(54) Title: DEVICE FOR SURGERY WHEN PREPARING FOR DENTAL IMPLANTS

Fig. 2

(57) Abstract: A device for preparing for dental implants comprises an elongate structure that has a first end (1) with a tip (4), wherein a set of cutting fins (5) are arranged on the structure adjacent the first end (1), and a second end (2) with a connecting part (6) adapted to be coupled to a rotating device for rotating the device such that the first end (1) of the elongate structure is arranged coaxially inside a cylinder element (3). The set of cutting fins (5) comprises three fins evenly arranged around the elongate structure at an angle of 120° between them, wherein the outer ends (10) of the cutting fins (5) are linked to the inner surface of the cylinder element.

DEVICE FOR SURGERY WHEN PREPARING FOR DENTAL IMPLANTS

TECHNICAL FIELD

5 The present invention relates to a device for preparing for dental implants comprising an elongate structure that has a first end with a tip. A set of cutting fins are arranged on the structure adjacent the first end and a second end with a connecting part is adapted to be coupled to a rotating device for rotating the device such that the first end of the elongate structure is arranged coaxially inside a cylinder element.

10

BACKGROUND

There are devices available for removing soft (mucous) and hard (bone) tissues for use in a surgical, medical or other environment where soft tissue or crushed bone particles need to be removed for autografting.

15

Ground bone particles can be used in a variety of medical and surgical procedures. For example, finely ground bone particles can be used for spinal fusions, to repair defects caused by trauma, microsurgery, oral and maxillofacial surgery, dental surgery, transplant surgery or tissue banking.

20

Currently, a surgeon can remove a portion of bone from a patient, grind the portion into fairly homogeneous particles using a hand-held rasp, and use the bone particles to fill and repair another area of bone, such as in the patient's spine, skull, maxilla or mandible.

25

The step of grinding the bone portion using a hand rasp is a relatively long and strenuous operation, with mixed results as it depends on the type of bone, the scraper and the skill of the operator.

30

As well as the scraper there are other instruments used in surgery, such as the use of a conventional trephine, here the surgeon obtains a cylinder of compact bone, which must be crushed by using a grinder or grinder, to obtain smaller pieces of bone and place it in the area to be repaired, therefore the instruments used must be sterile and maintain a sterile environment during the surgical procedure.

35

Normally, a surgical instrument is sterilised before and/or after the surgical procedure to disinfect it and remove any toxic residues and other contaminants. In the current state of the art, tools for preparing for dental implants are well known, which generally
5 comprise a tubular body that has a sharp edge for cutting the gum through the immediate loading process.

Specifically, the immediate loading process is a process in which the dental prosthesis is installed immediately after the surgical procedure.
10

The problem with this type of tool is that they do not cleanly, precisely and rigidly cut the patient's gums, causing the cut to be sutured incorrectly and there are bleeding problems during the procedure and after surgery.

15 Instruments such as a hand-operated scaler or electric grinder are usually disassembled, sterilized by autoclaving or other sterilization procedure and then reassembled. This process also introduces an element of time and expense that must be factored into the surgical procedure.

20 In addition, scrapers and trephines in general have certain deficiencies. Most of the time, they are wasteful, as it is difficult to remove all bone particles from them. In addition, growth factors inherent to bone tissue can be lost, and there is no way to mix various additives to the bone particles, such as bone-inducing materials that promote bone growth, during the removal and repair process.

25 As for the soft tissue extraction device, it is a minimally invasive instrumentation that allows the removal of any epithelial, mucosal or submucosal tissue and even from deeper planes. Its structure and design is the same as that of the hard tissue extraction device, changing only the external tubular structure.

30 ES1136608U describes a tool for preparing for dental implants, which integrates two independent pieces that are coaxially coupled to each other in a detachable way by threads, such that, the tool includes two cutting fins.

Although this device solves the problem related to cutting precision and also the lack of rigidity, it maintains the problem related to precision, cortical regularization, self-centering and knowing the spatial relationship of neighboring pieces.

- 5 Hence, the object of the present disclosure is to provide a tool that at least alleviates some of the issues of prior art tools.

SUMMARY

- 10 According to a first aspect of the present disclosure a device for preparing for dental implants comprises an elongate structure that has a first end with a tip, wherein a set of cutting fins are arranged on the structure adjacent the first end. Further, a second end with a connecting part is adapted to be coupled to a rotating device for rotating the device such that the first end of the elongate structure is arranged coaxially inside
15 a cylinder element. The set of cutting fins comprises three fins evenly arranged around the elongate structure at an angle of 120° between them, wherein the outer ends of the cutting fins are linked to the inner surface of the cylinder element.

- The fins grind the cut material into smaller particles, for use in a sterile surgical
20 environment, and a coupling such as a rotating shaft for connection to an electro-mechanical or pneumatic system.

- According to a preferred aspect of the present disclosure the device comprises a second set with three cutting fins arranged around the elongate structure at an angle
25 of 120° between them and arranged between the first set of cutting fins and the second end at a distance from the first set of cutting fins.

- According to another aspect of the present disclosure, the hardness of the fins of the second set compared to the first set differ for better handling of varying hardness of
30 bones without having to dismantle and switch the fins.

- The fins of the two sets are according to a further aspect of the present disclosure arranged around the elongate structure such that the fins of the first set is arranged at a rotational angle of 60° relative the fins of the second set.

According to yet a further aspect of the present disclosure the cutting fins have cutting edges towards the first end of the elongate structure.

5 According to another aspect of the present invention the cutting fins comprise truncated pyramidal bodies with rectangular bases arranged towards the second end of the device and further comprise slanted lateral faces and top surfaces of the cutting edges arranged towards the first end of the device.

10 The lateral faces of the truncated pyramidal bodies are according to one aspect of the present disclosure curved concave planes.

According to yet another aspect of the present disclosure the first end of the elongate structure has an annular extension, the cylinder element having an internal space and a seat extending inwardly from the inner surface of the cylinder element and
15 corresponding to the annular extension, wherein the cylinder element and the annular extension are arranged such that coaxial movement of the cylinder element relative the elongate structure is limited upon contact between the annular extension and the seat .

20 According to a further aspect of the present disclosure the cylinder element has distance markings for facilitating for the surgeon to help seeing how deep the device has been inserted.

25 According to one aspect of the present invention the first end of the elongate structure and cylinder element have respective threaded surfaces, such that the elongate structure and the cylinder element are arranged to be screwed together such that the first end of the elongate structure is disposed coaxially inside the bushing.

30 According to an alternative aspect of the present disclosure the first end of the elongate structure and the cylinder element have respective adherent surfaces, such that the first end of the elongate structure is joined coaxially inside the cylinder element.

35 It should be emphasized that the term “comprises/comprising” when used in this specification is taken to specify the presence of stated features, integers, steps or

components but does not preclude the presence or addition of one or more other features, integers, steps, components or groups thereof.

Further features of, and advantages with, the present invention will become apparent
5 when studying the appended claims and the following description. The skilled person realize that different features of the present invention may be combined to create embodiments other than those described in the following, without departing from the scope of the present invention.

10 BRIEF DESCRIPTION OF THE DRAWINGS

The above, as well as additional objects, features and advantages of the present invention, will be better understood through the following illustrative and non-limiting detailed description of exemplary embodiments of the present invention, wherein:

15

Figure 1 shows an exploded view of an embodiment of the device made according to the object of the present invention.

20

Figure 2 shows a view of the assembled device assembly according to the embodiment illustrated in figure 1.

Figure 3 shows a sectional cut (B-B) of figure 2, corresponding to the end of the cylinder element of the device.

25

Figure 4 shows a detailed view of the cutting fins of the device.

Figure 5 shows a view of a further embodiment of the device.

30

Figure 6 shows a view of the device made in accordance with the object of the further embodiment of the invention, where distance marking is included on the device.

Figure 7 is a axial view showing the cutting fins of the first and second set.

35

Figure 8 shows the first steps followed during the use of the device of the present invention.

Figure 9 shows the last stages followed during the use of the device of the present invention.

5 Figure 10 is a side view of a further embodiment of the device.

Figure 11 shows the embodiment in figure 10 in assembled state.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS OF THE INVENTION

10

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which exemplary embodiments of the invention are shown. The invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these
15 embodiments are provided for thoroughness and completeness. Like reference character refer to like elements throughout the description.

With reference to figure 1 the elongate structure has a first end 1 made up of a tip 4 associated with cutting fins 5, and a second end 2 associated with a connecting part
20 6 for coupling to a rotating device that drives the device. As detailed above, the cutting fins 5 are arranged at an angle of 120° between them, where the outer ends 10 of the cutting fins 5 are linked to the internal surface of the cylinder element 3.

Thus, in figure 2 it can be seen how, in a preferred embodiment, the first end 1 of the
25 tubular structure and the bushing 3 have respective threaded surfaces 12, so that the first end 1 of the structure tubular is disposed coaxially inside the bushing 3 by threading.

As also can be seen in figures 1 and 2 the device comprises a second set 19 with
30 three cutting fins arranged around the elongate structure at an angle of 120° between them and arranged between the first set of cutting fins 5 and the second end 2 at a distance from the first set of cutting fins 5.

The hardness of the fins of the second set 19 compared to the first set 5 may differ for better handling of varying hardness of bones without having to dismantle and switch the fins.

- 5 The fins of the two sets 5, 19 are arranged around the elongate structure such that the fins of the first set 5 is arranged at a rotational angle of 60° relative the fins of the second set 19, see figure 7.

On the other hand, in figure 5 a second embodiment is shown where the first end 1 of
10 the elongate structure and the cylinder element 3 have respective adherent surfaces so that the first end 1 of the elongate structure is joined coaxially inside the cylinder element 3. The cylinder element 3 and the elongate structure remain associated with each other, generating a sealed inner surface that prevents the accumulation of dirt.

15 Additionally, figure 4 shows a perspective detail of the first end 1 of the elongate structure, where the cutting fins 5 of the first set, arranged on the first end 1 of the elongate structure, incorporate cutting edges 7 that provide robustness to the assembly and allow cutting and extraction to be carried out in a single step.

20 In this sense, in figure 3, it is observed that the cutting edges 7 of the cutting fins 5 comprise truncated-pyramidal bodies with rectangular bases. The two slanted lateral faces 7a are made up of two concave planes, while the flat edges of the said truncated pyramidal bodies constitute the top surfaces 7b of the cutting edges 7 during the rotation of the device. Advantageously, this configuration favors the extraction of the
25 parts of the gum that are being cut during the surgical procedure.

It should be noted that, as can be seen in figures 1, 2 and 5, in both embodiments, the configuration of the inner surface of the cylinder element 3 has a recess 9 that generates an internal seat 9a. On the other hand, the first end 1 of the elongate
30 structure has an annular extension 8 so that when combined with the internal seat 9a butting against it, the cylinder element 3 is immobilized and thus fixed in a more stable way.

Figure 6 shows how the cylinder element 3 has an engraving as distance markings 11
35 that, when carrying out the surgical operation, allows the user to carry out the process

of cutting and extracting the gum from a guided and precise way. This engraving may optionally be included in any of the embodiments of the invention.

Turning to figures 10 and 11, a further embodiment of the device is shown where the
5 cylinder element 3 is a trephine, i.e., with a toothed distal edge 20. The toothed edge is sometimes advantageous as compared to a scalpel edge 21, see figures 1, 2, 3, 5, and 6, and vice versa.

Finally, as shown in figures 8 and 9, in the procedure followed during the use of the
10 scalpel for making dental implants of the invention, it is necessary to highlight the following stages during the guided surgery with a splint.

- Stage A: Placement of a splint 13 on the gum 14 where it is desired to place the implant and insertion of the device, so that the tip 4 of the first end 1 of the device
15 of the invention rests centered in the space delimited by the splint 13.

- Stage B: Circular cutting of the gum 14 to access the bone 15.

- Stage C: Extraction of the cut fragments of the gingiva and cortical
20 regularization of the bone 15.

- Stages D and E: Milling. For this, the tip 4 of the device is replaced by a drill 16 that acts as a pilot during the placement of the implant 17. Advantageously, the distance markings 11 included in the cylinder element 3 of the device of the invention
25 allows the user to be guided during surgical surgery.

- Stage F: The device allows for the placement of the implant 17.

- Stage G: Final placement of the tooth 18 on the implant 17.
30

As used herein, the singular forms "a", "an" and "the" are intended to include the plural forms as well, unless expressly stated otherwise. It will be further understood that the terms "includes," "comprises," "including" and/or "comprising," when used in this specification, specify the presence of stated features, integers, steps, operations,
35 elements, and/or components, but do not preclude the presence or addition of one or

more other features, integers, steps, operations, elements, components, and/or groups thereof. It will be understood that when an element is referred to as being "connected" or "coupled" to another element, it can be directly connected or coupled to the other element or intervening elements may be present. Furthermore,
5 "connected" or "coupled" as used herein may include wirelessly connected or coupled. As used herein, the term "and/or" includes any and all combinations of one or more of the associated listed items.

10 While several embodiments of the present invention have been described and illustrated herein, those of ordinary skill in the art will readily envision a variety of other means and/or structures for performing the functions and/or obtaining the results and/or one or more of the advantages described herein, and each of such variations and/or modifications is deemed to be within the scope of the present invention. More
15 generally, those skilled in the art will readily appreciate that all parameters, dimensions, materials, and configurations described herein are meant to be exemplary and that the actual parameters, dimensions, materials, and/or configurations will depend upon the specific application or applications for which the teachings of the present invention is/are used.

CLAIMS

1. A device for preparing for dental implants, comprising an elongate structure that has a first end (1) with a tip (4), wherein a set of cutting fins (5) are arranged
5 on the structure adjacent the first end (1), and a second end (2) with a connecting part (6) adapted to be coupled to a rotating device for rotating the device such that the first end (1) of the elongate structure is arranged coaxially inside a cylinder element (3),
c h a r a c t e r i z e d i n
10 that the set of cutting fins (5) comprises three fins evenly arranged around the elongate structure at an angle of 120° between them, wherein the outer ends (10) of the cutting fins (5) are linked to the inner surface of the cylinder element.
2. The device according to claim 1, comprising a second set with three cutting
15 fins arranged around the elongate structure at an angle of 120° between them and arranged between the first set of cutting fins (5) and the second end (2) at a distance from the first set of cutting fins (5).
3. The device according to claim 2, wherein the fins of the two sets are arranged
20 around the elongate structure such that the fins of the first set is arranged at a rotational angle of 60° relative the fins of the second set.
4. The device according to any of the preceding claims, wherein the cutting fins
25 (5) have cutting edges (7) towards the first end of the elongate structure.
5. The device according to claim 4, wherein the cutting fins (5) comprise truncated
pyramidal bodies with rectangular bases arranged towards the second end (2)
of the device, further comprising slanted lateral faces (7a) and top surfaces
(7b) of the cutting edges (7) arranged towards the first end of the device.
30
6. The device according to claim 5, wherein lateral faces (7a) of the truncated
pyramidal bodies are curved concave planes.
7. The device according to any of the preceding claims, wherein the first end (1)
35 of the elongate structure has an annular extension (8), the cylinder element (3)

- 5 having an internal space (9) and a seat (9a) extending inwardly from the inner surface of the cylinder element (3) and corresponding to the annular extension (8), wherein the cylinder element (3) and the annular extension (8) are arranged such that coaxial movement of the cylinder element (3) relative the elongate structure is limited upon contact between the annular extension (8) and the seat (9a) .
8. The device according to any of the preceding claims, wherein the cylinder element (3) has distance markings (11).
- 10 9. The device according to any of the preceding claims, wherein the first end (1) of the elongate structure and cylinder element (3) have respective threaded surfaces (12), such that the elongate structure and the cylinder element (3) are arranged to be screwed together such that the first end (1) of the elongate structure is disposed coaxially inside the bushing (3).
- 15 10. Scalpel for making dental implants, according to any of the claims 1 to 8, wherein the first end (1) of the elongate structure and the cylinder element (3) have respective adherent surfaces, such that the first end (1) of the elongate structure is joined coaxially inside the cylinder element (3).
- 20 11. Trephine for making dental implants, according to any of the claims 1 to 8, wherein the first end (1) of the elongate structure and the cylinder element (3) have respective adherent surfaces, such that the first end (1) of the elongate structure is joined coaxially inside the cylinder element (3).
