TITLE: Cleaning in Membrane Filtration Systems

FIELD OF THE INVENTION

The present invention relates to the backwashing of hollow permeable membranes used in membrane filtration systems and, in particular, to an improved method of backwashing and 5 cleaning the hollow permeable membranes.

BACKGROUND ART

Any discussion of the prior art throughout the specification should in no way be considered as an admission that such prior art is widely known or forms part of common general knowledge in the field.

10 Known backwash systems include those described in our earlier International Application No. WO93/02779.

During cleaning of membranes, cleaning solutions are often flowed through the membranes and their permeable walls to clean foulants from the membranes. Applying the cleaning solution under pressure assists the removal of foulants from the surface.

15 The typical known cleaning procedure for membranes involves cleaning the membranes in-situ. This procedure adds a set concentration of chemical, commonly 2% citric acid followed by 200 — 1000 ppm sodium hypochlorite, to the membrane in a solution of filtrate. This usually occurs at the start of the two hour cleaning period, after which the cleaning solution is filtered through the membrane and left to soak.

- 2 -

As the nature of membrane fouling varies according to feed quality and type, flux through the membrane and hours of operation, the amount and length of chemical cleaning required in each situation also varies. This often results in a one process fits all approach where a standard chemical cleaning stage is 5 applied regardless of the amount of fouling. This can lead to large amounts of cleaning solution being used unnecessarily with the effect of additional cost and environmental impact in disposing of the waste solution after cleaning is complete.

DISCLOSURE OF THE INVENTION

10 It is an object of the invention to overcome or at least ameliorate one or more of the disadvantages of the prior art or at least provide a useful alternative.

According to a first aspect, the present invention provides a method of cleaning permeable, hollow membranes in an arrangement of the type wherein a pressure differential is applied across the walls of the permeable, hollow 15 membranes immersed in a liquid suspension, said liquid suspension being applied to the outer surface of the porous hollow membranes to induce and sustain filtration through the membrane walls wherein:

(a) some of the liquid suspension passes through the walls of the 20 membranes to be drawn off as clarified liquid or permeate from the hollow membrane lumens, and

(b) at least some of the solids are retained on or in the hollow membranes or otherwise as suspended solids within the liquid surrounding the membranes,

the method of cleaning comprising the steps of:

- 3 -

- i) removing, at least partially, liquid from the filtrate side of the membrane;
- ii) removing, at least partially, liquid from the outer side of the membrane;
- 5 iii) applying a cleaning solution to the outer side of the membrane;
- iv) applying a pressure differential across said membrane wall to cause flow of said cleaning solution through said wall from the outer side of the membrane into the membrane lumen to at least partially fill said lumen with cleaning solution;
- 10 v) isolating the outer side of the membrane;
- vi) applying a pressurized gas to the filtrate side of the membrane wall to cause flow of the cleaning solution back to the outer side through the membrane wall;
- vii) accumulating the increased pressure developed on the outer side of the membrane as a result of said flow of cleaning solution;
- 15 viii) releasing the pressure applied by said pressurised gas to said filtrate side of the membrane wall to cause flow of said cleaning solution through said membrane from the outer side to the filtrate side under the effect of said accumulated pressure on the outer side of the membrane wall.

For preference the cleaning solution is a chemical cleaning solution.

Preferably, in step vi) gas, usually air, is applied such that the membrane lumen is substantially drained of cleaning solution. Preferably the pressure is accumulated in step vii) in a gas space provided on the outer side of the membrane wall or alternatively in a bladder arrangement.

- 4 -

The differential pressure of step iv) may be provided by applying gas pressure to the outer side of the membrane wall or by applying a vacuum to the filtrate side.

According to a further aspect the present invention provides a method of
5 cleaning permeable, hollow membranes in an arrangement of the type wherein
a pressure differential is applied across the walls of the permeable, hollow
membranes immersed in a liquid suspension, said liquid suspension being
applied to the outer surface of the porous hollow membranes to induce and
sustain filtration through the membrane walls wherein:

10 (a) some of the liquid suspension passes through the walls of the
membranes to be drawn off as clarified liquid or permeate from the
hollow membrane lumens, and
(b) at least some of the solids are retained on or in the hollow
membranes or otherwise as suspended solids within the liquid
15 surrounding the membranes,

the method of cleaning comprising the steps of;
i) applying a cleaning solution to one side of the membrane wall;
ii) applying a pressure differential across said membrane wall to
cause flow of said cleaning solution through said wall from said
20 one side of the membrane wall to the other side of the membrane
wall;
iii) applying a reverse pressure differential across said membrane
wall to cause flow of said cleaning solution through said wall from
said other side of the membrane wall back to said one side of the
membrane wall.
25

- 5 -

According to yet a further aspect the present invention provides a method of cleaning permeable, hollow membranes in an arrangement of the type wherein a pressure differential is applied across the walls of the permeable, hollow membranes immersed in a liquid suspension, said liquid suspension 5 being applied to the outer surface of the porous hollow membranes to induce and sustain filtration through the membrane walls wherein:

(a) some of the liquid suspension passes through the walls of the membranes to be drawn off as clarified liquid or permeate from the hollow membrane lumens, and

10 (b) at least some of the solids are retained on or in the hollow membranes or otherwise as suspended solids within the liquid surrounding the membranes,

the method of cleaning comprising the steps of;

i) removing, at least partially, liquid from the filtrate side of the 15 membrane;

ii) removing, at least partially, liquid from the outer side of the membrane;

iii) applying a cleaning solution to the outer side of the membrane;

iv) applying a pressure differential across said membrane wall to 20 cause flow of said cleaning solution through said wall from the outer side of the membrane into the membrane lumen to at least partially fill said lumen with cleaning solution;

v) applying a pressure differential across said membrane wall to cause flow of said cleaning solution through said wall from the

- 6 -

lumen side of the membrane back to the outer side of the membrane lumen.

Preferably the pressure differential in step v) is produced by applying a pressurized gas to the filtrate side of the membrane wall to cause flow of the 5 cleaning solution back to the outer side through the membrane wall.

The cleaning process can be repeated in cycles such that the cleaning solution is alternately moved from one side of the membrane to the other through the membrane wall.

The process can be applied to membranes submerged in an open vessel 10 as well as pressurized membrane filtration systems.

According to another aspect of the present invention there is provided a method of controlling a chemical clean of a membrane comprising:

measuring pH and/or membrane resistance of a membrane for at least a portion of said clean; and

15 ceasing said chemical clean when pH and/or membrane resistance attains a predetermined value.

According to another aspect of the present invention there is provided a method of controlling a chemical clean of a membrane comprising:

measuring pH and/or membrane resistance of a membrane for at least a 20 portion of said clean;

measuring elapsed time of the clean;

calculating a rate of change of pH with respect to time ($d\text{pH}/dt$) and/or a rate of change of membrane resistance ($d\text{R}/dt$) with respect to time; and

ceasing said chemical clean when $d\text{pH}/dt$ and/or $d\text{R}/dt$ attains a 25 predetermined value.

- 7 -

According to another aspect of the present invention there is provided a method of controlling the chemical cleaning of a filtration system comprising the steps of

- measuring membrane resistance of a membrane for at least a portion of
- 5 said clean;
- measuring elapsed time of the clean;
- calculating a rate of change of membrane resistance (dR/dt) with respect to time; and
- using dR/dt to calculate a duration for completion of the clean.

10 According to another aspect of the present invention there is provided a method of controlling a chemical clean of a membrane comprising:

- increasing the amount of chemical cleaning agent present during the clean;
- measuring membrane resistance of a membrane for at least a portion of
- 15 said clean;
- ceasing the increase in chemical cleaning agent when membrane resistance attains a predetermined value.

20 Preferably, the amount of cleaning agent is increased incrementally. For preference, the predetermined value approximates a steady-state value of membrane resistance. Preferably, the membranes are microfiltration or ultrafiltration type membranes.

According to another aspect of the present invention, there is provided a method of cleaning a permeable, hollow membrane, the permeable, hollow membrane comprising a wall, a filtrate side, and an outer side, the method comprising:

- 5 removing liquid from the filtrate side of the membrane;
- removing liquid from the outer side of the membrane; applying a chemical cleaning solution to the outer side of the membrane;
- creating a pressure differential across the membrane wall to flow the chemical cleaning solution through the membrane wall from the outer side of the membrane
- 10 into the filtrate side to at least partially fill the filtrate side with the chemical cleaning solution;
- isolating the outer side of the membrane; applying a pressurized gas to the filtrate side to flow the chemical cleaning solution back to the outer side through the membrane wall;
- 15 accumulating an increased pressure developed on the outer side of the membrane as a result of the flow of the chemical cleaning solution; and
- venting the pressurized gas applied from the filtrate side of the membrane to atmosphere to flow the chemical cleaning solution through the membrane wall from the outer side to the filtrate side under the effect of the accumulated pressure on the
- 20 outer side of the membrane.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of the invention will now be described, by way of example only, with reference to the accompanying drawings in which:

20 DESCRIPTION OF PREFERRED EMBODIMENTS

Referring to the Figures 1 to 7, there is shown a membrane module 5 having a plurality of hollow fibre membranes 6. The fibre membranes 6 have their lumens 7 closed at the lower end in a lower pot 8 and open at the upper end through upper pot 9. The module 5 is contained in a vessel 10 having a

- 11 -

controllable valve 11 for opening/closing the vessel 10 to atmosphere. Upper pot 8 is connected to a filtrate collection chamber 12 having a port 13.

One embodiment of the cleaning process according to the invention will now be described with reference to Figures 1 to 3. As best shown in Figures 1a 5 to 1c, liquid remaining in lumens 7 after filtration is drained while liquid remaining in the vessel 10 is also at least partially drained. The vessel 10 is then, at least partially, filled with cleaning solution 14 as best shown in Figure 1a. A differential pressure is then applied across the membrane walls 15, in this embodiment by applying a vacuum to port 13, so that the cleaning solution 14 is 10 drawn through the membrane walls 15 (as shown in Figure 1b) and up the membrane lumen 7 until it is, at least partially, filled with cleaning solution.

As shown in Figures 2a and 2b, the valve 11 is then closed to isolate the vessel 10 while pressurized gas is applied through port 13 to the cleaning solution filling the membrane lumen 7 and displaced through the membrane wall 15 until the lumen 7 is substantially drained of cleaning solution. With the vessel 10 isolated, the transfer of cleaning solution 14 through the membrane wall 15 to the outer side of the membrane 6 results in the pressure within the vessel to increase as the gas space 16 within the vessel 10 is compressed.

As shown in Figures 3a to 3c, the lumen side of the membranes are 20 vented to atmosphere. The accumulated pressure in the gas space 16 then forces the cleaning solution 14 to flow back through the membrane wall 15 as best shown in Figure 3b.

Figures 4a to 7b illustrate embodiments of the invention where a bladder arrangement may be used instead of the gas space 16 to accumulate pressure.

Referring to Figures 4a to 4c, the operation is similar to that shown in Figure 3a to 3c, however, in this embodiment when the lumen side of the membranes is vented to atmosphere through valve 17, the bladder 16 delivers pressure to the feed side of the vessel 10 forcing the cleaning solution 14 through the membrane wall 15 and along the membrane lumen 7 as best shown in Figures 4b and 4c.

Referring to Figures 5a and 5b, the pressurising of the lumen/filtrate side is shown. Pressurised gas is applied to the lumen/filtrate side of the membranes 6 by feeding pressurised gas through line 18 and valve 17 to port 13. The 10 pressurised gas causes the cleaning solution within the lumen 7 to flow through the membrane wall 15 to the outer side of the membrane resulting in the pressure within the vessel 10 increasing and being transferred to the bladder 16 connected to the vessel 10 through line 19 and valve 11.

Figures 6a to 6c show a similar arrangement to Figures 4a to 4c but in this 15 embodiment the gas pressure is applied to the vessel 10 from an external source, rather than the bladder 16, through line 19 and valve 11. Bladder 16 is used to accumulate pressure on the lumen side of the membranes 6 as shown in Figure 6a.

As shown in Figures 7a and 7b, when the reverse flow of cleaning solution 20 is required, the vessel 10 is vented to atmosphere through line 19 and valve 11 and bladder 16 releases accumulated pressure to the lumen side forcing the cleaning solution 14 within the lumens back through the lumen walls 15 (see Figure 7b).

Referring to Figures 8 and 9, an embodiment of the cleaning process 25 according to the invention is illustrated where the vessel 10 is open to

- 13 -

atmosphere. In this embodiment flow of cleaning solution through the membrane wall 15 is provided by alternately applying suction/vacuum or pressure to the lumen side of the membranes 6. The membrane module 5 is again immersed at least partially in chemical cleaning solution 14 and suction is applied to the open ends of the fibre membrane lumens 7. As best shown in Figure 8b, the cleaning solution 14 is drawn through the membrane wall 15 and into the fibre membrane lumen 7. The cleaning solution 14 is then drawn up through the lumen 7 until it is completely filled as shown in Figure 8c. As shown in Figures 9a and 9b, pressurized gas is then applied to the cleaning solution 14 filling the membrane lumen 7 and the cleaning solution is displaced through the membrane wall 15 as previously described.

The process illustrated in the embodiments can be repeated in cycles such that cleaning solution is alternatively moved from one side of the membrane wall 15 to the other. This flow of cleaning solution to and from the membrane lumens 7 and well as along their length results in an effective chemical clean of the membrane module 5.

Figure 10 shows the results of applying the cleaning regime according to the invention to a membrane module of the type where the vessel 10 is open to atmosphere. The cleaning process was performed as follows:

- 20 1. The membrane vessel was filled with filtrate via backfilling from the lumen side to the shell side, with simultaneous chlorine dosing into the filtrate line. The vessel filtrate level was about 30%, with a target volume of cleaning solution (NaOCl) of 30 mL.

- 14 -

2. The filtrate was then recirculated briefly through the system in order to ensure a well-mixed cleaning solution.

3. The lumens were then drained of liquid by 100 kPa air being applied to the filtrate line. This allowed the cleaning solution to diffuse through the pores and 5 down the fibre length, which raised the filtrate vessel level. This step may be ended when the liquid level stops rising.

4. The lumens were then filled with the cleaning solution by using vacuum air applied to the lumen side of the membranes. During this step the level in the filtrate tank dropped as the liquid was pulled into the fibre lumens. This step 10 may be ended when the liquid level stops falling.

5. The lumen fill and drain steps were repeated until contact time had reached 1800 seconds.

6. After 1800 seconds of cleaning solution contact, the vessel was topped up with feed. This allowed the remaining free chlorine in the cleaning solution to 15 contact with the part of the module that was exposed during the clean.

7. The system was then aerated to maximise contact of solution with module.

8. The tank was then drained and flushed with filtrate before returning to service.

The data graphed in Figure 10 shows a period when the cleaning regime 20 was performed once every 24 filtration hours for 4 days in succession, with the module operating at 1.7m3/hr with a 30 minute backwash interval. Chlorine in the form of sodium hypochlorite (NaOCl) was used, the average free chlorine

concentration during the clean being 100 ppm. Feed water turbidity was between 60 – 90 NTU throughout.

The data shown in Figure 10 illustrates the regular reduction in transmembrane pressure (TMP) flowing each clean.

5 One embodiment of the invention seeks to minimise the amount of chemical required by adding it incrementally to the membrane tank, whilst monitoring resistance through the membrane during a recirculation stage in the cleaning process. Chemical additions can cease when the further addition of chemical leads to change in the membrane resistance below a predetermined 10 level, hence minimising the amount of excess chemical agent used in the cleaning process.

The resistance value can be monitored during filtrate recirculation. Typically, during a standard cleaning procedure, the chemical cleaning solution is recirculated at the start of the clean only, followed by up to 48 hours of 15 soaking of the membranes. In the present embodiment, the chemical cleaning solution is recirculated for several minutes (for example - 3 minutes) every 15 – 30 minutes during the soak/aeration steps, allowing the membrane resistance to be measured periodically throughout the cleaning process.

When the change in resistance per 3 recirculations drops below a 20 predetermined value (for example -0.1) the cleaning process has recovered the maximum performance at that chemical concentration and further chemical agent is added. When the addition of further chemical agent effects the change in resistance by less than the predetermined value per 3 recirculations (for example - 0.1), no further recovery can be achieved and the cleaning 25 process can therefore be terminated immediately. Conversely, the cleaning

- 16 -

potential can be maximized by extending the cleaning process so that the change in resistance per 3 circulations is below a certain predetermined value. Figure 11 shows a graph of resistance value variation of the duration of the cleaning process for two different cleaning regimes using citric (CIP1) and 5 chlorine (CIP2) cleaning agents.

Referring to the graph shown in Figure 12, the volume of chemical agent begins around 100ml as shown at A resulted in a significant drop in membrane resistance. The amount of chemical agent was further increased as shown at B and C resulting in further decreases in membrane resistance. Once the volume 10 of chemical agent reached about 250ml, the membrane resistance change reached substantially a steady state as shown at D and further increases (E) in chemical agent had minimal effect. At this stage the volume of chemical agent added can be ceased without adversely affecting the cleaning process and recovery in transmembrane flow.

15 It will be appreciated that using the above measurements it is possible to determine a resistance profile during the cleaning process for a particular membrane arrangement or configuration. The resistance profile can then be used to predict the end of cleaning process time, half-life and reduce chemical use in simultaneous cleans of similar systems. The resistance profile may be 20 further used to determine whether chemicals are required to be added during the cleaning process with the type and amount of chemical being dependent on feed and foulant quality.

Typical cleaning solutions which may be used include acids, caustic solutions and oxidizing solutions (e.g. chlorine).

- 17 -

The invention may be embodied in a similar apparatus to that described in the aforementioned International Application No. WO93/02779 appropriately modified to operate in accordance with the inventive method.

CLAIMS

THE EMBODIMENTS OF THE INVENTION IN WHICH AN EXCLUSIVE PROPERTY OR PRIVILEGE IS CLAIMED ARE DEFINED AS FOLLOWS:

1. A method of cleaning a permeable, hollow membrane, the permeable, hollow membrane comprising a wall, a filtrate side, and an outer side, the method comprising:
 - 5 removing liquid from the filtrate side of the membrane;
 - removing liquid from the outer side of the membrane;
 - applying a chemical cleaning solution to the outer side of the membrane;
 - creating a pressure differential across the membrane wall to flow the chemical

10 cleaning solution through the membrane wall from the outer side of the membrane into the filtrate side to at least partially fill the filtrate side with the chemical cleaning solution;

15 isolating the outer side of the membrane;

applying a pressurized gas to the filtrate side to flow the chemical cleaning solution back to the outer side through the membrane wall;

20 accumulating an increased pressure developed on the outer side of the membrane as a result of the flow of the chemical cleaning solution; and

venting the pressurized gas applied from the filtrate side of the membrane to atmosphere to flow the chemical cleaning solution through the membrane wall from the outer side to the filtrate side under the effect of the accumulated pressure on the outer side of the membrane.

25

2. The method of claim 1, wherein applying the pressurized gas to the filtrate side comprises substantially draining the filtrate side of the chemical cleaning solution.

3. The method of claim 1, wherein accumulating the increased pressure comprises accumulating the increased pressure in a bladder arrangement.

30

4. The method of claim 1, wherein creating the pressure differential comprises applying gas pressure to the outer side of the membrane.

- 19 -

5. The method of claim 1, wherein creating the pressure differential comprises applying a vacuum to the filtrate side.
6. The method of claim 1, wherein the chemical cleaning solution comprises an
5 oxidizing solution.
7. The method of claim 6, wherein the chemical cleaning solution comprises chlorine.
