick arrangement may be used.

[0054] The surgeon’s interface 11 is in electrical communication with the controller 9. This electrical control is primarily by way of the cabling 6 illustrated in FIG. 1 coupling from the bottom of the master assembly 7. Cabling 6 also couples from the controller 9 to the actuation or drive units. This cabling 6 is electrical cabling. Each of the actuation or drive units, however, is in mechanical communication with the corresponding instrument. The mechanical communication with the instrument allows the electromechanical components to be removed from the operative region, and preferably from the sterile field. The surgical instrument provides a number of independent motions, or degrees-of-freedom, when an articulating type instrument such as a tool, gripper, etc. is used. These degrees-of-freedom are provided by both the guide tube 24 and the instrument insert.

[0055] FIG. 1 shows primarily the overall surgical system. FIGS. 15-17 show further details particularly of the interchangeable instrument concepts as applied to this system. The rigid instrument part of the system is adapted to provide seven degrees-of-freedom when an articulating tool is used such as the tool 18A shown in FIG. 1. Three of the degrees-of-freedom are provided by motions of the adaptor 15, while four degrees-of-freedom may be provided by motions of the instrument. As will be described in detail later, the adaptor is remotely controllable so that it pivots, translates linearly, and has its guide tube rotate. The instrument insert also rotates (via rotation of the instrument driver), pivots at its wrist, and has two jaw motions at the tool.

[0056] Now, mention has been made of bowel and bladder procedures illustrated schematically in FIG. 2. This shows the two separately controlled instruments including rigid instrument system 14 that may be engaged laparoscopically through a small incision, and flexible instrument system 500 that may be engaged through the anus in the case of a bowel procedure or the urethra in the case of a bladder procedure. FIG. 2 also represents the respective end effectors 18A and endoscope VE directed at the operative site where the end effectors are acting.

[0058] Reference is now made to FIG. 3A showing a next step in the suturing procedure. The needle 19A has now passed through the vessel wall 20A. The suture 19B is attached to the end of the needle 19A, as illustrated. In FIG. 3A there is illustrated a viewing endoscope 19C that is attached to the instrument 18 just proximal of the end effector 18A.

[0059] In FIG. 3B the needle 19A is shown in the next step with the suture 19B having passed through the anatomic wall 20A. In this arrangement the viewing endoscope 19C is shown secured to the chest wall 19E. There may be provided a clamp 19D, or the like for holding the viewing endoscope in place and in a good viewing location for the surgical procedure that is being performed. In both FIGS. 3A and 3B the instrument system 500 is within the lumen 20C, while the instrument system 14 is outside the lumen 20C. The instrument systems 500 within the lumen are usually of the flexible type so as to be able to maneuver through an anatomic body part. The instrument system outside the lumen is illustrated as being of the rigid type but could also be of the flexible type.

[0060] FIG. 3C shows the use of another dual instrument system that is adapted for intraluminal/extraluminal positioning. This particular arrangement is for sewing between two separate vessels V1 and V2. This procedure may be used in a variety of different types of operations in which it is desirable to secure together two vessels or lumens, end-to-end. For this purpose there are provided two instrument systems, both of which are preferably robotically controlled from a master station input device. The control of the two systems may be under direct surgeon control such as from an input device manipulated by the surgeon, or, alternatively the systems may be automatically controlled so that once a sequence is initiated the ensuing steps are performed automatically. For example in a sewing procedure it may be desirable to position the instrument systems and, once positioned, it may be desirable to initiate a sequence of suturing steps or stitches so that the suturing occurs essentially automatically, with little or no surgeon intervention except for safety concerns.

[0061] Now, in FIG. 3C there is illustrated a dual instrument system that includes an internally disposed system 150, and an externally disposed system 160. The system 150 is usually of the flexible type as the instrument shaft has to negotiate a vessel or lumen that typically has non-straight portions. The instrument system 160, on the other hand, may be flexible or rigid, but would usually be rigid as it would enter the anatomy through an incision or percutaneously. In FIG. 3C the instrument systems together define a sewing system including, on the instrument system 150 a hook end effector 152, and on the instrument system 160 a needle end effector 162. Together these instrument systems are adapted to be operated in unison and usually in an automatic manner, although the sewing steps can also be performed under manual control of the surgeon from a master station.

[0062] The combination of the instrument systems 150 and 160 provide a sewing technique. The system 150 with its hook end effector 152 cooperates with the needle end effector 162 supported by the instrument system 160. This arrangement may be used to provide a chain stitch. Both of the end effectors are controllable with multiple degrees of freedom. Thus, if the systems are used under manual robotic
control the hook end effector 152 is moved in unison with the needle end effector 162 to provide the stitch 164. The needle end effector 162 is adapted to reciprocate relative to its presser foot 166. At the beginning of each stitch, the needle end effector 160 pulls a loop of suture material through the tissue. The hook end effector 150 moves in synchronism with the needle end effector 160 and grabs the loop of suture material before the needle end effector 160 pulls up. The instrument system proceed about the vessel portions and FIG. 3D shows the final stitch 164 that attaches the vessels or lumens together, end-to-end.

[0063] In connection with the systems shown in FIGS. 3C and 3D these instrument systems may also be controlled automatically and under computer control. In that case, once the instrument systems are in place, sensors associated with each instrument system detects the relative position between them. Then the computer at the controller that is disposed between master and slave stations, controls the instrument systems in unison to perform the stitching action. In other words the computer controls the action of the needle end effector and hook end effector to perform the stitch such as a chain stitch.

[0064] In the arrangement shown in FIGS. 3C and 3D the needle end effector is shown outside the lumen while the hook end effector is shown inside the lumen. In an alternate embodiment the positions of the instruments may be interchanged so the hook end effector is outside the lumen and the needle end effector is inside the lumen. The positioning between the end effectors can be controlled by sensing electromagnetic signals associated with sensors associated with each instrument system. The stitching sequences described can provide a variety of different stitch patterns. Inversion or eversion of sewed edges can be provided depending upon the particular surgical procedure being performed. For example, for cardiac procedures a slight inversion of the stitch is desired.

[0065] FIG. 3E illustrates a surgical procedure in the stomach using dual instruments, a flexible instrument passing into the stomach and either a rigid or flexible instrument outside the stomach wall. FIG. 3F schematically shows the end of the sewing or suturing technique at the stomach wall. The flexible instrument system 160A passes through the esophagus 167 entering initially through the patient's mouth. The outlet from the stomach is at the duodenum 168. This flexible instrument system is illustrated as having an operative segment O controlled by the surgeon in a telebotic manner to control bending at that segment for guidance of the distal end effector 160. An outside instrument system 150 is also illustrated which may be either a flexible or rigid instrument system. This is illustrated in FIG. 3E by system 150A carrying the end effector 150. In FIGS. 3E and 3F the end effectors may be the same as shown in FIGS. 3C and 3D used in performing a sewing or suturing operation. The instrument systems are controlled to perform the sewing or suturing action forming stitches 170 as illustrated in FIG. 3F. This stitching action closes the hole 169.

[0066] FIGS. 3E and 3D illustrate a surgical procedure on the stomach 165 particularly at the stomach wall 171. An ulcerated hole 169 is disclosed and it is the purpose of the instrument system shown to close up this hole by means of a sewing or suturing technique employing the instrument systems 150A and 160A. The procedure shown in FIGS. 3E and 3F can be performed manually from the master station or can be performed automatically under computer control initiated from the master station. The same or a similar procedure can also be used for gastric ulcers or for repairing a bowel wall defect.

[0067] FIG. 3G shows still another technique that can be practiced with the instrument systems described herein. In FIG. 3G the same reference characters are used to identify similar components as previously described in connection with FIGS. 3C and 3D. In this instance an object is being stitched within the body vessel 174. The object may be, for example, a stent 173 that is being secure or re-secured within the vessel walls. For this purpose in FIG. 3G there is illustrated the instrument systems 150A and 160A. Usually the instrument system 150A is flexible as it has to conform to the shape and contour of the inside of the vessel or lumen. The instrument systems 150A and 160A carry respective end effectors 150 and 160. These may be the same type end effectors described in connection with FIGS. 3C and 3D. FIG. 3G shows the stitching being completed at 175 at one end of the stent 173, and further shows the instrument systems in action at the other end of the stent securing the other end thereof by means of the illustrated instrument systems 150A and 160A.

[0068] In FIG. 3G the instrument system 150A may enter the anatomy through a lumen from a natural body orifice, or percutaneously. The instrument system 160A may be positioned at the lumen via an incision at a convenient location proximal to the operative site. The stitching action may be direct surgeon controlled my manipulation at a master station or can be used under automatic control. In FIG. 3G the securing may be for a newly placed object or can be used to repair an existing object. For example, the technique explained can be used for AAA stent failures.

[0069] Refer now to FIGS. 3H through 3J for an illustration of another surgical procedure that can be performed using the present inventive techniques. This example relates to the attachment of one vessel or lumen 177 to another vessel or lumen 178. This is a technique that can be used, for example, in performing a cardiac by-pass. In the illustrated steps the same instrument systems may be employed as previously discussed in connection with earlier embodiments that are described herein. This may include both flexible and rigid systems. Furthermore it is noted in this particular procedure that more than two instrument systems are employed. For example, refer to FIG. 3I where three instrument systems are shown, two positioned within respective lumens and one positioned outside the lumens.

[0070] FIG. 3H shows the lumen or vessel 178 to which the vessel or lumen 177 is to be attached. This illustrates the first step in the procedure of positioning the lumen 177 by means of the instrument system 180 that is dispose within the lumen 177. The instrument system 180 may carry a balloon 181 for example, that is inflated to hold the lumen 177 in place. The instrument system 180 may then be advanced to position the lumen 177 toward the position illustrated in FIG. 3I. The control of movement of the instrument system 180 may be by means of servo control from a master station input device. In this procedure, as well as other procedures described herein a viewing endoscope is used to assist in the positioning of instrument systems.

[0071] FIG. 3I now shows the next step in the procedure of attaching the tapered end of the vessel 177 to the side wall
of the vessel 178. For this purpose there is provided the previously described instrument systems 150A and 160A. These instrument systems are used to sew or suture about the open end of the vessel 177 to attach it to the side wall of the vessel 178. This sewing or suturing step is performed with the use and control of the end effectors 150 and 160. In FIG. 31 it noted that the instrument system 180 may be kept in place during this step to hold the vessel or lumen 177 against the vessel or lumen 178 to assure accurate attachment. At least part of the propulsion may be performed automatically, particularly the sewing or suturing technique.

[0072] After the step illustrated in FIG. 31 is completed then an opening is to be cut in the sidewall of lumen 178 to allow fluid flow between lumens. This is illustrated in FIG. 31, where additional instrument systems are now employed. One instrument system 182 may carry a cutting blade to perform the opening of the sidewall in the lumen 178. In the other lumen 178 there is disposed the instrument system 183 that carries a balloon 184 that is meant to hold the sidewall in place as the cutting operation is performed. For the purpose of illustration only one balloon id shown in FIG. 31, however, instead a pair of balloons may be used, one positioned on either side of the opening so that there is no interference between the cutting instrument and the supporting balloons.

[0073] Refer now to another use of the concepts of the invention illustrated in FIG. 3K.

[0074] This illustrates a surgical procedure that is performed in the bladder 185. FIG. 3K shows one instrument system 160A passing through the urethra 188 into the interior of the bladder. This is the instrument system 160A carrying the needle end effector 160. FIG. 3K also illustrates the other instrument system 150A carrying the hooked end effector 150. Both of these instrument systems are shown in relative proximity to each other and can be used to perform any one of a number of different procedures. For example, the instrument systems may be used to close the sphincter at the base of the ureter tube 186 that couples to the kidney 187.

[0075] FIG. 3L is a further illustration of the use of the instrument systems of the invention in closing the sphincter leading into the stomach 190 at the gastro-esophageal juncture. This is a procedure that is useful to reduce acid reflux that can occur in some patients. By reducing the size of the port at that point acids from the stomach are impeded from backing up into the esophagus. Thus, in FIG. 3L the aforementioned instrument systems 150A and 160A are used to perform a sewing or suturing operation so as to constrict the sphincter at the area 192 illustrated in FIG. 3L. The instrument system 150A carries the hook end effector 150 while the instrument system 160A carries the needle end effector 160. Both the instrument systems may be operated in the same manner as described previously in connection with other procedures that have been described herein.

[0076] FIG. 4 is an exploded perspective view of another version of the cable drive mechanism and tool. FIG. 5 is a top plan view of the rigid instrument insert itself. FIG. 4 is an exploded perspective view of the cable drive mechanism and instrument illustrating the de-coupling concepts at the slave station S.A section of the surgical tabletop T which supports the rigid post 19 is shown. The drive unit 8 is supported from the side of the tabletop by an L-shaped brace 210 that carries an attaching member 212. The brace 210 is suitably secured to the table T. The drive unit 8 is secured to the attaching member 212 by means of a clamp 214. Similarly, the rigid support rod 19 is secured to the attaching member 212 by means of another clamping mechanism 216.

[0077] Also in FIG. 4 the instrument 14 is shown detached from (or not yet attached to) support post 19 at bracket 25. The instrument 14 along with cables 21 and 22 and light-weight housing section 856 provide a relatively small and lightweight decoupleable slave unit that is readily manually engageable (insertable) into the patient at the guide tube 24.

[0078] After insertion, the instrument assembly, with attached cables 21, 22 and housing 856, is attached to the support post 19 by means of the knob 26 engaging a threaded hole in base 452 of adapter 15. At the other end of the support post 19, bracket 216 has a knob 213 that is tightened when the support rod 19 is in the desired position. The support rod 19, at its vertical arm 19A, essentially moves up and down through the clamp 216. Similarly, the mounting bracket 25 can move along the horizontal arm 19B of the support rod to be secured at different positions therealong. A further clamp 214 supports and enables the drive unit 8 to be moved to different positions along the attaching member 212. FIG. 4 also shows the coupler 230 which is pivotally coupled from base piece 234 by means of the pivot pin 232. The coupler 230 is for engaging with and supporting the proximal end of the instrument insert 16.

[0079] The first housing section 855 also carries oppositely disposed thumb screws 875 (see FIG. 4). These may be threaded through flanges 876. When loosened, these set screws enable the second housing section 856 to engage with the first housing section 855. For this purpose, there is provided a set 878 illustrated in FIG. 4. Once the second housing section 856 is engaged with the first housing section 855, then the thumb screws 875 may be tightened to hold the two housing sections together, at the same time facilitating engagement between the coupler disks 862 and the coupler spindles 860.

[0080] As illustrated in FIG. 4, the two housing sections 855 and 856 are separable from each other so that the relatively compact slave unit can be engaged and disengaged from the motor array, particularly from the first housing section 855 that contains the motors 800. The first section 855, as described previously, contains the motors 800 and their corresponding coupler disks 862. In FIG. 4, the second housing section 856 primarily accommodates and supports the coupler spindles 860 and the cables extending from each of the spindles to the cable bundles 21 and 22 depicted in FIG. 4.

[0081] FIG. 4 also shows details of the adaptor including the carriage 226 supported on rails 224. The carriage 226 holds the base piece 234 that, in turn, supports the instrument insert. The coupler 230 of the adaptor provides mechanical drive to the instrument insert. The carriage and rails are pivoted at 225 to provide one degree of freedom, while the in and out motion of the carriage provides another degree of freedom to the instrument.

[0082] As shown in FIG. 5, each wheel of the instrument coupler 300 has two cables 376 that are affixed to the wheel and wrapped about opposite sides at its base. The lower cable rides over one of the filler pulleys or capstans (e.g.,
capstan 34), which routes the cables toward the center of the instrument stem 301. It is desirable to maintain the cables near the center of the instrument stem. The closer the cables are to the central axis of the stem, the less disturbance motion on the cables when the insert stem is rotated. The cables may then be routed through fixed-length plastic tubes that are affixed to the proximal end of the stem section 301 and the distal end of the stem section 302. The tubes maintain constant length pathways for the cables as they move within the instrument stem.

The instrument coupler 300 is also provided with a registration slot 350 at its distal end. The slot 350 engages with a registration pin 352 supported between the bars 270 and 272 of base piece 234. The coupler 300 is also provided with a clamping slot 355 on its proximal end for accommodating the threaded portion of the clamping knob 327 (on adapter coupler 230). The knob 327 affirmatively engages and interconnects the couplers 230 and 300.

In operation, once the surgeon has selected a particular instrument insert 16, it is inserted into the adapter 15. The proximal stem 301, having the distal stem 302 and the tool 18 at the distal end, extend through the adapter guide tube 24. FIG. 4 shows the tool 18 extending out of the guide tube 24 when the surgical instrument 16 is fully inserted into the adaptor 15. When it is fully inserted, the tab 281 on the axial wheel 306 engages with the mating detent 280 in pulley 279. Also, the registration slot 350 engages with the registration pin 352. Then the coupler 230 is pivoted over the base 300 of the instrument insert 16. As this pivoting occurs, the respective wheels of the coupler 230 and the coupler 300 interengage so that drive can occur from the coupler 230 to the insert 16. The knob 327 is secured down so that the two couplers 230 and 300 remain in fixed relative positions.

FIG. 6 is a perspective view of one embodiment of the flexible instrument system 500 illustrated in FIG. 1. FIG. 7 is an enlarged detailed perspective view of the end effector that may be used with the flexible instrument system. FIG. 1 depicts flexible instrument system 500 supported from support bracket 502, which extends to the operating table. Usually the support bracket is supported from the side of the operating table and may be adjustable in position relative to the operating table, to dispose system 500 in a convenient position over or relative to the patient. In one embodiment, bracket 502 is secured to the operating table at one end. The other end of bracket 502 supports the entire flexible instrument by means of a two-piece structure similar to that described in copending U.S. Provisional Applications Ser. No. 60/279,087 filed Mar. 27, 2001 the entire teachings of which are incorporated herein by reference. A knob may be provided on support base 504, not shown in FIG. 1. Once the support base 504 is fixed to the support bracket 502, then the flexible instrument system is maintained in a fixed position at base 504, providing a stable and steady structure during the medical procedure. Like the rigid system in FIG. 1, system 500 can be positioned at an acute angle with respect to the operating table or can be arranged at other convenient positions depending upon the surgical procedure being performed.

Flexible instrument system 500 illustrated in FIG. 6 comprises flexible instrument 510 having a shaft 528 extending to mechanically drivable mechanism 526, which interlocks with base (or receiver) 506. Base 506 is supported on carriage 508. Carriage 508, in turn, is adapted for linear translation and supported by elongated rails 512 and 514. Rails 512 and 514 terminate at one end via end piece 516 which provides further support. Support base 504 terminates rails 512 and 514 at their other end. Carriage 508 includes bearings or bushings 509 that support the carriage from rails 512 and 514.

Flexible instrument system 500 employs two separate cable bundles for mechanically driving the flexible instrument along rails 512 and 514. Pulley 521 (dotted outline), residing within carriage control module 520, receives a first pair of cables 518. Pulley 521 also receives a second set of cables, which run through carriage 508 to a further pulley 522 supported by end piece 516. The second set of cables controls the translational motion of carriage 508 and terminates at point 519.

FIG. 6 also shows a set of cables 524 for driving control elements, e.g. pulleys within receiver 506. These control elements move the shaft and the tool in several degrees-of-freedom. Arrow J1 indicates the linear translation via module 520. Rotational arrow J2 indicates rotation of flexible shaft 528 of flexible instrument 510 about the inner axis parallel with the shaft length. Arrow J3 represents the flexing or bending of flexible shaft 528 at controlled flexible segment 530. In this embodiment, flexible segment 530 is positioned directly adjacent tool 534 at the distal end of shaft 528. Arrow J4 represents the pivot action of a wrist joint, which links tool 534 to shaft 528, about axis 532. In this embodiment, tool 534 is exemplified as a grasper, and arrows J5 and J6 represent the opening and closing actions of the tool jaws. Motions indicated by arrows J2-J6 are controlled from cabling 524 originating at receiver 506.

FIG. 7 provides an enlarged perspective view of the distal end of shaft 528 including flexible segment 530 and tool 534. The segment 530 corresponds to the section 500 illustrated in FIG. 3, while the end effector 534 corresponds to the end effector 500. Illustrated in FIG. 3, tool 534 comprises upper grip or jaw 602 and lower grip or jaw 603, both supported from link 601. Base 600 is affixed to or integral with flexible shaft 528. Link 601 is rotatably connected to base 600 about axis 532. A pivot pin may be provided for this connection. Upper and lower jaws 602 and 603 are rotatably connected to link 601 about axis 536 and again, a pivot pin can provide this connection.

FIG. 7 shows eight cables at 538 extending through the hollow inside of shaft 528 for control of tool 534 and flexible segment 530. Two of these cables operate the bend of flexible segment 530, two cables operate one of the jaws 602, two cables operate the other of the jaws 603 and the last two cables operate the wrist action about the axis 532. All of these cables travel through the hollow shaft 528 and through appropriate holes in flexible segment 530 e.g. wire 525. As well as holes in base 600. Each of these pairs of cables operates in concert to open and close jaws, pivot about the wrist, and bend flexible segment 530.

One pair of cables travels through shaft 528 and through appropriate holes in the base 600, wrapping around a curved surface of the link 601 and then attaching to the link. Tension on this pair of cables rotates the link 601 along with the upper and lower grips or jaws 602 and 603 about axis 532.

Two other pairs of cables also extend through the shaft 528 and through holes in the base and then pass
between fixed posts 612. These posts constrain the cables to pass substantially through axis 532, which defines rotation of link 601. This construction essentially allows free rotation of link 601 with minimal length changes in the cables passing to jaws 602 and 603. Thus, the cables actuating jaws 602 and 603 are essentially decoupled from the motion of link 601 and are not affected by any rotation of link 601. Cables controlling jaw movement terminate on jaws 602 and 603. These cables permit independent operation of the jaws 602 and 603 in clockwise and counter-clockwise directions with respect to axis 536. A similar set of cables is present on the underside of the link 601 (not shown). Each of the jaws 602 and 603, as well as the link 601, may be constructed of metal. Alternatively, link 601 may be constructed of a hard plastic material. Base 600 may also be constructed of a plastic material and may be integral with shaft 528.

Bending of flexible segment 530 is provided via diametrically disposed slots 662, which define spaced ribs 664. Flexible segment 530 also has a longitudinally extending wall 665 through which a cable may extend, particularly for the operation of the tool. One of the pairs of cables of bundle 538 controlling flexible segment 530 terminates where base 600 interconnects with shaft 528. This pair of cables works in concert to cause bending as indicated by arrow J3, i.e., in a direction orthogonal to the pivoting provided at wrist axis 532. The flexible segment 530 may also be provided with additional degrees of freedom by controlling bending in two axes, direction J3 that is illustrated and a direction orthogonal thereto.

FIGS. 8 and 9 show different embodiments that can be used with either instrument but that are illustrated, in particular, for the rigid instrument system. FIG. 8 illustrates the construction of one form of a tool. FIG. 8 is a perspective view. The tool 18 is comprised of four members including a base 600, link 601, upper grip or jaw 602 and lower grip or jaw 603. The base 600 is affixed to the flexible stem section 302 (see FIG. 5). The flexible stem may be constructed of a ribbed plastic. This flexible section is used so that the instrument will readily bend through the curved part of the guide tube 24.

The link 601 is rotatably connected to the base 600 about axis 604. FIG. 8 illustrates a pivot pin 620 at axis 604. The upper and lower jaws 602 and 603 are rotatably connected by pivot pin 624 to the link 601 about axis 605, where 605 is essentially perpendicular to axis 604.

Six cables 606-611 actuate the four members 600-603 of the tool. Cable 606 travels through the insert stem (section 302) and through a hole in the base 600, wraps around curved surface 626 on link 601, and then attaches on link 601 at 630. Tension on cable 606 rotates the link 601, and attached upper and lower grips 602 and 603, about axis 604. Cable 607 provides the opposing action to cable 606, and goes through the same routing pathway, but on the opposite sides of the insert. Cable 607 may also attach to link 601 generally at 630.

Cables 608 and 610 also travel through the stem 301, 302 and through holes in the base 600. The cables 608 and 610 then pass between two fixed posts 612. These posts constrain the cables to pass substantially through the axis 604, which defines rotation of the link 601. This construction essentially allows free rotation of the link 601 with minimal length changes in cables 608-611. In other words, the cables 608-611, which actuate the jaws 602 and 603, are essentially decoupled from the motion of link 601. Cables 608 and 610 pass over rounded sections and terminate on jaws 602 and 603, respectively. Tension on cables 608 and 610 rotate jaws 602 and 603 counter-clockwise about axis 605. Finally, as shown in FIG. 8, the cables 609 and 611 pass through the same routing pathway as cables 608 and 610, but on the opposite side of the instrument. These cables 609 and 611 provide the clockwise motion to jaws 602 and 603, respectively. At the jaws 602 and 603, as depicted in FIG. 8, the ends of cables 608-611 may be secured at 635, for example by the use of an adhesive such as epoxy glue, or the cables could be crimped to the jaws.

Reference is now made to FIG. 9. FIG. 9 is a side elevation view of a needle driver version of an end effector. This embodiment employs an over-center camming arrangement so that the jaw is not only closed, but is done so at a forced closure.

In FIG. 9, similar reference characters are employed with respect to the embodiment of FIG. 8. Thus, there is provided a base 600, a link 601, an upper jaw 650 and a lower jaw 652. The base 600 is affixed to the flexible stem section 302. Cabling 608-611 operate the end jaws. Linkages 654 and 656 provide the over-center camming operation. The two embodiments of FIGS. 8 and 9 employ a fixed wrist pivot. An alternate construction is illustrated in FIG. 10 in which there is provided, in place of a wrist pivot, a flexible or bending section. This type of bending section may be used with either flexible or rigid instrument systems.

FIG. 10 is a perspective view of an embodiment of a flexible or bendable wrist just proximal to the tool. FIG. 10 illustrates the manner in which the previously disclosed tools may be used with a flexible or bendable segment of the instrument shaft, whether used with a rigid shaft body or a flexible shaft body or combinations thereof. One of the advantages is that only a single cable needs to be coupled to the tool for actuation thereof. The pitch and yaw of the tool is controlled at the flexible section 100 shown in FIG. 10. This arrangement also lends itself to making the tool disposable or at the very least detachable from the instrument body such as for substitution of another tool. Because the construction becomes more simplified at the tip of the instrument, it makes it possible to construct a tool that is readily detachable from the instrument.

In FIG. 10 there is disclosed one embodiment of a tool, illustrated in conjunction with a flexible shaft or tube having a remotely controllable bending or flexing section 100. The medical instrument may comprise an elongated shaft, such as shaft section 110, having proximal and distal ends; and a tool, such as graspers 102 and 104, supported from the distal end of the elongated shaft and useable in performing a medical procedure on a subject. The tool is actuated preferably by a single tendon or cable that extends through the flexible section 100. In order to provide the pitch and yaw action at the tool, the bending or flexing section 100 is constructed so as to have orthogonal bending by using four cables separated at 90 degree intervals and by using a center support with ribs and slots about the entire periphery. Refer to the ribs 112 that define corresponding slots 114. The ribs define at each of their centers a center support passage 118 that has extending therethrough the cable 136. The
bending section 100 is at the end of tube section 110. The section 110 may be flexible itself, may be smooth as shown, or may be fluted.

[0102] The bending section 100 has alternating ridges 120 to provide universal bending. This version enables bending in orthogonal directions by means of four cables 106, 107, 116 and 117. The operation of cables 106 and 107 provides flexing in one degree-of-freedom while an added orthogonal degree-of-freedom is provided by operation of cables 116 and 117. Each of the cables 106, 107, 116, and 117 have at their terminating ends respective balls 106A, 107A, 116A, and 117A that may be held in corresponding recesses in a distal end wall 119 of the flexible section 100.

[0103] The bending section 100, as indicated previously, includes a series of spaced ribs 112 disposed, in parallel, with the plane of each rib extending orthogonal to the longitudinal axis of the section 100. At the proximal end of the bendable section an end rib connects to the shaft section 110, while at the distal end there is provided the distal end wall 119 that supports the ends of the cables. Each of the ribs 112 are held in spaced relationship by means of the alternating ridges 120. As depicted in FIG. 10 these ribs are identified as horizontal ribs 120A, alternating with vertical ribs 120B. This structure has been found to provide excellent support at the center passage for the actuating cable 136, while also providing enhanced flexibility in orthogonal directions of bending or flexing.

[0104] The grippers 102 and 104 are supported for opening and closing by means of a pivot pin 135 that extends along a pivot axis. These grippers may be supported in link 140. Refer to the exploded perspective view of FIG. 10 showing the pin 135, and grippers 102 and 104. The pin 135 may be supported at its ends in opposite sides of link 140.

[0105] Reference is now made to FIGS. 11-14 for an illustration of different end effector devices that can be used with the instrument systems described herein. FIG. 11 shows a clip applier 410. FIG. 12 shows a cutting jaw 420. FIG. 13 shows a device 430 for applying a solution or agent to an operative site. FIG. 14 shows a syringe type device 440 useable as an end effector.

[0106] The surgical robotic system, as illustrated in FIGS. 15-17, although preferably used to perform minimally invasive surgery, may also be used to perform other procedures as well, such as open or endoscopic surgical procedure. FIG. 15 is a perspective view at the slave station of the system of FIG. 1 illustrating the interchangeable instrument concepts as applied in a dual instrument system. FIG. 16 is a cross-sectional view through the storage chamber and as taken along line 16-16 of FIG. 15. FIG. 17 is a longitudinal cross-sectional view, as taken along line 17-17 of FIG. 15, and showing both a stored articulating instrument and a stored fluid dispensing.

[0107] Reference is now made to FIG. 15 which is a perspective view illustrating the instrument 14 and the adaptor 15 at the slave station S. This instrument system is secured in the manner illustrated in FIG. 1 to the rigid post 502 that supports the surgical instrument by way of a mounting bracket. FIG. 15 also shows several cables that may be separated into five sets for controlling different motions and actions at the slave station. These are individual cables of the aforementioned bundles 21 and 22 referred to in FIG. 4. FIG. 15 also illustrates the support yoke 220 that is secured to the mounting bracket 31, the pivot piece 222, and support rails 224 for the carriage 226. The rails are supported in end pieces 241 and 262 with the end piece 241 attached to the pivot piece 222. The pivot piece 222 pivots relative to the support yoke 220 about pivot pin 225. A base piece 234 is supported under the carriage 226 by means of the support post 228. The support post 228 in essence supports the entire instrument assembly, including the adaptor 15 and the instrument 14.

[0108] As indicated previously, the support yoke 220 is supported in a fixed position from the mounting bracket 31. The support yoke 220 may be considered as having an upper leg 236 and a lower leg 238. In the opening 239 between these legs 236 and 238 is arranged the pivot piece 222. Cabling extends into the support yoke 220. This is illustrated in FIG. 15 by the cable set 501. Associated with the pivot piece 222 and the carriage 226 are pulleys (not shown) that receive the cabling for control of two degrees-of-freedom. This control from the cable set 501 includes pivoting of the entire instrument assembly about the pivot pin 225. This action pivots the guide tube 24 essentially in a single plane. This pivoting is preferably about an incision of the patient which is placed directly under, and in line with, the pivot pin 225. Other cables of set 501 control the carriage 226 in a linear path in the direction of the arrow 227. See also the cables 229 extending between the carriage 226 and the end pieces 241 and 262. The carriage moves the instrument and guide tube back and forth in the direction of the operative site OS. Incidentally, in FIG. 15 the instrument is in its fully advanced state with the tool at the operative site OS.

[0109] The base piece 234 is the main support for the interchangeable instrument apparatus of the invention. The base piece 234 supports the guide tube 24, the instrument storage chamber 540, and the instrument driver 550. The instrument driver 550 is supported from another carriage, depicted in FIGS. 15 and 17 as the carriage 552, and that, in turn, is supported for translation on the carriage rails 554. The rails 554 are supported at opposite ends at end pieces 556 and 558, in a manner similar to the support for the other carriage 226. A support post 560 interconnects the carriage 552 with the instrument driver housing 570.

[0110] With further reference to FIG. 15, and as mentioned previously, there are a number of cable sets from bundles 21 and 22 coupled to and for controlling certain actions of the instrument system. Mention has been made of the cable set 501 for controlling instrument pivoting and translation, as previously explained. In addition, FIG. 15 depicts four other cable sets 503, 505, 507, and 509. Cable set 503 controls rotation of the guide tube 24. Cable set 505 controls the carriage 552, and, in turn, the extending and retracting of the instrument driver for instrument exchange. Cable set 507 controls rotation of the instrument through rotation of the instrument driver. Finally, cable set 509 controls the tool via the instrument driver and instrument. There is also one other set of control cables not specifically illustrated in FIG. 15 that controls the indexing motor 565, to be discussed in further detail later.

[0111] FIG. 17 shows a cross-sectional view through the interchangeable instrument portion of the overall instrument system. This clearly illustrates the internal cable and pulley arrangement for the various motion controls. There is a
pulley 301 driven from the cable set 503 that controls rotation of the guide tube 24. There is also a pulley 303 driven from cable set 505, along with a companion pulley 305 that provides control for the carriage 552. FIG. 17 also illustrates another pulley 307 driven from cable set 507, and for controlling the rotation of the instrument driver 550, and, in turn, the selected instrument.

[0112] FIG. 17 illustrates the guide tube 24 supported from the base piece 234. The guide tube 24 is hollow, has a curved distal end as illustrated in FIG. 15, and is adapted to receive the individual instruments or work sections 541 (articulating) or 590 (fluid-filled) disposed in the instrument storage chamber 540, as well as the instrument driver 550. Refer to FIG. 17 for an illustration of the instrument and instrument driver positioned in the guide tube 24. FIG. 17 shows the instrument driver 550 in its rest or disengaged position. The proximal end 24A of the guide tube 24 is supported in the base piece 234 by means of a pair of bearings 235 so that the guide tube 24 is free to rotate in the base piece 234. This rotation is controlled from the pulley 237 which is secured to the outer surface of the guide tube 24 by means of a set screw 231. The pulley 237 is controlled to rotate by means of the cable 310 that interouples the pulleys 301 and 237 and that is an extension of the cable 503. Thus, by means of the cable and pulley arrangement, and by means of the rotational support of the guide tube 24, the rotational position of the guide tube 24 is controlled from cable set 503. Of course, this controlled rotation is effected from the master station via the controller 9, as depicted in the system view of FIG. 1, and as a function of the movements made by the surgeon at the user interface 15.

[0113] As indicated before the proximal end 24A of the guide tube 24 is supported from the base piece 234. The distal end of the guide tube 24, which is adapted to extend through the patient incision, is disposed at the operative site OS illustrated about the instrument member 20 in FIG. 15, and where a medical or surgical procedure is to be performed. In the system shown in FIG. 15 the distal end of the guide tube 24 is curved at 24B. In this way by rotating the guide tube 24 about its longitudinal axis there is provided a further degree-of-freedom so as to place the distal end of the instrument at any position in three-dimensional space. The rotation of the guide tube 24 enables an orbiting of the instrument end about the axis of the guide tube 24. The guide tube 24 is preferably rigid and constructed of a metal such as aluminum.

[0114] FIG. 17 also illustrates a cross-section of the instrument storage chamber 540 including the storage magazine 549, and showing two of the six instrument passages 542 in the storage magazine 549. The instrument storage chamber may also be referred to herein as an instrument retainer. In FIG. 17 one of the fluid retaining instruments 590 is about to be engaged by the instrument driver 550. The other articulating type instrument 541 is in place (storage or rest position) in the instrument storage chamber 540, and out of the path of the instrument driver 550. The instrument 541 carries a gripper tool, but other instruments may also be carried such as a scissors. Because these instruments are adapted to pass to the guide tube 24 and be positioned at the distal end 24D thereof, the body 548 of each instrument is flexible so as to be able to curve with the curvature of the guide tube 24.

[0115] Although reference is made herein to the separate instrument and instrument driver, such as illustrated in FIG. 17, once they are engaged they function as a single piece instrument member. Accordingly reference is also made herein to the instrument driver 550 as a "driver section" of the overall one piece instrument member, and the instrument 541 or 590 as a "working section" of the instrument member. The instrument member has also been previously discussed as having a "coupling section" or "interface section", which is defined between the working section and the driver section where the cables interlock by means of an engaging hook arrangement. This is shown in FIG. 17 at 559.

[0116] The carriage 552 illustrated in FIG. 17 is moved linearly by the cables 555 that extend between pulleys 303 and 305. These cables attach to the carriage 552. The carriage movement is controlled from cable set 505. It is the movement of the carriage 552 that drives the instrument driver (driver section) 550. The instrument driver 550, in its rest or disengaged position, is supported between the instrument driver housing 570 and the wall 562 that is used for support of the instrument storage chamber 540. The instrument magazine 549 is rotationally supported by means of the axle or shaft 547, with the use of bushings or bearings, not shown. This support is between walls 562 and 563.

[0117] FIG. 17 shows the very distal end 525 of the instrument driver (transpoter) 550 supported at wall 562. In the rest position of the instrument driver 550 the driver is out of engagement with the instruments and the magazine 549, thus permitting rotation of the instrument storage chamber 540. The proximal end 526 of the instrument driver 550 is supported at the instrument driver housing 570. It may be rotationally supported by means of a bushing 527. The instrument driver 550 is supported for rotation, but rotation is only enabled once the driver has engaged the instrument and preferably is at the operative site. The rotation of the instrument driver 550 is controlled from cable set 507 by way of the pulley 307.

[0118] In FIG. 15 the cable set 509 is illustrated as controlling the instrument motions including tool actuation. These cables control a series of pulleys shown in FIG. 17 as pulleys 529. As indicated in FIG. 17 these pulleys control cable extending that extends through the instrument driver and the instrument for control of instrument and tool motions when articulating type tools are selected. The cables that are controlled from these pulleys may control three degrees-of-freedom of the instrument, including pivoting at the wrist and two for gripper action. The same engagement arrangement can be used in this second embodiment of the invention including the mating hook arrangement, interlocked at interface 559 when the instrument driver and instrument are engaged.

[0119] In one version of the invention a rotating member may be used for control of actuating rods. In the illustrated embodiment of the invention a different arrangement is used that includes a lead screw type of mechanism. This mechanism 591 is illustrated in FIG. 17 next to the pulleys 529. This mechanism includes a drive nut 593 having an internal threaded passage for receiving the actuating rod 592. The actuating rod 592 also has a threaded outer surface and further includes an elongated slot or keyway 594. An anti-rotation key 595 is fixed in position and is adapted to be received in the keyway 594. This engagement between the
key 595 and the actuating rod 592, prevents rotation of the actuating rod 592. However, the threaded engagement between the drive nut 593 and the outer threads of the actuating rod 592 enable linear (screw advance) translation of the actuating rod 592. This linear translation of the actuating rod initiates dispensing from the fluid-filled instrument by actuating the instrument member piston.

[0120] The drive nut 593 is journalized to the housing 570, but is free to rotate relative to the housing. A bearing 596 is provided to enable rotation of the drive nut 593 relative to the housing 570. The cable set 511 couples about the drive nut 593 to cause rotation thereof. Because the key 595 is fixed in position, then the actuating rod 592 can only move linearly in the direction of the arrow 597. The linear translation of the actuating rod 592 is transferred, via the driver 550, to the actuating rod of the instrument member. This action is, in turn, transferred to the dispensing piston of the syringe member 590. For further details refer to the pending applications referred to before and incorporated by reference herein.

[0121] FIG. 17 shows one fluid-filled instrument 590. The cable control via the cable set 511 can provide precise movement of the actuating rod 592 so that all or any portion of the liquid in the dispensing member can be ejected at the appropriate body site. If less than all the liquid is ejected then the instrument can be returned to the storage magazine in readiness for a subsequent use. By keeping track of the degrees of rotation of the drive nut 593, one can ascertain how much of the liquid has been dispensed and how much remains in the syringe member.

[0122] FIG. 18 is schematic diagram of the catheter system of the present invention as deployed through the urethra for a surgical procedure in the bladder. FIG. 18 provides a schematic cross-sectional diagram illustrating a surgical procedure where catheter K1 enters a natural body orifice, such as the urethra for carrying out procedures in, for example, the bladder. In FIG. 18 catheter K1 is shown extending into bladder B1. In this example, the computer controlled segment, identified as operative, bendable or flexible segment O in FIG. 18, is positioned at a more proximal section of catheter K1. Bladder B1, being an open cavity, does not have lumens leading from the urethra that would naturally guide a catheter towards any particular operative site. Upon entering bladder B1, catheter K1 can bend in any direction including the direction of the operative site. In this embodiment, because of the more proximal positioning of operative segment O, a surgeon can controllably bend the distal end of catheter K towards the operative site. In the embodiment shown in FIG. 18, the distal end of the catheter, labeled P1, can be rigid or be "passively" flexible, i.e. made of a flexible material and not necessarily controlled for flexure under remote computer control. FIG. 18 also shows another instrument system preferably a rigid instrument system including an instrument C extending through an incision D. The instrument shaft carries an end effector C1 that may be a set of jaws. Similarly, the bendable instrument K1 may carry an end effector C2. These instruments are coordinated in their action so that they can operate together in performing a surgical procedure. Refer also to the previous discussion regarding FIG. 3K.

[0123] Refer now to FIG. 19 for added details of the bladder procedure referenced in FIGS. 3K and 18. This drawing also shows the cross-section through the wall W1 of the bladder B1, illustrating the ureter tube T1 that extends through the muscle wall to the kidney. This also shows an inside instrument system 11 with a corresponding end effector, as well as an outside instrument system 12 that likewise carries an end effector. These end effectors may be for sewing or for other purposes depending upon the particular procedure that is to be performed. The inside instrument system is usually flexible, while the outside instrument system may be either flexible or rigid.

[0124] Reference to a rigid instrument system usually refers to an instrument in which there is a shaft that is primarily rigid and usually meant for insertion into the patient through a small incision such as a laparoscopic incision. However, rigid instruments may also be used to some extent within a natural body orifice. Flexible shaft instruments may be used through a natural body orifice, by percutaneous entry, through an incision or by other means for entry into the patient.

[0125] FIG. 20 shows still another instrument system that may be used for suturing, sewing or other surgical procedures in a body cavity or vessel such as in the cavity 193 illustrated. The instrument system 194 uses a single instrument arrangement that actually has two or more work areas. By way of example in FIG. 20 there is, at the very distal end of the instrument system 194, an active work element 195. This may be the same as the instrument end effector 160 illustrated in FIG. 3K or may be a set of jaws. In addition to the active work element 195 the instrument system is also provided with an intermediate work element 197. This is another end effector that is adapted to cooperate with the end effector 195 in performing a surgical procedure. For sewing the end effector 197 may be a hook end effector previously described, or it may be an anvil construction. The end effectors shown in FIG. 20 may also be of other types such as, but not limited to, graspers, needle drivers, cautering tools, scalpels, etc. The instrument system shown in FIG. 20 is simple in construction using only a single controlled instrument member. Preferably the shaft of the instrument system is curved back upon itself as illustrated at 198 in FIG. 20. This construction enables the one instrument system to be used for performing a complete surgical procedure such as passing a suture through a fold of tissue as illustrated in FIG. 20.

[0126] Another concept relates to arthroscopic procedures, but could also apply to other medical procedures. This relates to the use of a single flexible instrument that might be used in, for example, a knee operation through a single entry point, rather than present instrumentation that uses multiple instruments and associated multiple incisions. The procedures described herein are also advantageous in that they can be carried out without requiring open incisions, thus lessening recovery times.

[0127] The following are some of the additional features that characterize these inventions and relating to the use of multiple instruments, particularly multiple instruments of different types and adapted for different locations of access to anatomic parts of the body.

[0128] (A) The use of instruments intralumenally minimizes the number of incisions that have to be made in a particular procedure.

[0129] (B) The intralumenal instrument can be used as a “locator” to assist in locating the extralumenal instrument.
For example, one can locate the coronary vessel (often hidden by fat and muscle, and not on the heart surface) for anastomosis by means of the intraluminal instrument.

5. The robotic medical system of claim 1, wherein the each of the at least one electromechanical driver has a motor array.

6. The robotic medical system of claim 1, wherein the intraluminal medical instrument is flexible, and the extraluminal medical instrument is rigid.

7. The robotic medical system of claim 1, wherein both the intraluminal medical instrument and extraluminal medical instrument are flexible.

8. The robotic medical system of claim 1, wherein the intraluminal medical instrument is flexible and is configured for being introduced at the first region through a natural body orifice or percutaneously; while the extraluminal medical instrument is rigid and is configured for being introduced at the second region through a surgical opening or laparoscopically.

9. The robotic medical system of claim 1, wherein the first and second tools are suturing tools, and the at least one of the suturing procedure and the sewing procedure is a suturing procedure.

10. The robotic medical system of claim 9, wherein one of the first suturing tool and the second suturing tool has a needle, and another of the first suturing tool and the second suturing tool has a tissue grasper.

11. The robotic medical system of claim 10, wherein the tissue grasper is configured for grasping a fold of a wall of the anatomical vessel, and the needle is configured for passing a suture through the wall fold.

12. The robotic medical system of claim 1, wherein the first and second tools are sewing tools, and the at least one of the suturing procedure and the sewing procedure is a sewing procedure.

13. The robotic medical system of claim 12, wherein one of the first sewing tool and the second sewing tool has a needle, and another of the first sewing tool and the second sewing tool has a hook end effector that cooperates with the needle to perform the sewing procedure.

14. The robotic medical system of claim 13, wherein the one of the first sewing tool and the second sewing tool has a presser foot, and the needle is configured for reciprocating relative to the presser foot.

15. The robotic medical system of claim 13, wherein the needle is configured for pulling a loop of suture material through a wall of the anatomical vessel, and the hook end effector is configured for grabbing the loop of material before the needle pulls the loop of suture material through the anatomical vessel wall.

16. A method of performing a medical procedure on a patient, comprising:

   conveying control signals from a remote controller to a drive unit; and

   operating the drive unit in accordance with the control signals to advance a first medical instrument within an anatomical vessel of the patient, to advance a second medical instrument outside of the anatomical vessel, and to respectively actuate first and second tools located on the first and second medical instruments, in unison, to perform at least one of a suturing procedure and a sewing procedure on the anatomical vessel.
17. The method of claim 16, wherein the control signals are conveyed from the remote controller to the drive unit in response to user commands.

18. The method of claim 16, wherein the user commands are movements made at a user interface that correspond to movements of the first and second medical instruments.

19. The method of claim 16, wherein the first medical instrument is introduced within the patient through a natural body orifice or percutaneously, and the second medical instrument is introduced within the patient through a surgical opening or laparoscopically.

20. The method of claim 16, wherein the anatomical vessel is a blood vessel.

21. The method of claim 16, wherein the first and second tools are suturing tools, and the at least one of the suturing procedure and the sewing procedure is a suturing procedure.

22. The method of claim 21, wherein one of the first suturing tool and the second suturing tool has a needle, another of the first suturing tool and the second suturing tool has a tissue grasper, and the suturing procedure is performed by grasping a fold of the anatomical vessel using the grasper, and passing a suture through the fold using the needle.

23. The method of claim 16, wherein the first and second tools are sewing tools, and the at least one of the suturing procedure and the sewing procedure is a sewing procedure.

24. The method of claim 23, wherein one of the first sewing tool and the second sewing tool has a needle, another of the first sewing tool and the second sewing tool has a hook end effector, and the sewing procedure is performed by pulling a loop of suture material through a wall of the anatomical vessel using the needle, and grabbing the loop of suture material with the hook end effector before the needle pulls the loop of suture material through the anatomical vessel wall.

25. The method of claim 24, wherein the one of the first sewing tool and the second sewing tool has a presser foot, and the sewing procedure is further performed by reciprocating the needle relative to the presser foot.

26. The method of claim 16, wherein the at least one of a suturing procedure and a sewing procedure comprises securing the ends of two segments of the anatomical vessel together.

27. The method of claim 16, wherein the at least one of a suturing procedure and a sewing procedure comprises securing a stent to the anatomical vessel.

28. The method of claim 16, wherein the at least one of a suturing procedure and a sewing procedure comprises transversely securing another anatomical vessel to a side wall of the anatomical vessel.

29. The method of claim 16, wherein the at least one of a suturing procedure and a sewing procedure comprises constricting a sphincter located in the anatomical vessel.

30. The method of claim 29, wherein the anatomical vessel is a ureter, and the sphincter is located at the base of the ureter.

31. The method of claim 29, wherein the anatomical vessel is an esophagus, and the sphincter is located at a gastro-esophageal juncture.
