METHOD AND COMPOSITION FOR DETERMINING ANTIMICROBIAL  
SUSCEPTIBILITY OF THE MAJORITY OF CLINICALLY SIGNIFICANT GRAM  
POSITIVE ORGANISMS

Field of the Invention

5           This invention relates to a method to determine  
susceptibility to antimicrobial agents of a wide variety of  
clinically significant Gram positive organisms. This invention  
also relates to a mixture of fluorogenic substrates used to detect  
the growth of Gram positive bacteria.

10           Background of the Invention

Microorganisms isolated from patients and other sources are  
routinely tested for their susceptibility to antimicrobial agents  
and for their metabolic growth requirements. In particular, the  
minimum inhibitory concentrations (MIC's) of antimicrobial agents  
15           or the categorical interpretations (susceptible, moderately  
susceptible, or resistant) of microorganisms isolated from  
clinical sources are routinely determined.

Numerous methods and apparatus have been developed to  
conduct susceptibility tests. In particular, multi-  
20           compartmentalized devices, such as microdilution panels, with each  
compartment containing a specific quantity of an antimicrobial  
agent or a growth promoting material, such as a vitamin, are often  
used to determine growth and susceptibilities. These compartments  
generally contain, in addition to the agent investigated, growth  
25           supporting medium. These devices may be freshly prepared, frozen  
or dried for convenient storage.

To conduct susceptibility tests the above described devices  
are inoculated with a standardized microbiological inoculum and  
incubated until visible growth appears. This typically takes 15-  
30           24 hours. Generally, microbial growth in either a liquid medium  
or on the surface of a solid support medium is determined by  
direct visual recognition or by turbidimetric measurements. The  
endpoint of susceptibility tests is defined as the lowest  
concentration of an antimicrobial agent in which growth, when  
35           compared to that of the growth compartment, appears to be  
inhibited.

Commonly used susceptibility tests require 15-24 hours of incubation prior to the availability of results. Earlier receipt by the physician of accurate antimicrobial agent susceptibility information would result in better patient treatment. A number of methods have been published to obtain earlier susceptibility determinations. They may be divided into measurement of bacterial mass described in Patent Nos. 4,236,211 (Pfizer), 3,832,532 (Pfizer), G.B. Patent No. 1,554,134 (Pfizer), and indirect estimation of bacterial mass by measurement of enzymatic activity described in Patent No. 4,242,447 (Bio Research), fluorogenic measurement of phosphate, Patent No. 3,509,026 (Litton Systems Inc.), fluorogenic measurement of phosphatase, FR 2,504,679, use of methylumbelliferyl derivatives, EP 0,091,837B and in articles describing the use of amido-coumarin derivatives for antibiotic susceptibility testing by M.R. Mateo, et al., Abstract Annual Meeting, American Society for Microbiology, 1980, C201, p308 and the measurement of metabolic activity by reduction of tetrazolium in microdilution panels by T. Urban and C. Jarstrand, J. Antimicro. Chemo (1981) 8, 363-369. All the following are about the use of a mixture of fluorogenic substrates: Nolte et al., J. Clin. Microbio. (1988) 26, 1079-1084, Staneck et al., J. Clin. Microbiol. (1985), 187-191, Doern et al., J. Clin. Micro. (1987), 1481-1485, and Staneck et al., J. Clin. Micro. (1988) v.26 1-7.

One particular method is the Sensititre<sup>TM</sup> system which has an instrument capable of automatically reading antimicrobial susceptibility microdilution trays. In this procedure, microbial growth is determined by the measurement of fluorescence produced by bacterial enzymatic action on fluorogenic substrates. The fluorescence signals are interpreted by the instrument and converted to MIC's. Staneck, (1985) Supra at 187. The Sensititre<sup>TM</sup> method involves the use of a fluorogenic substrate cocktail to detect the minimal inhibitory concentration for Gram positive and Gram negative bacteria based on a single measurement within five hours of the addition of the hydrolysable

fluorogenic substrates to the inoculum. It is disclosed that the fluorogenic substrates for this group of bacteria are selected from 7-(N)-(aminoacyl)-7-amido-4-methylcoumarin, 4 methyl-umbelliferyl nonanoate, 4-methylumbelliferyl phosphate. EP #0,091,837B.

5  
10  
15  
20  
25  
Single measurement methods to predict or determine minimal inhibitory concentration using fluorogenic substrates, however, have been found to be unreliable. In order to determine accurate minimal inhibitory concentrations sufficient growth and utilization of the substrate must occur. A single measurement precludes the accurate determination of a minimal inhibitory concentration under optimum conditions because different bacterial species may obtain sufficient growth to determine minimal inhibitory concentrations at different times. A single early measurement may result in an inaccurate prediction of a minimal inhibitory concentration because of insufficient expression of resistance. A single late measurement may result in an inaccurate estimation of enzymatic activity in the antimicrobial agent containing compartment in relation to that of the growth compartment. After a certain fluorescence level is reached, the photometric detection system is unable to accurately determine fluorescence. Consequently, a need exists to develop a system to accurately predict minimal inhibitory concentrations for a wide range of Gram positive organisms using fluorogenic substrates in one standardized test system.

#### Summary of the Invention

30  
35  
The present invention involves a method for determining antimicrobial susceptibility of a wide variety of Gram positive organisms comprising: a) suspending and homogeneously mixing a sufficient number of morphologically similar colonies of the Gram positive organism in an aqueous suspending medium to prepare an inoculum having a turbidity equivalent to at least 0.5 McFarland Barium Sulfate, turbidity standard; b) diluting said inoculum in a sufficient amount of a growth supporting medium to achieve a nominal concentration of about  $2 \times 10^6$  colony forming units/ml;

c) combining a portion of said inoculum with a sufficient amount of fluorogenic substrates consisting of: leucine-7-amido-4-methylcoumarin, phenylalanine-7-amido-4-methylcoumarin and 4-methylumbelliferyl phosphate and a predetermined amount of an antimicrobial agent to form a mixture; d) repeatedly monitoring fluorescence intensity of said mixture between about 3 1/2 to 15 hours after step 1(c) to detect a given increase in fluorescence intensity and e) comparing said detected fluorescence intensity with changes in fluorescence intensity of a control or controls to determine susceptibility to antimicrobial agents of said Gram positive organisms. A kit to conduct the above described method comprised of control, growth control, and antimicrobial agents in individualized compartments: said control compartments containing buffer, said growth control compartments containing buffer and fluorogenic concentrate, and said antimicrobial agent compartment containing buffer, antimicrobial agent and fluorogenic concentrate. All kit biochemical components are in a stable format, such as in the dehydrated state.

The invention differs from the procedure previously described for Gram positive bacteria used by Sensititre™ EP #0,091837 in three important aspects. Firstly, the mixture of fluorogenic enzyme substrates; secondly, in the scope of organisms covered; and thirdly, in the repeated measurement of fluorescence.

In the Sensititre™ procedure the substrates mixture consists of alanyl-7-amido-4-methylcoumarin, 4-methylumbelliferyl phosphate and 4-methylumbelliferyl nonanoate. The last compound is difficult to redissolve evenly after dehydration. Moreover, a special procedure of drying the substrate mixture on a solid carrier in combination with an emulsifying agent was the preferred method in the EP #0,091837 description. Removal of this compound from the mixture allows easy preparation and aliquoting of the fluorogenic substrate mixture. In the current invention phenylalanine-7-amido-4-methylcoumarin and leucine-7-amido-4-methylcoumarin provide a superior mixture to that described before because it removes the need for an emulsifying agent during drying

and the need of drying the fluorogenic enzyme substrates on a solid carrier. The current fluorogenic substrate mixture also allows for testing of a larger range of Gram positive species than previously described. Additionally, the use of the autoSCAN<sup>R</sup>-W/A allows monitoring of growth for between 3 1/2 and 15 hours, determination of minimum inhibitory concentration occurring only when sufficient growth has been achieved. This ensures that the minimum inhibitory concentration determinations of each isolate is determined at the optimal time.

10 Detailed Description

The invention combines three fluorogenic compounds to facilitate the detection of growth of the majority of clinically significant Gram positive organisms, staphylococci, streptococci, enterococci, and listeriae from between about 3 1/2-15 hours. The combination of the three compounds are added to the growth control and to every concentration of the antimicrobial agents compartments. Growth of the organism is detected by an increase in fluorescence units.

As the organism grows, enzymes are produced which hydrolyze the fluorogenic compound(s), thus releasing the fluorophore, which, when excited by light in the 340-370nm range, fluoresces in the 440-470nm range. If the organism does not grow, the fluorophore part is not released from the compound, and there is no increase in fluorescence at the selected wavelength. After the organism has grown for between 3 1/2-15 hour, the amount of fluorescence in the individual concentrations of the antimicrobial agents can be compared to the amount of fluorescence in the growth control, and the minimal inhibitory concentrations of each antimicrobial agent can be determined.

The advantage of utilizing a combination of fluorogenic compounds to detect growth, is the rapidity with which growth and consequently minimal inhibitory concentrations can be determined. Conventional minimal inhibitory concentration determinations, which rely on turbidity, require 15-24 hours of incubation prior to reading. Using a combination of certain compounds allows one

to determine minimum inhibitory concentrations for the majority of Gram positive organisms, however, within 3 1/2-15 hours.

Several combinations of fluorogenic compounds were tested and this combination detected growth of most species of Gram positive organisms. The compounds are leucine-7-amido-4-methylcoumarin, phenylalanine-7-amido-4-methylcoumarin, and 4-methylumbelliferyl phosphate. This combination detected the majority of clinically relevant species of staphylococci, streptococci, enterococci, and listeriae. See TABLE 1.

In particular, in this assay as the organism grows it metabolizes one, two, or all three components of the fluorogenic concentrate. Metabolic activity results in the release of fluorophores, amino-4-methylcoumarin and/or 4-methylumbelliferone which, when excited by light in the 340-370 nm range, emit light (fluoresce) in the 440-470 nm range. As the organism multiplies, the amount of fluorescence increases. The amount of fluorescence in each concentration of the antimicrobial agents is compared to the amount of fluorescence in the growth control. Using a mathematical model based on discriminate functional analysis, the minimum inhibitory concentration of each antimicrobial agent, for the organism tested, can be determined. Utilization of a

discriminant function analysis model in microbiological pattern recognition is described in S. Bascomb, Computers in Taxonomy and Systematics, p.65-102 In T.N. Bryant and J.W.T. Wimpenny (Ed.), Computers in Microbiology, a Practical Approach (IRL Press, Oxford). In an alternative embodiment the minimal inhibitory concentration for each antimicrobial agent for the organism tested can be determined by a break point or threshold method or by linear regression analysis. J. McKie, et al., Antimicrobial Agents and Chemotherapy (1980) v.17, 813-823.

20  
25  
Generally, the invention involves making a stock solution containing the three fluorogenic compounds: leucine-7-amido-4-methylcoumarin (0.1M), phenylalanine-7-amido-4-methylcoumarin (0.05M) and 4-methylumbelliferyl phosphate (0.25M); dissolving the compounds in dimethylformamide; b) making the diluent which is HEPES buffer, 0.01M, pH 7.0 or a similar buffer. The antimicrobial agents are diluted in 0.01M buffer; and the fluorogenic concentrate (2ml/L) is added to the growth control, which contains only buffer, and to each concentration of the antimicrobial agents. Additionally, a control which contains only buffer is used in this assay. The final concentration of the fluorogenic components per compartment are 0.2mM leucine-7-amido-4-methylcoumarin, 0.1mM phenylalanine-7-amido-4-methylcoumarin, and 0.5mM methylumbelliferyl phosphate. These concentrations were selected to assure optimum enzyme activity throughout the growth period. One hundred fifteen microliters of each of said solutions are dispensed into individual compartments of a microdilution panel. The panels are dehydrated and packaged in foil wrapping with a packet of desiccant. This package is stored at 2-8°C.

30  
35  
The antimicrobial agents include: Amoxicillin/K, Clavulanate (Aug), Ampicillin (am), Ampicillin/Sulbactam (A/S), Cefamandole (Cfm), Cefazolin (Cfz), Cefotaxime (Cft), Ceftriaxone (Cax), Cefuroxime (Crm), Cephalothin (Cf), Chloramphenicol (C), Ciprofloxacin (Cp), Clindamycin (Cd), Erythromycin (E), Gentamicin (Gm), Gentamicin Synergy Screen (GmS) Imipenem (Imp),

5 Nitrofurantoin (Fd), Norfloxacin (Nx), Oxacillin (Ox), Penicillin (P), Rifampin (Rif), Streptomycin Synergy Screen (Sts) (high concentration streptomycin in well. The screen determines that a combination of streptomycin and another antibiotic will be affective.), Tetracycline (Te), Trimethoprim (T), Trimethoprim Sulfamethoxazole (T/S) and Vancomycin (Va).

10 Generally, the test procedure involves making a suspension of a Gram positive organism, which is equivalent to a 0.5 McFarland barium sulfate turbidity standard in a saline pluronic broth. Three hundred microliters of the suspension is diluted into 25 milliliters of the inoculum broth. The suspension is mixed. The dried panels are rehydrated with 115 microliters of the inoculum broth per suspension. Rapid Pos<sup>R</sup> Inoculum Broth (Baxter MicroScan). The panels are incubated at 35° ± 1°C in a non-CO<sub>2</sub> incubator. The panels are read in a fluorometer at designated times. MicroScan has an autoScan<sup>R</sup> W/A (Baxter MicroScan) instrument which incubates and reads the panels automatically at designated times.

15 The following table shows the distribution of reagents and inoculum in the growth control and antimicrobial agent wells.

\*VMJ - Very Major Error - A very major error occurred when the isolate was categorized as susceptible by the test method and as resistant by the reference method.

\*\*MAJ - Major Error - A major error occurred when the isolate was categorized as resistant by the test method and as susceptible by the reference method.

\*\*\*MIN - Minor Error - A minor error occurred when the isolate was categorized as moderately susceptible by one method and as susceptible or resistant by the other method.

40

45

Examples of the invention are given below:

Example 1

5 A primary inoculum suspension of a bacterial isolate in saline-pluronic, equivalent to a 0.5 McFarland turbidity standard is prepared. The final inoculum suspension is prepared by diluting a 0.3ml aliquot of the primary suspension in 25ml of Rapid Pos Inoculum Broth (B1015-14, Baxter Diagnostics Inc., MicroScan Division, West Sacramento, CA). A 115ul of the final inoculum is added to the growth compartment which contains dried material of fluorogenic enzyme substrates equivalent to 0.023mM leucine-7-amido-4-methylcoumarin, 0.012mM phenylalanine-7-amido-4-methylcoumarin and 0.058mM methylumbelliferyl phosphate and 1.15mM HEPES buffer at pH 7.0. The final inoculum is also added to a number of compartments containing dried material identical to that in the growth well and different concentrations of an antimicrobial agent. An aliquot of the final inoculum is also added to a compartment, containing only dried HEPES buffer, acting as a control. The inoculated multicompartement device (panel) is inserted in the autoSCAN<sup>R</sup>-W/A. The fluorescence of each compartment is measured at predetermined times and a Growth Index is calculated by dividing the fluorescence of the growth compartment by that of the negative control compartment. See Table 4.

TABLE 4

$$\begin{aligned}
 & \text{Growth Factor} && \frac{Fl_{\text{growth well}}}{Fl_{\text{control well}}} \\
 & \frac{\% Fl_{\text{drug}}}{Fl_{\text{drug}}} &= & \frac{Fl_{\text{drug}} - Fl_{\text{control}}}{Fl_{\text{growth}} - Fl_{\text{control}}}
 \end{aligned}$$

30 If the value of the Growth Index is equal to or exceeds a specified value, the Minimum Inhibitory Concentration for every antimicrobial agent present in the multicompartement device is calculated. Otherwise the device is returned to its position and measured again at the next read time. The read times in this

example are 3.5, 4.5, 5.5, 7.0, 8.0, 11.0, and 15.0 hours. For calculation of minimum inhibitory concentration, the percent fluorescence of compartments containing the different concentrations of the antimicrobial agent is calculated by subtracting from each compartment the fluorescence of the control well and dividing it by the delta fluorescence of the growth compartment, obtained by subtracting the fluorescence of the negative control compartment from the fluorescence of the growth compartment. The minimum inhibitory concentration is calculated using a mathematical model specific for each concentration range of the antimicrobial agent. Using a mathematical model based on discriminate functional analysis, the minimum inhibitory concentration of each antimicrobial agent, for the organism tested, can be determined. Utilization of a discriminate function analysis model in microbiological pattern recognition is described in S. Bascomb, *Computers in Taxonomy and Systematics*, p.65-102 In T.N. Bryant and J.W.T. Wimpenny (Ed.), *Computers in Microbiology, a Practical Approach* (IRL Press, Oxford). In an alternative embodiment the minimum inhibitory concentration for each antimicrobial agent for the organism tested can be determined by a breakpoint or threshold method or linear regression analysis. J. McKie, et al., *Antimicrobial Agents and Chemotherapy* (1980) v.17, 813-823.

In Example 1, the growth of Enterococcus faecalis in wells containing specified amounts of antimicrobial agents is estimated by measurement of fluorescence. In Table 7, the percent fluorescence at different concentrations of antimicrobial agents is reported. For example, .12, .25, .5, 1, 2, 4 and 8 µg/mL of ampicillin (Am) were present in the microdilution wells.

The numbers 105, 105, 67, 7, 6, 5, 6 are percent fluorescence values as calculated in Table 4. These figures are used to determine susceptibility according to the methods discussed on pages 12 and 13.

In Table 8, the minimum inhibitory concentration for Example 1 are reported. For the antimicrobial agent, cephalothin, the organism was found to be susceptible at a concentration at 16  $\mu\text{g/mL}$ . For ampicillin/sulbactams susceptibility was observed at less than 8  $\mu\text{g/mL}$  while the organism was resistant to trimethoprim/sulfamethoxazole at greater than 8  $\mu\text{g/mL}$ . The organism was susceptible to norfloxacin, cefotaxime and chloramphenic at less than 4  $\mu\text{g/mL}$ , while susceptibility at 4  $\mu\text{g/mL}$  was observed of Imipenem and erythromycin. Additionally, the organism was found to be susceptible at less than 2  $\mu\text{g/mL}$  of vancomycin and amoxicillin/K.Clavulanate and at 2  $\mu\text{g/mL}$  of rifampin. The organism was resistant at greater than 2  $\mu\text{g/mL}$  of clindamycin. The organism was found to be susceptible at less than 1  $\mu\text{g/mL}$  of ciprofloxacin. The organism was found to be susceptible to 0.5  $\mu\text{g/mL}$  of ampicillin. The organism was found to be susceptible at 128  $\mu\text{g/mL}$  to tetracycline. The organism was found to be susceptible to less than 32  $\mu\text{g/mL}$  of nitrofurantoin.

The organism was found to be resistant at greater than 16 µg/mL for cefazolin, cefuroxime, and cefamandole. Additionally, it was determined that this organism was susceptible to a Streptomycin Synergy Screen.

5           Variants or equivalents: one alternative would be to use other combinations of fluorogenic compounds. The combination described above worked the best and detected the greatest number of Gram positive organisms. Other compounds tested were alanine-7-amido-4-methylcoumarin and methionine-7-amido-4 methylcoumarin.  
10       The individual concentrations of the compounds or the ratio of compounds in the mixture could be varied.

## WE CLAIM:

1. A method for determining susceptibility to antimicrobial agents of the majority of clinically significant gram positive organisms comprising:
  - 5 a. suspending and homogenously mixing a sufficient number of morphologically similar colonies of Gram positive organisms in an aqueous suspending medium to prepare an inoculum having a turbidity equivalent to at least 0.5 McFarland barium sulfate, turbidity standard;
  - 10 b. diluting said inoculum in a sufficient amount of growth supporting medium to achieve a nominal concentration of about  $2 \times 10^6$  colony forming units/ml;
  - 15 c. combining a portion of said inoculum with a sufficient amount of fluorogenic substrates consisting of: leucine-7-amido-4-methylcoumarin, phenylalanine-7-amido-4-methyl coumarin and 4-methylumbelliferyl phosphate and predetermined amount of an antimicrobial agent to form a mixture;
  - 20 d. monitoring fluorescence intensity of said mixture between about 3 1/2 to 15 hours after step 1(c) to detect a given increase in fluorescence intensity; and
  - 25 e. comparing said detected fluorescence intensity with changes in fluorescence intensity of a control to determine susceptibility to antimicrobial agents of said Gram positive organisms.
2. The method of Claim 1 where said control consist of a growth control an a buffer control.
- 30

3. The method of Claim 1 wherein said Gram positive organisms are selected from the class consisting of: *Staphylococcus aureus*, *S.cohnii*, *S.epidermidis*, *S.haemolyticus*, *S.hominis*, *S.hyicus-hyicus*, *S.intermedius*, *S.lentus*, *S.saprophyticus*, *S.sciuri*, *S.similans*, *S.xylosus*, *S.kloosii*, *S.caseolyticus*, *S.chromogenes*, *S.carnosus*, *S.caprae*, and *S.gallinarum*, *Streptococcus pyogenes* (Group A), *St.agalactiae* (Group B), *St.equi/equismilis*, *St.zooepidemicus*, *St.bovis I*, *St.bovisII*, *St.equinus*, *St.mutans*, *St.sanguis I*, *St.sanguis II*, *St.anginosus/milleri*, *St.constellatus/milleri*, *St.intermedius/milleri*, *St.mitis*, *St.morbilorum*, *St.salivarius*, *St.pneumoniae*, *Enterococcus faecalis*, *Ec.faecium*, *Ec.durans*, *Ec.avium*, and *Listeria monocytogenes*.
4. The method of Claim 1 wherein said antimicrobial agent is selected from the class consisting: Amoxicillin/K Clavulanate, Ampicillin, Ampicillin/Sulbactam, Cefamandole, Cefazolin, Cefotaxime, Ceftriaxone, Cefuroxime, Cephalothin, Chloramphenicol, Ciprofloxacin, Clindamycin, Erythromycin, Gentamicin, Gentamicin Synergy Screen, Imipenem, Nitrofurantoin, Norfloxacin, Oxacillin, Penicillin, Rifampin, Streptomycin Synergy Screen, Tetracycline, Trimethoprim, Trimethoprim/Sulfamethoxazole and Vancomycin.

5. Method for determining susceptibility to antimicrobial agents of the majority of clinically significant Gram positive organisms comprising:
- 5 a. suspending and homogenously mixing a sufficient number of morphologically similar colonies of Gram positive organism in an aqueous suspending medium to prepare an inoculum having a turbidity equivalent to at least 0.5 McFarland barium sulfate turbidity standard;
  - 10 b. diluting said inoculum in a sufficient amount of growth supporting medium to achieve a nominal concentration of about  $2 \times 10^6$  colony forming units/mL;
  - 15 c. combining a portion of said inoculum with a sufficient amount of fluorogenic substrates consisting of: leucine-7-amido-4-methylcoumarin, phenylalanine-7-amido-4-methylcoumarin and 4-methylumbelliferyl phosphate, a predetermined amount of an antimicrobial agent, and sufficient amounts of buffer to stabilize said fluorogenic substrate in individual microwell dilution compartments to form antimicrobial agent wells;
  - 20 d. combining a portion of said inoculum with a sufficient amount of fluorogenic substrates consisting of: leucine-7, amido-4-methylcoumarin, phenylalanine-7-amido-4-methylcoumarin and 4-methylumbelliferyl phosphate and a sufficient amount of buffer to stabilize said fluorogenic substrate in other individual microwell dilution compartments to form growth wells;
  - 25 e. combining a portion of said inoculum with a sufficient amount of buffer to stabilize said fluorogenic substrate in individual microwell dilution compartments to form control wells.

- f. repeatedly monitoring fluorescence intensity of said wells between about 3 1/2 to 15 hours after steps (c), (d) and (e); and
- g. comparing said detected fluorescence intensities of said antimicrobial agent wells with said growth wells and control well to determine susceptibility to antimicrobial agent of said Gram positive organisms.
- 5
6. The method of Claim 5 wherein said Gram positive organisms are selected from the class consisting of: *Staphylococcus aureus*, *S.cohnii*, *S.epidermidis*, *S.haemolyticus*, *S.hominis*,  
10 *S.hyicus-hyicus*, *S.intermedius*, *S.lentus*, *S.saprophyticus*, *S.sciuri*, *S.similans*, *S.xylosus*, *S.kloosii*, *S.caseolyticus*, *S.chromogenes*, *S.carnosus*, *S.caprae*, and *S.gallinarum*, *Streptococcus pyogenes* (Group A), *St.agalactiae* (Group B),  
15 *St.equi/equismilis*, *St.zooepidemicus*, *St.bovis I*, *St.bovisII*, *St.equinus*, *St.mutans*, *St.sanguis I*, *St.sanguis II*, *St.anginosus/milleri*, *St.constellatus/milleri*, *St.intermedius/milleri*, *St.mitis*, *St.morbillosum*, *St.salivarius*, *St.pneumoniae*, *Enterococcus faecalis*,  
20 *Ec.faecium*, *Ec.durans*, *Ec.avium*, and *Listeria monocytogenes*.
7. The method of Claim 5 wherein said antimicrobial agent is selected from the class consisting: Amoxicillin/K  
Clavulanate, Ampicillin, Ampicillin/Sulbactam, Cefamandole,  
25 Cefazolin, Cefotaxime, Ceftriaxone, Cefuroxime, Cephalothin, Chloramphenicol, Ciprofloxacin, Clindamycin, Erythromycin, Gentamicin, Gentamicin Synergy Screen, Imipenem, Nitrofurantoin, Norfloxacin, Oxacillin, Penicillin, Rifampin, Streptomycin Synergy Screen, Tetracycline,  
30 Trimethoprim, Trimethoprim/Sulfamethoxazole and Vancomycin.

8. A kit to conduct the method of Claim 1 comprising control, growth control, and antimicrobial agents in individualized compartments, said control compartments containing buffer, said growth control compartments containing buffer and fluorogenic concentrate and said antimicrobial agent compartment containing buffer, antimicrobial agent and fluorogenic concentrate.
- 5
9. The kit of Claim 8 wherein said fluorogenic substrates are concentrated.
- 10
10. The kit of Claim 8 where kit reagents are dehydrated.
- 15
- 20
- 25

V.  OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE<sup>1</sup>

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1.  Claim numbers , because they relate to subject matter (1) not required to be searched by this Authority, namely:

2.  Claim numbers , because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out (1), specifically:

3.  Claim numbers , because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI.  OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING<sup>2</sup>

This International Searching Authority found multiple inventions in this international application as follows:

1.  As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2.  As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3.  No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4.  As all searchable claims could be searched without effort justifying an additional fee, the International Search Authority did not invite payment of any additional fee.

Remark on protest

The additional search fees were accompanied by applicant's protest.

No protest accompanied the payment of additional search fees.

| III. DOCUMENTS CONSIDERED TO BE RELEVANT (CONTINUED FROM THE SECOND SHEET) |                                                                                                                                                                           |                                     |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| Category*                                                                  | Citation of Document, <sup>16</sup> with indication, where appropriate, of the relevant passages <sup>17</sup>                                                            | Relevant to Claim No. <sup>18</sup> |
| A                                                                          | Journal of Clinical Microbiology, Volume 26 No. 1, issued January 1988, Staneck et al, "Rapid MIC Testing with the Sensititre Autoreader" pages 1-7, see entire document. | 1-10                                |
