(57) **ABSTRACT**

An optical communication system that includes a multi-channel post amplifier assembly with flexible output configurations for amplifying optical-to-electrical converted signals on selectable groups of amplifier channels is provided. The post amplifier assembly, when implemented on a single IC chip, is capable of operating with either the 2.5V or 3.3V of power supply. In addition, the IC chip containing the post amplifier assembly provides capability to selectively turn off one or more post amplifier channels during operation. Further, the post amplifiers provide integral auto zero function without requiring a use of external capacitors.

## POST AMPLIFIER ARRAY INTEGRATED CIRCUIT

### BACKGROUND OF THE INVENTION

The present invention relates most generally to the field of transmission and reception of information on optical fibers. More particularly, the present invention relates to an integrated circuit apparatus and method for post amplifying signals received over the optical fibers that are subsequently converted to electrical signals.

In the field of telecommunications, lasers such as vertical cavity surface emitting lasers (VCSELs) and other optoelectronic devices are commonly used for the transmission of information along optical fibers and the like as optical signals. VCSELs, in particular are especially desirable in today's optical communication systems because they are efficient, small in size, readily assembled into arrays, and easy to manufacture.

At the receiving end, the optical signals that are transmitted by the optical fibers are converted by optical detectors into electrical signals, and then post amplified by post amplifiers to increase the voltage level output of the converted electrical signals. Conventional post amplifier circuitry used for amplifying the electrical signals typically works with an input power supply that is restricted to only a single voltage level, and different post amplifier circuits are typically designed for use in systems that have different system voltages.

Further, conventional post amplifier circuits, when implemented on an integrated circuit (IC) chip, do not include the capability to turn on only the relevant portion of the IC chip. Thus, when multiple post amplifier channels are integrated on a single IC chip, all of the amplifiers on all of the channels must be activated. Therefore, the power supplied to the unused channels is wasted, often forcing designers to separate various post amplifier circuits onto separate IC chips that are each tailored to include only those post amplifier channels that will be used for each discrete application. Ultimately, this leads to increase in the number of different types of IC chips that are needed and requires the design and fabrication of multiple post amplifier IC chips instead of one-design-fits-all type of approach.

Another issue with the post amplifiers known in the prior art is that they typically have auto zero function, which is designed to maintain the dc level of the input signals (optical-to-electrical converted signals). Conventional post amplifier circuitry (on an IC chip) typically uses an external capacitor to implement this auto zero function. External capacitors take up space, and its use is undesirable, especially when a post amplifier array is implemented on a single IC chip.

It would therefore be desirable to provide an arrayed post amplifier assembly on a single IC chip with a portion that can be selectively turned off during operation. Further it is desirable to provide a post amplifier assembly that can work with voltage supplies at multiple voltage levels and does not require a use of external capacitors to implement the auto zero function.

### BRIEF SUMMARY OF THE INVENTION

In this regard, the present invention provides for an optical communication system that includes a multi-channel post amplifier assembly with flexible output configurations for amplifying optical-to-electrical converted signals on selectable groups of amplifier channels is provided. The post

2

amplifier assembly, when implemented on a single IC chip, is capable of operating with either the 2.5V or 3.3V of power supply therefore allowing integration of the chip into various devices that have different power supply requirements. This feature enhances the modularity of the present invention in that only one IC post amplifier design needs to be manufactured to handle a variety of applications.

In addition, the IC chip containing the post amplifier assembly provides capability to selectively turn off one or more post amplifier channels during operation. Preferably, the post amplifier array is divided into two or more groups. Each of the groups of post amplifier channels and the associated overhead operational circuitry are separated from the power supply by a switch. This architecture allows the switch to be selectively operated to energize additional groups of amplifier channels as the demand for channels increases while turning them off during low demand periods to reduce the power consumption of the device.

Further, the post amplifiers provide integral auto zero function without requiring a use of external capacitors. This is accomplished by providing integrally formed circuitry for each amplifier channel onto the IC chip with the amplifier circuitry. In this manner the footprint of the overall assembly is greatly reduced while the performance is maintained.

It is therefore an object of the present invention to provide a novel array of post amplifier circuits that can be integrated onto a single IC chip in a modular manner for flexible integration. Further it is an object of the present invention to provide a compact and flexible functionality in that only the required number of channels necessary to operate the desired function or at the desired bandwidth must be energized thereby saving on the power consumption of the system during lower demand operations. It is yet another object of the present invention to create a single modular post amplifier IC design to be integrated into various different component systems while reducing overall design and manufacturing costs, resulting from prior art one-off design techniques.

Other objects, features and advantages of the invention shall become apparent as the description thereof proceeds when considered in connection with the accompanying illustrative drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings which illustrate the best mode presently contemplated for carrying out the present invention:

FIG. 1 is a block diagram of an optical receiver array including a post amplifier array in an embodiment according to the present invention;

FIG. 2 is a circuit diagram of post amplifier circuitry in an embodiment according to the present invention; and

FIG. 3 is a circuit diagram of circuitry that provides slow discharge of transistor base leakage in an embodiment according to the present invention.

### DETAILED DESCRIPTION OF THE INVENTION

#### I. Overview

Referring now to the drawings, FIG. 1 is a block diagram of an optical receiver array 100 in one embodiment of the present invention. The optical receiver array 100 includes a post amplifier array 102 and optical detector arrays 110 and 112 to receive multi-channel optical signals. Each of the optical detector arrays 110 and 112 may represent one or

more optical detectors. For example, as illustrated in FIG. 1, the optical detector array **110** represents eight optical detectors for interfacing with post optical detector arrays **110** and **112** may include different number of optical detectors, and the total number of optical detectors used may be different from twelve.

Each one of the post amplifier channels **1–12** may be used for high speed data receiving. For example, in this embodiment, each channel is capable of receiving up to 2.5 Gigabits per second (Gbps) of data. In other embodiments, the post amplifier channels may be used to receive data at a rate that is even higher than 2.5 Gbps.

In practice, the optical receiver array **100** includes a transimpedance amplifier (TIA) (not shown) that corresponds to each post amplifier channel **1–12** since the optical detectors typically generate current as output. The TIAs, therefore, preferably are used to convert the current output of the optical detectors into a voltage signal that is supplied to the post amplifier array **102**.

## II. Optional Power Supply Alternatives of 2.5 Volt and 3.3 Volt

The post amplifier array **102** preferably is implemented on a single integrated circuit (IC) chip for reduction of space it occupies in the overall optical receiver array **100**. The TIAs that are coupled to the photo detectors may be implemented on the same IC chip or they may be implemented externally to the IC chip containing the post amplifier array **102**. The post amplifier array **102** (on a single IC chip) is capable of operating with a power supply **101** of either 2.5V or 3.3V. While power and heat dissipation is reduced when the 2.5V power supply **101** is applied to the IC chip as compared to when the 3.3V power supply **101** is used. The ability for the IC chip to operate using a 3.3V power supply **101** allows the post amplifier array **102** to work together with other IC chips in an overall system that utilizes a 3.3V power supply **101**. This eliminates the need for a DC-to-DC power conversion means or use of an additional 2.5V power supply to provide power to the post amplifier array **102**. In other embodiments, the supply voltage levels **101** that the post amplifier array **102** is capable of working with may be different from 2.5V and/or 3.3V disclosed herein. Further, the post amplifier array **102** may also be able to operate in a system having more than two different supply voltage levels **101**.

## III. The Post Amplifier Array Power Down Feature

The post amplifier array **102** of the present includes a power down feature. The post amplifier array **102** of the exemplary embodiment shown in FIG. 1 includes a first group of post amplifiers **104**, a second group of post amplifiers **106** and a power down select switch **108**. The first group of post amplifiers **104** includes an array of post amplifiers corresponding to eight post amplifier channels **1–8**. The second group of post amplifiers **106** includes an array of four post amplifiers corresponding for four post amplifier channels **9–12**. Each group of post amplifiers **104** and **106** includes the required overhead circuitry to perform necessary associated overhead functions that are preferably shared by all post amplifiers in the group. Clearly, the number of post amplifiers in each group **104** and **106** of post amplifiers may be different in other embodiments as may be required for the particular application into which the post amplifier array **102** may be incorporated. Further, the total number of post amplifiers may be different from twelve. The number of channels, eight in one group **104** and four in another group **106**, for a total of twelve channels, is simply an example. It can be appreciated that additional configura-

tions having more groups with more or less channels per group would still fall within the principles and disclosure of the present invention.

The first group of post amplifiers **104** and the associated overhead circuitry is coupled directly to the power supply **101**. However, the second group of post amplifiers **106** and the associated overhead circuitry is coupled to the power supply **101** via the power down select switch **108**. Power down select signals **109** are provided to the power down select switch **108** to open and close the switch **108** thereby selectively energizing the post amplifier channels in the secondary group **106** on the post amplifier array **102**.

During normal operation, the first group of post amplifiers **104** and the associated overhead circuitry always receive power from the power supply **101** and are therefore always active. When the power down select switch **108** is in the closed position, the power supply **101** also provides power to the second group of post amplifiers **106** and the associated overhead circuitry, allowing the second group of amplifiers **106** energize and interface with four channels of additional electrical signals from the secondary photodetector array **112**. When the power down select switch **108** is open, however, the second group of post amplifiers **106** and the associated overhead circuitry are not powered, thereby reducing the overall power consumption of the overall post amplifier array **102** when the secondary array of photodetectors **112** are not active.

With this option for selectively controlling the power **101** supplied to one or more of the post amplifier channels in the post amplifier array **102**, power may be saved when less than all the post amplifiers in the post amplifier array **102** are needed to meet post amplifying needs for low power dissipation or low bandwidth applications. At the same time, availability of the additional post amplifier channels allows for a flexible design so that a single post amplifier array **102** in a single IC chip design may be used for multiple different applications allowing the flexibility to handle higher bandwidth applications when the need arises.

In the post amplifier array **102** shown in FIG. 1, there are total of twelve post amplifier channels in two groups **104**, **106**. One group **106** of post amplifiers includes four channels that may be selectively turned on and off as necessary using signals **109** that are transmitted to power down select switch **108**. In other embodiments, there may be more or less than twelve post amplifiers in the post amplifier array. In addition, the number of post amplifiers that may be switched off and on may be different. For example, the post amplifier array may include eight, twelve or any other suitable number of post amplifiers. Further, other embodiments may include more than one power down select switch to switch more than one group of post amplifiers on and off.

The post amplifier array **102** with selective power down feature may be applied to various different types of receiver array circuits **110**, **112** including but not limited to long wave VCL (vertical cavity laser) receiver array circuits, shortwave VCL receiver array circuits and distributed feedback (DFB) laser receiver array circuits.

The present invention provides the ability to produce a post amplifier array **102** in a modular manner wherein modular arrays having multiple groups, each group containing multiple post amplifier channels create flexible post amplifier IC chips. Therefore a single post amplifier chip could be manufactured that could serve the needs of applications ranging from single post amplifier channels to as many as 24 post amplifier channels for example in flexible channel step configurations of 4, 8, 12, 16, 20 and 24 simultaneous operational channels. Similarly, channels

could be grouped by 2, 4, 6 or 8. These examples are provided simply as examples and are for illustration and are not considered as limitations on the range of possible configurations that the present invention may take. In many system applications, use of a single modular part rather than multiple different parts, each having an array that includes a different number of post amplifiers in the post amplifier array will result in cost reduction and reduction of manufacturing management needs due to production of greater volume for a single part.

The power down function for the post amplifier array IC **102** allows for the selective shut down of unused channels and nonessential overhead functions. As a way of an additional illustrative example, four channels **106** may be disabled from a 12 channel IC **102** that requires only eight channels **104** for the specific application that is currently being processed. This allows for one IC **102** to be used for multiple applications taking advantage of economy of scales and simplified manufacturing processes.

#### IV. Internal Auto Zero Capacitor—Implementation Using Slow Discharge of Transistor Base Leakage Current

Turning now to FIG. 2, a circuit diagram of a post amplifier **200** in an embodiment according to the present invention is illustrated. The post amplifier **200** is implemented using bipolar transistors as can be seen in FIG. 2. The bipolar transistors typically provide better performance at high frequency operations than CMOS transistors. Further, CMOS transistors typically consume more power at high frequencies to obtain the same bandwidth as the bipolar transistors. In other embodiments, however, other types of transistors, such as, for example, MOSFETs (Metal-Oxide-Silicon Field Effect Transistors) or JFETs (Junction Field Effect Transistors) may be used to implement the post amplifier circuit **200**.

The post amplifier **200** preferably receives a differential input **206**, which may be provided over any one of the post amplifier channels 1–12 of FIG. 1. The post amplifier **200** includes resistors **202** and **204**, respectively, between the power supply  $V_{cc}$  and collectors of input transistors **208** and **210**. The resistors **202** and **204** serve to regulate and apply the correct voltage from the power supply  $V_{cc}$  to the transistors **208** and **210**. The collectors of the input transistors **208** and **210** receive the differential input **206**. As can be seen in FIG. 2, the input transistors **208** and **210** are NPN bipolar transistors. In other embodiments, PNP bipolar transistors may also be used as the input transistors.

Emitters of the input transistors **208** and **210** are coupled to a current source **212**, which supplies a reference current  $I_{ref}$ . Bases of the input transistors **208** and **210** provide a differential output to collectors of output transistors **224** and **226**. The output transistors **224** and **226** are NPN bipolar transistors. In other embodiments, PNP transistors may be used as the output transistors. Emitters of the output transistors **224** and **226** are coupled to a current source **228**, which provides a reference current  $I_{ref}$ . Design of the circuitry to provide the desired reference current  $I_{ref}$  as described with respect to both current supply **212** and **228** is well known to those skilled in the art.

The emitters of the output transistors **224** and **226** are also coupled to an inverting terminal of an operational amplifier (op amp) **230**. A non-inverting terminal of the op amp **230** is coupled to a reference voltage  $V_{ref}$ , and the output of the op amp **230** is connected to the bases of gain control transistors **220** and **222**, which are PNP bipolar transistors. In other embodiments, the gain control transistors may be

NPN transistors. Design of the circuitry to provide the reference voltage  $V_{ref}$  is well known to those skilled in the art.

Emitters of the gain control transistors **220** and **222** are coupled to the power supply  $V_{cc}$ . Collectors of the gain control transistors **220** and **222** are coupled to the collectors of the output transistors **224** and **226**, respectively. Bases of the output transistors **224** and **226** provide a differential output **232** of the post amplifier **200**.

In accordance with the principles of the present invention, an auto zero circuit **214** is integrally included into the post amplifier circuitry **200** and is coupled between the differential output (bases) of the input transistors **208** and **210**. The auto zero circuit **214** provides the auto zero function that would be provided by an equivalent capacitor **216** that in the prior art would be an external element. The auto zero function maintains the dc level of the differential input signal. If the dc component of the differential input signal sways from zero, the auto zero function preferably compensates the input signal to return the dc component of the input signal to zero.

Conventional IC chips containing a post amplifier typically use an external capacitor (to the IC chip) to implement the auto zero function described herein. Use of the external capacitor is undesirable due to space limitations, and it is a particularly important issue when a post amplifier array is implemented on a single IC chip since an individual external capacitor is necessary for each post amplifier that corresponds to each channel contained thereon. The auto zero circuit **214** performs the function of an external capacitor (as indicated by the equivalent capacitor **216**) in this embodiment according to the present invention.

Turning now to FIG. 3 the auto zero circuit **214** as it would operate using an equivalent capacitor **216** in the prior art and a circuit diagram showing an auto zero circuit **250** that is an internal replacement for the external auto zero circuit **214** in an embodiment according to the present invention. The auto zero circuit **250** includes a non-inverted differential circuit including an input transistor **262**, a signal accumulation capacitor **264**, an auto zeroing transistor **266** and a current source **268**. Similarly, the auto zero circuit **250** also includes an inverted differential circuit including an input transistor **252**, a signal accumulation capacitor **254**, an auto zeroing transistor **256** and a current source **258**. The input transistors **252**, **262** and the auto zeroing transistors **256**, **266** in this embodiment are bipolar NPN transistors. In other embodiments, the input transistors and the auto zeroing transistors may be PNP transistors. The base leakage currents of the auto zeroing transistors **256** and **266**, respectively, are used to perform the auto zero function for the inverted and non-inverted inputs, respectively. Since both the inverted differential circuit and the non-inverted differential circuit has identical configuration, the auto zero circuit **250** will be described only in reference to the non-inverted differential circuit, hereinafter.

The base of the input transistor **262** preferably receives a non-inverted input signal from, for example, the input transistor **208** of FIG. 2. The base of the input transistor **262** is also coupled to ground via the signal accumulation capacitor **264** to decrease the impedance at this point in the circuit. Collectors of the input transistor **262** and the auto zeroing transistor **266** are coupled to the power supply  $V_{cc}$ . The emitter of the input transistor **262** provides an output voltage at a base of the auto zeroing transistor **266**. The emitter of the auto zeroing transistor **266** is coupled to a current source **268**. The current source **268** is coupled to ground. The current source **268** in FIG. 3 provides 1 mA of

7

current. The current sources in other embodiments may provide currents with other magnitude as would be appreciated by those skilled in the art.

The base of the auto zeroing transistor **266** and the emitter of the input transistor **262** are provided as the output of the auto zero circuit **250**. For example, when the dc component of the output portion provided by the input transistor **262** strays from zero, the base leakage current from the auto zeroing transistor **266** preferably adjusts the dc components to zero voltage.

It should be emphasized that the above-described embodiments are intended to be exemplary only. The specific arrangement of the components of the integrated circuit and the details of the method generally covered by the integrated circuit, are exemplary only. The integrated circuit including the post amplifier array of the present invention may be integrated into larger integrated circuits including other features, without departing from the scope of the present invention.

It can therefore be seen that the present invention provides a novel array of post amplifier that can be integrated onto a single IC chip in a modular manner for flexible integration. Further the present invention provides compact and flexible functionality in that only the required number of channels necessary to operate the desired function or at the desired bandwidth must be energized thereby saving on the power consumption of the system during lower demand operations. Further this allows a single modular post amplifier IC design to be integrated into various different component systems while reducing overall design and manufacturing costs resulting from prior art one-off design techniques. For these reasons, the instant invention is believed to represent a significant advancement in the art, which has substantial commercial merit.

While there is shown and described herein certain specific structure embodying the invention, it will be manifest to those skilled in the art that various modifications and rearrangements of the parts may be made without departing from the spirit and scope of the underlying inventive concept and that the same is not limited to the particular forms herein shown and described except insofar as indicated by the scope of the appended claims.

What is claimed:

1. A post amplifier array implemented on an integrated circuit (IC) chip for use in optical communications applications, the post amplifier array comprising:

a plurality of post amplifiers disposed on a single integrated chip; and

an array of optical detectors for receiving optical signals and converting said optical signals to electronic data signals, said optical detectors in electronic communication with said plurality of post amplifiers,

wherein said plurality of post amplifiers receive said electronic data signals from said array of optical detectors, amplify the received data signals, and output the amplified data signals, wherein the post amplifiers are capable of operating one of a plurality of preselected and preset input voltage levels.

2. The post amplifier array of claim 1, wherein the different input voltage levels are approximately 2.5V and 3.3V.

3. The post amplifier array of claim 1, further comprising: said plurality of post amplifiers organized into first and second groups; and

a switch located between the second group of post amplifiers and an input power supply, wherein said first group of the post amplifiers is always electrically

8

coupled to the input power supply to receive power during normal operation, and wherein the second group of post amplifiers are selectively electrically coupled to the input power supply to receive power only when the switch is turned on.

4. The post amplifier array of claim 3, wherein each of the first and second groups of post amplifiers is associated with overhead function circuitry, wherein the overhead circuitry associated with the first group always receives power during normal operation, and wherein the overhead circuitry associated with the second group receives power only when the switch is turned on.

5. The post amplifier array of claim 3, wherein the first group includes eight post amplifiers and the second group includes four post amplifiers.

6. The post amplifier array of claim 1, further comprising: auto zero circuitry integrally connected to each individual post amplifier for performing an auto zero function of zeroing the dc component of the received data signals, wherein the auto zero circuitry does not require the use of an external capacitor to perform the auto zero function.

7. The post amplifier array of claim 6, wherein the auto zero circuitry includes a transistor, said transistor having a base, wherein leakage current from said base is used to perform the auto zero function.

8. The post amplifier array of claim 3, further comprising: auto zero circuitry integrally connected to each individual post amplifier for performing an auto zero function of zeroing the dc component of the received data signals, wherein the auto zero circuitry does not require the use of an external capacitor to perform the auto zero function.

9. The post amplifier array of claim 8, wherein the auto zero circuitry includes a transistor, said transistor having a base, wherein leakage current from said base is used to perform the auto zero function.

10. A post amplifier array implemented on an integrated circuit (IC) chip, the post amplifier array comprising:

a plurality of individual post amplifiers, each post amplifier capable of receiving a data signal, amplifying the received data signal, and outputting the amplified data signal, the individual post amplifiers being organized into first and second groups; and

a switch located between the Second group of post amplifiers and an input power supply, wherein said first group of the post amplifiers is always electrically coupled to the input power supply to receive power during normal operation, and wherein the second group of post amplifiers are selectively electrically coupled to the input power supply to receive power only when the switch is turned on.

11. The post amplifier array of claim 10, wherein each of the first and second groups of post amplifiers is associated with overhead function circuitry, wherein the overhead circuitry associated with the first group always receives power during normal operation, and wherein the overhead circuitry associated with the second group receives power only when the switch is turned on.

12. The post amplifier array of claim 10, wherein the first group includes eight post amplifiers and the second group includes four post amplifiers.

13. The post amplifier array of claim 10, wherein the post amplifiers are capable of operating with multiple different input voltage levels.

9

**14.** The post amplifier array of claim **13**, wherein the different input voltage levels are approximately 2.5V and 3.3V.

**15.** The post amplifier array of claim **10**, further comprising:

auto zero circuitry integrally connected to each individual post amplifier for performing an auto zero function of zeroing the dc component of the received data signals, wherein the auto zero circuitry does not require the use of an external capacitor to perform the auto zero function.

**16.** The post amplifier array of claim **15**, wherein the auto zero circuitry includes a transistor, said transistor having a base, wherein leakage current from said base is used to perform the auto zero function.

**17.** A post amplifier implemented on an integrated circuit (IC) chip, the post amplifier comprising:  
input means for receiving data signals;  
amplifying means for amplifying the received data signals;

10

output means for transmitting the amplified data signals;  
and

auto zero circuitry for performing an auto zero function of zeroing the dc component of the received data signals, wherein the auto zero circuitry does not require the use of an external capacitor to perform the auto zero function.

**18.** The post amplifier of claim **17**, wherein the auto zero circuitry comprises a transistor, said transistor having a base, wherein leakage current from said base is used to perform the auto zero function.

**19.** The post amplifier of claim **17**, wherein the post amplifier is capable of operating with multiple different input voltage levels.

**20.** The post amplifier of claim **17**, wherein the different input voltage levels are approximately 2.5V and 3.3V.

\* \* \* \* \*
