EP 0 585 276 B1

Description

This invention relates to the renovation of synthetic playing surfaces particularly, but not exclusively, sporting surfaces such as synthetic grass tennis courts, synthetic bowling greens and synthetic football and like playing fields, which generally include a layer of sand or other coarse particulate matter as part of their structural make up. The invention is primarily concerned with equipment for removing the coarse particulate matter, together with any entrained dirt, from the synthetic grass surface, separating the dirt from the sand, and returning the clean particulate matter to the synthetic grass surface. Another aspect of the invention concerns equipment for softening the layer of sand and/or other particulate matter in synthetic playing surfaces, and this aspect has particular applicability to sporting surfaces which are wet.

Since the invention is primarily concerned with the renovation of synthetic grass tennis courts, it will be described in that context. However, it will be readily apparent to the skilled addressee that the invention has much broader application than this and that such description is given merely by way of illustration.

DESCRIPTION OF THE PRIOR ART

Synthetic grass tennis courts typically comprise a synthetic mat surface from which extend tufts of simulated grass fibres of plastics material. Sand is layered over the mat surface filling the spaces between the tufts so that the tufts remain substantially erect and produce a flat surface which provides a ball rebound similar to a natural grass court surface.

In time, various environmental factors acting on such synthetic grass tennis courts necessitate cleaning or replacement of the sand. Cleaning may be done with high pressure water or with the use of nylon or wire brushes. High pressure water is disadvantageous in that it is a messy process and usually requires replacement of much of the sand and a considerable amount of releveling. Releveling is difficult with wet sand and is a laborious, time-consuming process. Nylon brushes are not very successful, particularly when the sand has become highly compacted, and wire brushes damage the synthetic mat and tufts.

DE-G-8804130 describes a machine for cleaning artificial grass surfaces which includes a rotating brush to dislodge particulates from the surface and "sweep" them into a collecting box where fine particulates are filtered out, and coarse particulates are redeposited onto the surface, by the action of a blower coupled to the collection box.

OBJECT OF THE INVENTION

It is therefore an object of the present invention to provide equipment for use in renovating synthetic grass tennis courts, for example, which does not have the disadvantages outlined above.

SUMMARY OF THE INVENTION

According to one aspect of the present invention, there is provided a device and method for dislodging, entraining and separating coarse and fine particulate matter layered on a synthetic playing surface as recited in claims 1 and 14 respectively. The device preferably comprises a plenum chamber having a compressed air inlet and at least one air outlet through which air can be expelled at an inclined angle against a playing surface so as to dislodge coarse and fine particulate matter layered thereon and to direct it into an adjacent manifold which extends above said plenum chamber, said manifold including a port located in its upper region through which the fine lightweight particulate matter is exhausted, and an outlet in a lower region by way of which the coarse heavyweight particulate matter is passed back to the playing surface.

The particulate dislodgment, entrainment and separating device is suitably arranged on a framework which permits easy manipulation over the surface to be treated. An arrangement for removing the separated lightweight matter and collecting it may also be included on such a framework. Most preferably, the framework is wheeled so that the device may be pushed or driven over the surface to be treated.

The plenum chamber is preferably an elongate chamber, most suitably of substantially tubular configuration which traverses the device from side to the other, that is, it is arranged such that it extends at approximately right angles to the direction in which the device is adapted to move or be propelled over the ground surface. The plenum chamber has at least one compressed air inlet, most preferably two - on opposing end walls thereof, and at least one outlet of relatively reduced size which effects an increase in the velocity of the air passing therethrough and which directs the air at an angle downwardly beneath the device against the particulate matter to be dislodged and entrained. The outlet may be one or more narrow slits, preferably extending in a straight line transversely of the device or, most preferably, a multiplicity of aligned pin holes. Suitably, the internal bore of each pin hole outlet is countersunk so that a venturi effect is produced by the air passing therethrough. The angle at which the outlet(s) is arranged is such as to provide maximum leverage on the particulate matter to be dislodged, whilst simultaneously directing the dislodged matter towards the inlet of the adjacent manifold. A suitable angle is between 30° and 75°, most preferably about 60° with respect to the synthetic surface. The number of outlets in the plenum chamber will ideally be maximized so that a large number of individual jets of fast moving air can be directed against the particulate surface, thereby optimising the dislodgment forces thereon. This is particularly important when the particulate matter has formed a hard crusty surface as is quite common in tennis court surfaces.

The manifold is suitably a hollow curvilinear duct of semi-cylindrical configuration with a longitudinal partic-

ulate inlet located adjacent the outlet(s) of the plenum chamber. The plenum chamber is suitably arranged coaxially with the duct so as to be closely spaced from the playing surface.

One or more baffle plates, preferably two, are arranged to partially enshroud the plenum chamber to prevent the coarse particulate matter from being carried into the manifold port and to direct the coarse particulate matter back onto the playing surface from which it has previously been uplifted. The baffle plates may take the form of curved plates arranged at spaced intervals above the plenum chamber.

In order to assist the circulation of the coarse and fine particulate matter in the manifold, a deflector can suitably be located in the region of the particulate inlet. The deflector may be a planar plate which is angled with respect to the adjacent playing surface so that particulate matter striking its surface is reflected upwardly into the manifold.

The longitudinal inlet of the manifold is suitably located in the front half or foremost section of the device and can, if need be, be covered with a grill or mesh of sufficient aperture to prevent entrainment of large pieces of debris which could conceivably block the manifold or at least impede the operation thereof. This, however, is not usually necessary.

The manifold may include a section adjacent the longitudinal inlet which extends upwardly in a substantially vertical direction and then curves in a constant radius of curvature through a horizontal section to a downwardly directed section which defines a coarse particulate matter outlet.

The manifold is ideally designed so that the wall adjacent the longitudinal inlet extends upwardly therefrom at a constant radius of curvature through a less curved region to a downwardly curved section which defines the outer wall at a coarse particulate outlet.

The coarse particulate matter outlet may be sufficiently larger than the manifold inlet to enable a drop in the velocity of the air as it passes from the manifold inlet to the outlet, thereby to spread the coarse particulate matter on the playing surface in a uniform layer.

The upper region of the manifold incorporates the port through which all lightweight matter is exhausted. The port is simply an opening about which a deflector or similar means can be arranged if necessary to prevent the coarse, particulate matter being sucked there-through. The coarse particulate matter is directed towards the outlet in the rear section of the manifold due to its heavier and bulkier nature.

In order to assist in the prevention of the coarse particulate matter blowing out from the sides of the device, between the bottom edge of the manifold and the ground surface, a skirt may be provided. This may take the form of a flat metal plate which extends outwardly from the manifold about its entire perimeter.

As previously mentioned, the particle dislodgment, separation and entrainment device is preferably supported on a wheeled framework. Such a framework is

preferably of tubular construction with thin gauge sheet metal walls for minimising the weight of the entire apparatus. A push/pull handle bar is suitably provided at waist-height for easy manipulation, and means enabling the manifold to be lowered close to the ground surface or for raising it when not in use are also included. Such means can comprise a set of pivotal linkages operated by a lever adjacent the push/pull handle.

When an arrangement is provided for removing the separated fine particulate matter and collecting it, this will suitably comprise a cyclone and chamber in combination with a filtering system. The cyclone is conveniently connected directly by way of a flexible duct to the port of the manifold. One form of cyclone comprises a cylinder with a conical head piece which is oriented in a vertical location on the wheeled framework between the manifold and the push/pull handle. An inlet is provided in the sidewall of the cyclone at an intermediate position, and internal plates direct the entrained fine particulate matter around the inner wall towards the bottom of the cyclone to a collection chamber directly beneath it. A filtering system is provided about an exhaust air outlet, or outlets, which is preferably located in the top of the cyclone. The filtering system may comprise one or more bags of filtering material supported from a framework which extends above the outlet(s). The filtering arrangement is designed to prevent any fine particulate matter blowing into the atmosphere while permitting the exhaust air to be expelled therethrough.

Compressed air used to charge the plenum chamber can be supplied from a portable compressor which is either carried by the support framework for the device or is supplied by a separate remote compressor. In this later context, a single compressed air line preferably supplies air to two separate lines connected to opposite ends of the plenum chamber, and a take-off line for driving the equipment.

According to a further aspect of the invention, there is provided a device and method for softening a synthetic playing surface which has compacted particulate matter layered thereon, as recited in claims 19 and 20. Preferably, the device comprises a plenum chamber having a compressed air inlet and at least one air outlet through which air can be expelled at high velocity at an inclined angle against a playing surface so as to dislodge the particulate matter layered thereon, uplifting the particulate matter into an adjacent manifold which extends above said plenum chamber, and drop said uplifted particulate matter back onto the playing surface in a non-compacted layer.

This device has been adapted particularly for synthetic surfaces which are wet and is therefore primarily used on winter sporting fields or those surfaces which are subjected to a lot of rain.

DESCRIPTION OF THE PREFERRED EMBODIMENT

A preferred embodiment of the invention will now be described with reference to the accompanying drawings, in which:-

Figure 1 is an end-on cross-sectional view of a device for dislodging, entraining and separating coarse and fine particulate matter according to the present invention;

Figure 2 is a view from below of the device depicted in Figure 1;

Figure 3 is an end-on perspective view of the device of Figure 1 supported on a framework and including a fine particle collecting chamber;

Figure 4 is a side view of the particle collecting chamber and filters; and

Figure 5 is a perspective view of a device for treating wet coarse particulate matter.

In all the figures, like reference numerals refer to like parts.

Referring firstly to Figures 1 and 2, the device, indicated generally at 1, comprises a plenum chamber 10, a manifold 11 and a port 12.

The plenum chamber 10 is a cylindrical tube which extends from one side of the device to the other in a transverse direction and has a compressed air inlet 9 at each end. It includes a multiplicity of pin hole outlets 13 through which compressed air can be directed at an inclined angle against the particulate ground surface 8, in the direction of arrow 14. This action loosens the particulate matter so that it can be uplifted at the manifold inlet 15 and be entrained in a stream of air which lifts it through the manifold as shown by the arrows. Deflector plate 16 assists in directing the particulate matter in an upward direction.

As the particulate matter is entrained upwardly, separation of the fine and coarse particles occurs due to their differences in momentum. The fine matter tends to be blown forwardly and upwardly for exhaustion through port 12, while the heavier coarser matter tends to lag behind to a certain extent and be deflected by baffles 17, 18 back on to the ground as shown by arrows 19, 20. The coarse particulate matter is, in fact laid back down in a similar array to that from which it was uplifted.

A lip 21 is provided at the perimeter of the manifold to prevent any particulate matter from being blown from the side of the manifold.

Referring to Figure 3, the device 1 is supported at the front end of a wheeled structure which includes means for collecting and storing the fine particulate matter as well as an air filtering arrangement and operation controls.

The wheeled structure comprises a panelled framework 30 having a jockey wheel 31 to enable steering with handle 33, and driven wheels 32. Wheels 32 propel the structure forward when compressed air motor 34 engages the wheels through the action of belt pulley 35

which is actuated by lever 36 through a system of levers culminating in linkage arm 37.

The interior of the wheeled structure holds the particulate collecting and storage equipment (see Figure 4 also) and is accessed through door 38. This equipment comprises a cyclone 40 into which is connected a flexible tube 41 extending from port 12 in the manifold of the device 1. The cyclone includes a number of baffles so that particulate matter in the air is separated and falls into bin 43. Filter socks 44 are supported from a disc 45 and encompass outlets 46 in the top of the cyclone. The filter socks remove all residual fine particulate matter from the air before it is exhausted to the atmosphere.

The plenum chamber is supplied with compressed air by way of high pressure lines 50, 51 which extend through the interior of the wheeled structure to the rear thereof. These lines are joined at a T-piece 52 to which air is admitted by way of control valve 53 and inlet 54. Inlet 54 joins to a separate mobile compressor (not illustrated).

A compressed air take-off compartment 55 is provided to supply air to the air motor 34.

Lever 56 functions to raise and lower the device 1 relative to the ground surface, through a series of linkages.

In operation, high pressure air from a compressor is admitted by way of inlet 54, T-piece 52 and lines 50, 51, to the plenum chamber. The device is lowered to the ground until it is closely spaced therefrom, by means of lever 56. The wheeled structure is then set in forward motion by pressurizing the air motor 34 with air and operating lever 36 so as to engage the belt on its pulley 35.

Air under pressure vents through the pin hole outlets 13 in the plenum chamber and impinges against the ground surface 8. Coarse and fine particulates matter is entrained within the air stream with the coarse matter being blown back onto the surface and the fine particulate matter being entrained in an air stream which exhausts into cyclone 40 by way of flexible tube 41. In the cyclone the air and dust are separated with the residual dust settling into bin 43 and about filter sock 44, and the air venting out through the filter sock 44. The device 40 described is particularly suitable for cleaning the sand of synthetic grass playing surfaces such as tennis courts and for cleaning the particulates from sand-free playing surfaces such as hockey fields.

The device depicted in Figure 5 is for softening up wet particulate material. It comprises a plenum chamber 60 having compressed air inlet 61, 62 and a plurality of pin hole outlets 63 arranged in a similar manner to those in the device depicted in Figure 1. The plenum chamber is located within a manifold 64 having a skirt 65. This device may be incorporated into the mobile arrangement of Figure 3 in place of the Figure 1 embodiment however since there is no outlet port the collection equipment is not utilized.

In operation, compressed air is directed at high velocity against a wet compacted surface containing particulate matter. The particulate matter is uplifted and then

dumped back onto the surface as the device is moved along, thereby producing a soft playing surface. This device is particularly suited to synthetic football and hock fields which have a sand filling.

A typical air pressure employed with both aspects of the invention is 375 cfm at 110 psi, and the diameter of the pin holes is 1.5 mm.

Claims

1. A device (1) for dislodging, entraining and separating coarse and fine particulate matter layered on a synthetic playing surface (8), the device comprising a manifold (11) for receiving said coarse and fine particulate matter displaced from the playing surface, said manifold including a port (12) located in its upper region through which the fine, lightweight particulate matter is exhausted, and an outlet in a lower region by way of which the coarse, heavy-weight particulate matter is passed back to the playing surface,

characterized in that the device further includes:

a plenum chamber (10), adjacent said manifold, having a compressed air inlet (9) and at least one air outlet (13) through which air can be expelled at an inclined angle directly onto the playing surface (8) so as to dislodge the coarse and fine particulate matter layered thereon and to direct it into the manifold (11) which extends above the plenum chamber (10).

2. A device as claimed in claim 1 wherein the plenum chamber (10) is of substantially tubular configuration and extends from one side of the device (1) to the other in a substantially horizontal disposition at right angles to the direction in which the device is adapted to be passed over the playing surface.
3. A device as claimed in claim 2, wherein there is an inlet (9) for compressed air at each end of the plenum chamber (10) and the outlet comprises a multiplicity of aligned pin holes (13) formed along a side of the plenum chamber.
4. A device as claimed in claim 3, wherein the pin holes (13) in the plenum chamber are aligned at an angle of approximately 60° with respect to the playing surface.
5. A device as claimed in any one of the preceding claims, wherein the manifold (11) is a hollow curvilinear duct with a longitudinal inlet (15) located adjacent the outlet of the plenum chamber (10).
6. A device as claimed in claim 5, wherein the manifold (11) includes a section adjacent the longitudinal inlet (15) which extends upwardly in a substantially vertical direction and then curves in a constant radius

of curvature through a horizontal section to a downwardly directed section which defines a coarse particulate matter outlet.

7. A device as claimed in claim 5, wherein the manifold includes a wall adjacent the longitudinal inlet which extends upwardly therefrom at a constant radius of curvature through a less curved region to a downwardly curved section which defines the outer wall at a coarse particulate outlet.
8. A device as claimed in claim 6 or 7, wherein the coarse particulate matter outlet is sufficiently larger than the manifold inlet (15) to enable a drop in the velocity of the air as it passes from the manifold inlet to the outlet, to thereby spread the coarse particulate matter on the playing surface in a uniform layer.
9. A device as claimed in any one of the preceding claims which includes at least one baffle plate (17,18) arranged to partially enshroud the plenum chamber (10) in order to prevent coarse particulate matter from being carried into the manifold port (12) and to direct the coarse particulate matter to the manifold outlet.
10. A device as claimed in any one of the preceding claims which is supported on a wheeled framework.
11. A device as claimed in claim 10 and including a chamber (43) for collecting the separated fine particulate matter, said chamber comprising a cyclone (40) connected at an inlet in its side wall to the port in the manifold, by a ducting (41).
12. A device as claimed in claim 11, and including a filtering arrangement (44) connected to an outlet at the top of the cyclone which permits air to vent to the atmosphere while retaining the fine particulate matter.
13. A device as claimed in any one of the preceding claims and including a compressed air source for supplying compressed air to the plenum chamber.
14. A method of dislodging, entraining and separating coarse and fine particulate matter layered on a synthetic playing surface (8), characterized by the steps of:
 - directing pressurized air directly onto and at an inclined angle to the playing surface to dislodge fine and coarse particulate matter therefrom;
 - entraining the fine and coarse particulate matter in a stream of air;
 - separating the fine and coarse particulate matter in said stream of air; and
 - returning the coarse particulate matter to the surface.

15. A method according to claim 14, wherein the directing step involves directing the pressurised air through a multiplicity of aligned pin holes (13).
16. A method according to claim 13 or 14, wherein the directing step involves directing the pressurised air at an angle of approximately 60° with respect to the surface.
17. A method according to any of the preceding claims, wherein the separating step involves passing the dislodged fine and coarse particulate matter through a manifold in which the separating step is carried out.
18. A method according to any of the preceding claims and including the further step of collecting the separated fine particulate matter.
19. A device for softening a synthetic playing surface which has compacted particulate matter layered thereon, the device comprising a manifold (64) for receiving particulate matter displaced from the playing surface, said manifold including an outlet in a lower region by way of which the particulate matter is passed back to the playing surface, characterized in that the device further includes:
 - a plenum chamber (60), adjacent said manifold (64), having a compressed air inlet (61,62) and at least one air outlet (63) through which air can be expelled at an inclined angle directly onto the playing surface so as to dislodge the particulate matter layered thereon and to direct it into the manifold (64) which extends above the plenum chamber (60).
20. A method of dislodging and entraining particulate matter layered on a synthetic playing surface (8), characterized by the steps of:
 - directing pressurized air directly onto and at an inclined angle to the playing surface to dislodge particulate matter therefrom;
 - entraining the particulate matter in a stream of air; and
 - returning the particulate matter to the surface with said stream of air.

Patentansprüche

1. Vorrichtung (1) zum Ablösen, Mitnehmen und Trennen von grob- und feinteiligem Material, das auf einem künstlichen Sportboden (8) aufgeschichtet ist, wobei die Vorrichtung ein Blasrohr (11) zum Aufnehmen des von dem Sportboden entfernten grob- und feinteiligen Materials aufweist und wobei das Blasrohr in seinem oberen Bereich eine Öffnung (12), durch die das leichtgewichtige feinteilige Material ausgeblasen wird, und in einem unteren Bereich einen Auslaß umfaßt, mittels dessen das schwergewichtige grobteilige Material auf den Sportboden zurückgeführt wird,

wichtige grobteilige Material auf den Sportboden zurückgeführt wird,

dadurch gekennzeichnet, daß die Vorrichtung weiterhin umfaßt:

einen angrenzend an das Blasrohr angeordneten Stoßdiffusor (10) mit einem Druckdufteinlaß (9) und mindestens einem Luftauslaß (13), durch den Luft unter einem Anstellwinkel direkt auf den Sportboden (8) ausstoßbar ist, um so das darauf aufgeschichtete grob- und feinteilige Material abzulösen und es in das Blasrohr (11) zu lenken, welches sich oberhalb des Stoßdiffusors (10) erstreckt.

2. Vorrichtung nach Anspruch 1, wobei der Stoßdiffusor (10) von im wesentlichen rohrförmigem Aufbau ist und sich von der einen Seite der Vorrichtung zu der anderen Seite der Vorrichtung in einer im wesentlichen horizontalen Anordnung rechtwinklig zu der Richtung erstreckt, in der vorgesehen ist, die Vorrichtung über den Sportboden zu verfahren.
3. Vorrichtung nach Anspruch 2, wobei an jedem Ende des Stoßdiffusors (10) ein Einlaß (9) für Druckluft vorgesehen ist und wobei der Auslaß eine Vielzahl von in einer Reihe ausgerichteten feinen Löchern (13) aufweist, die längs einer Seite des Stoßdiffusors ausgebildet sind.
4. Vorrichtung nach Anspruch 3, wobei die feinen Löcher (13) in dem Stoßdiffusor bezüglich des Sportbodens unter einem Winkel von etwa 60° in einer Reihe ausgerichtet sind.
5. Vorrichtung nach einem der voranstehenden Ansprüche, wobei das Blasrohr (11) ein gekrümmter Hohlkanal mit einem angrenzend an den Auslaß des Stoßdiffusors (10) angeordneten länglichen Einlaß (15) ist.
6. Vorrichtung nach Anspruch 5, wobei das Blasrohr (11) einen an den länglichen Einlaß (15) angrenzenden Bereich umfaßt, der sich im wesentlichen vertikal nach oben erstreckt und sich dann mit einem konstanten Krümmungsradius durch einen horizontalen Bereich bis in einen abwärts gerichteten Bereich krümmt, der einen Auslaß für das grobteilige Material definiert.
7. Vorrichtung nach Anspruch 5, wobei das Blasrohr (11) eine an den länglichen Einlaß (15) angrenzende Wandung umfaßt, die sich oberhalb davon mit einem konstanten Krümmungsradius durch einen weniger gekrümmten Bereich bis in einen abwärts gekrümmten Bereich erstreckt, der die Außenwandung an einem Auslaß für das grobteilige Material definiert.
8. Vorrichtung nach Anspruch 6 oder 7, wobei der Auslaß für das grobteilige Material ausreichend größer

- als der Einlaß (15) des Blasrohrs ist, um einen Abfall der Geschwindigkeit der Luft, wenn diese von dem Einlaß des Blasrohrs zu dem Auslaß gelangt, zu ermöglichen, um damit das grobteilige Material in einer gleichmäßigen Schicht auf dem Sportboden auszustreuen.
9. Vorrichtung nach einem der voranstehenden Ansprüche, die mindestens ein Leitblech (17, 18) umfaßt, welches derart angeordnet ist, daß es den Stoßdiffusor (10) teilweise umgibt, um grobteiliges Material davon abzuhalten, aus der Öffnung (12) des Blasrohrs ausgetragen zu werden, und um das grobteilige Material zu dem Auslaß des Blasrohrs zu lenken.
 10. Vorrichtung nach einem der voranstehenden Ansprüche, die an einem Gestell mit Rädern gelagert ist.
 11. Vorrichtung nach Anspruch 10 und die eine Kammer zum Sammeln des abgetrennten feinteiligen Materials umfaßt, wobei diese Kammer einen Fliehkraftabscheider (40) aufweist, der mit einem Einlaß in seiner Seitenwandung über eine Leitung (41) an die Öffnung in dem Blasrohr angeschlossen ist.
 12. Vorrichtung nach Anspruch 11 und die eine an einen Auslaß an der Oberseite des Fliehkraftabscheiders angeschlossene Filteranordnung (44) umfaßt, die es Luft erlaubt, in die Atmosphäre zu entweichen, während sie das feinteilige Material zurückhält.
 13. Vorrichtung nach einem der voranstehenden Ansprüche und die eine Druckluftquelle zum Versorgen des Stoßdiffusors mit Druckluft umfaßt.
 14. Verfahren zum Ablösen, Mitnehmen und Trennen von grob- und feinteiligem Material, das auf einem künstlichen Sportboden (8) aufgeschichtet ist, gekennzeichnet durch die Schritte:
 - Richten von Druckluft direkt und unter einem Anstellwinkel auf den Sportboden, um fein- und grobteiliges Material davon abzulösen;
 - Mitführen des fein- und grobteiligen Materials in einem Luftstrom;
 - Trennen des fein- und grobteiligen Materials in dem Luftstrom und
 - Zurückführen des grobteiligen Materials auf den Boden.
 15. Verfahren nach Anspruch 14, wobei der Richtschritt das Richten der Druckluft durch eine Vielzahl von in einer Reihe ausgerichteten feinen Löchern (13) einschließt.
 16. Verfahren nach Anspruch 14 oder 15, wobei der Richtschritt das Ausrichten der Druckluft bezüglich des Bodens unter einem Winkel von etwa 60° einschließt.
 17. Verfahren nach einem der voranstehenden Ansprüche, wobei der Trennschritt das Führen des abgelösten fein- und grobteiligen Materials durch ein Blasrohr einschließt, in dem der Schritt des Trennen durchgeführt wird.
 18. Verfahren nach einem der voranstehenden Ansprüche und das den weiteren Schritt des Sammelns des abgetrennten feinteiligen Materials umfaßt.
 19. Vorrichtung zum Weichmachen eines künstlichen Sportbodens, auf dem ein verdichtetes Teilchenmaterial aufgeschichtet ist, wobei die Vorrichtung ein Blasrohr (64) zum Aufnehmen von von dem Sportboden entferntem Teilchenmaterial aufweist, wobei das Blasrohr in einem unteren Bereich einen Auslaß umfaßt, mittels dessen das Teilchenmaterial auf den Sportboden zurückgeführt wird, dadurch gekennzeichnet, daß die Vorrichtung weiterhin aufweist:
 - einen angrenzend an das Blasrohr (64) angeordneten Stoßdiffusor (10) mit einem Drucklufteinlaß (61, 62) und mindestens einem Luftauslaß (63), durch den Luft unter einem Anstellwinkel direkt auf den Sportboden (8) ausstoßbar ist, um so das darauf aufgeschichtete Teilchenmaterial abzulösen und es in das Blasrohr (64) zu lenken, welches sich oberhalb des Stoßdiffusors (60) erstreckt.
 20. Verfahren zum Ablösen und Mitnehmen von Teilchenmaterial, das auf einem künstlichen Sportboden (8) aufgeschichtet ist, gekennzeichnet durch die Schritte:
 - Richten von Druckluft direkt und unter einem Anstellwinkel auf den Sportboden, um Teilchenmaterial davon abzulösen;
 - Mitführen des Teilchenmaterials in einem Luftstrom; und
 - Zurückführen des Teilchenmaterials mit dem Luftstrom auf den Boden.

Revendications

1. Dispositif (1) pour déloger, entraîner et séparer une matière particulaire grossière et fine, disposée en couche sur une surface de jeu (8) synthétique, le dispositif comprenant un collecteur (11) pour loger ladite matière particulaire grossière et fine déplacée depuis la surface de jeu, ledit collecteur comprenant un orifice (12) dans sa zone supérieure, par lequel la matière particulaire légère, fine, s'échappe, et une sortie dans une zone inférieure, au moyen de laquelle la matière particulaire grossière, lourde revient à la surface de jeu, caractérisé en ce que le dispositif comprend en outre :

un collecteur d'air d'aspiration (10) adjacent audit collecteur, ayant une entrée d'air comprimé (9) et au moins une sortie d'air (13) par laquelle l'air peut être expulsé selon un angle incliné, directement sur la surface de jeu (8), de manière à déloger la matière particulaire grossière et fine disposée en couche sur elle et pour l'orienter dans le collecteur (11) qui s'étend au-dessus du collecteur d'air d'aspiration (10).

2. Dispositif selon la revendication 1, dans lequel le collecteur d'air d'aspiration (10) est d'une configuration sensiblement tubulaire et s'étend depuis un côté du dispositif (1) vers l'autre, selon une disposition sensiblement horizontale, perpendiculairement à la direction dans laquelle le dispositif est adapté pour être passé sur la surface de jeu. 5
3. Dispositif selon la revendication 2, dans lequel une entrée d'air comprimé (9) est agencée à chaque extrémité du collecteur d'air d'aspiration (10) et la sortie comprend une pluralité de trous de cheville (13) alignés, formés le long d'un côté du collecteur d'air d'aspiration. 10
4. Dispositif selon la revendication 3, dans lequel les trous de cheville (13) ménagés dans le collecteur d'air d'aspiration sont alignés en formant un angle d'à peu près 60° par rapport à la surface de jeu. 15
5. Dispositif selon l'une quelconque des revendications précédentes, dans lequel le collecteur (11) est un conduit curviligne creux ayant une entrée longitudinale (15) adjacente à la sortie du collecteur d'air d'aspiration (10). 20
6. Dispositif selon la revendication 5, dans lequel le collecteur (11) comprend une partie adjacente à l'entrée longitudinale (15), qui s'étend vers le haut dans une direction sensiblement verticale et s'incurve ensuite selon un rayon d'incurvation constant, via une partie horizontale, vers une partie orientée vers le bas qui définit une sortie de matière particulaire grossière. 25
7. Dispositif selon la revendication 5, dans lequel le collecteur comprend une paroi adjacente à l'entrée longitudinale qui s'étend vers le haut de cette dernière, selon un rayon d'incurvation constant, via une zone moins incurvée vers une partie incurvée vers le bas qui définit la paroi extérieure, au niveau d'une sortie de matière particulaire grossière. 30
8. Dispositif selon la revendication 6 ou 7, dans lequel la sortie de matière particulaire grossière est suffisamment plus grande que l'entrée de collecteur (15) pour permettre une chute de la vitesse de l'air lorsqu'il passe de l'entrée de collecteur à la sortie, 35

pour répandre de ce fait la matière particulaire grossière sur la surface de jeu, en une couche uniforme.

9. Dispositif selon l'une quelconque des revendications précédentes, comprenant au moins une plaque déflectrice (17, 18) agencée pour envelopper partiellement le collecteur d'air d'aspiration (10), en vue d'empêcher la matière particulaire grossière d'être véhiculée dans l'orifice de collecteur (12) et de diriger la matière particulaire grossière vers la sortie de collecteur. 40
10. Dispositif selon l'une quelconque des revendications précédentes, monté sur un cadre à roues. 45
11. Dispositif selon la revendication 10, comprenant une chambre (43) pour collecter la matière particulaire fine séparée, ladite chambre comprenant un cyclone (40) connecté, par une entrée dans sa paroi latérale, à l'orifice du collecteur, au moyen d'un conduit (41). 50
12. Dispositif selon la revendication 11, comprenant un agencement de filtrage (44) connecté à une sortie, au niveau du sommet du cyclone qui permet à l'air d'être évacué vers l'atmosphère, tout en maintenant la matière particulaire fine. 55
13. Dispositif selon l'une quelconque des revendications précédentes, comprenant une source d'air comprimé pour fournir l'air comprimé au collecteur d'air d'aspiration.
14. Procédé pour déloger, entraîner et séparer une matière particulaire grossière et fine disposée en couche sur une surface de jeu (8) synthétique, caractérisé par les étapes de :
orientation d'air comprimé directement et selon un angle d'inclinaison sur la surface de jeu, pour en déloger la matière particulaire fine et grossière ;
entraînement de la matière particulaire fine et grossière dans un courant d'air ;
séparation de la matière particulaire fine et grossière dans ledit courant d'air ; et
renvoi de la matière particulaire grossière vers la surface.
15. Procédé selon la revendication 14, dans lequel l'étape d'orientation implique l'orientation de l'air comprimé via une pluralité de trous de cheville (13) alignés.
16. Procédé selon la revendication 13 ou 14, dans lequel l'étape d'orientation implique l'orientation de l'air comprimé selon un angle d'à peu près 60° par rapport à la surface.

17. Procédé selon l'une quelconque des revendications précédentes, dans lequel l'étape de séparation implique le passage de la matière particulaire fine et grossière délogée dans un collecteur dans lequel est effectuée l'étape de séparation. 5
18. Procédé selon l'une quelconque des revendications précédentes, comprenant l'étape supplémentaire de collecte de la matière particulaire fine séparée. 10
19. Dispositif pour ramollir une surface de jeu synthétique ayant, disposée en couche sur elle, une matière particulaire compactée, le dispositif comprenant un collecteur (64) pour recevoir une matière particulaire déplacée depuis la surface de jeu, ledit collecteur comprenant une sortie dans une zone inférieure, au moyen de laquelle la matière particulaire est renvoyée à la surface de jeu, 15
- caractérisé en ce que le dispositif comprend en outre : 20
- un collecteur d'air d'aspiration (60), adjacent audit collecteur (634), ayant une entrée d'air comprimé (61, 62) et au moins une sortie d'air (63) par laquelle l'air peut être expulsé selon un angle incliné, directement sur la surface de jeu, de manière à déloger la matière particulaire y étant disposée en couche et à l'orienter dans le collecteur (64) qui s'étend au-dessus du collecteur d'air d'aspiration (60). 25
20. Procédé pour déloger et entraîner une matière particulaire disposée en couche sur une surface de jeu (8) synthétique, caractérisé par les étapes de : 30
- orientation d'air comprimé directement sur et selon un angle incliné avec la surface de jeu, pour en déloger la matière particulaire ; 35
- entraînement de la matière particulaire dans un courant d'air ; et
- renvoi de la matière particulaire à la surface conjointement avec ledit courant d'air. 40
