DETAILED DESCRIPTION

[0042] As will be appreciated by one skilled in the art, aspects of the embodiments may be embodied as a system, apparatus, method, or program product. Accordingly, embodiments may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may all generally be referred to herein as a "circuit," "module" or "system." Furthermore, embodiments may take the form of a program product embodied in one or more computer readable storage devices storing machine readable code, computer readable code, and/or program code, referred to hereafter as code. The storage devices may be tangible, non-transitory, and/or non-transmission. The storage devices may not embody signals. In a certain embodiment, the storage devices only employ signals for accessing code.

[0043] Certain of the functional units described in this specification may be labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom very-large-scale integration ("VLSI") circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in
5 programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

[0044] Modules may also be implemented in code and/or software for execution by various types of processors. An identified module of code may, for instance, include one or
10 more physical or logical blocks of executable code which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module need not be physically located together, but may include disparate instructions stored in different locations which, when joined logically together, include the module and achieve the stated purpose for the module.

[0045] Indeed, a module of code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may
20 be distributed over different locations including over different computer readable storage devices. Where a module or portions of a module are implemented in software, the software portions are stored on one or more computer readable storage devices.

[0046] Any combination of one or more computer readable medium may be utilized. The computer readable medium may be a computer readable storage medium. The computer readable
25 storage medium may be a storage device storing the code. The storage device may be, for example, but not limited to, an electronic, magnetic, optical, electromagnetic, infrared, holographic, micromechanical, or semiconductor system, apparatus, or device, or any suitable combination of the foregoing.

[0047] More specific examples (a non-exhaustive list) of the storage device would
30 include the following: an electrical connection having one or more wires, a portable computer diskette, a hard disk, a random access memory ("RAM"), a read-only memory ("ROM"), an erasable programmable read-only memory ("EPROM" or Flash memory), a portable compact disc read-only memory ("CD-ROM"), an optical storage device, a magnetic storage device, or any suitable combination of the foregoing. In the context of this document, a computer readable

storage medium may be any tangible medium that can contain, or store a program for use by or in connection with an instruction execution system, apparatus, or device.

[0048] Code for carrying out operations for embodiments may be any number of lines and may be written in any combination of one or more programming languages including an object oriented programming language such as Python, Ruby, Java, Smalltalk, C++, or the like, and conventional procedural programming languages, such as the "C" programming language, or the like, and/or machine languages such as assembly languages. The code may execute entirely on the user's computer, partly on the user's computer, as a stand-alone software package, partly on the user's computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user's computer through any type of network, including a local area network ("LAN") or a wide area network ("WAN"), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

[0049] Reference throughout this specification to "one embodiment," "an embodiment," or similar language means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment. Thus, appearances of the phrases "in one embodiment," "in an embodiment," and similar language throughout this specification may, but do not necessarily, all refer to the same embodiment, but mean "one or more but not all embodiments" unless expressly specified otherwise. The terms "including," "comprising," "having," and variations thereof mean "including but not limited to," unless expressly specified otherwise. An enumerated listing of items does not imply that any or all of the items are mutually exclusive, unless expressly specified otherwise. The terms "a," "an," and "the" also refer to "one or more" unless expressly specified otherwise.

[0050] Furthermore, the described features, structures, or characteristics of the embodiments may be combined in any suitable manner. In the following description, numerous specific details are provided, such as examples of programming, software modules, user selections, network transactions, database queries, database structures, hardware modules, hardware circuits, hardware chips, etc., to provide a thorough understanding of embodiments. One skilled in the relevant art will recognize, however, that embodiments may be practiced without one or more of the specific details, or with other methods, components, materials, and so forth. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of an embodiment.

[0051] Aspects of the embodiments are described below with reference to schematic flowchart diagrams and/or schematic block diagrams of methods, apparatuses, systems, and

program products according to embodiments. It will be understood that each block of the schematic flowchart diagrams and/or schematic block diagrams, and combinations of blocks in the schematic flowchart diagrams and/or schematic block diagrams, can be implemented by code. The code may be provided to a processor of a general purpose computer, special purpose
5 computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

[0052] The code may also be stored in a storage device that can direct a computer, other
10 programmable data processing apparatus, or other devices to function in a particular manner, such that the instructions stored in the storage device produce an article of manufacture including instructions which implement the function/act specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

[0053] The code may also be loaded onto a computer, other programmable data
15 processing apparatus, or other devices to cause a series of operational steps to be performed on the computer, other programmable apparatus or other devices to produce a computer implemented process such that the code which execute on the computer or other programmable apparatus provide processes for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

[0054] The schematic flowchart diagrams and/or schematic block diagrams in the Figures
20 illustrate the architecture, functionality, and operation of possible implementations of apparatuses, systems, methods and program products according to various embodiments. In this regard, each block in the schematic flowchart diagrams and/or schematic block diagrams may represent a module, segment, or portion of code, which includes one or more executable
25 instructions of the code for implementing the specified logical function(s).

[0055] It should also be noted that, in some alternative implementations, the functions
noted in the block may occur out of the order noted in the Figures. For example, two blocks shown in succession may, in fact, be executed substantially concurrently, or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved. Other
30 steps and methods may be conceived that are equivalent in function, logic, or effect to one or more blocks, or portions thereof, of the illustrated Figures.

[0056] Although various arrow types and line types may be employed in the flowchart and/or block diagrams, they are understood not to limit the scope of the corresponding
embodiments. Indeed, some arrows or other connectors may be used to indicate only the logical

flow of the depicted embodiment. For instance, an arrow may indicate a waiting or monitoring period of unspecified duration between enumerated steps of the depicted embodiment. It will also be noted that each block of the block diagrams and/or flowchart diagrams, and combinations of blocks in the block diagrams and/or flowchart diagrams, can be implemented by special purpose hardware-based systems that perform the specified functions or acts, or combinations of special purpose hardware and code.

Although only one transmitter 210 and one receiver 212 are illustrated, the remote unit 102 may have any suitable number of transmitters 210 and receivers 212. The transmitter 210 and the receiver 212 may be any suitable type of transmitters and receivers. In one embodiment, the transmitter 210 and the receiver 212 may be part of a transceiver.

[0072] Figure 3 depicts one embodiment of an apparatus 300 that may be used for determining a TPMI for a codebook set. The apparatus 300 includes one embodiment of the base unit 104. Furthermore, the base unit 104 may include a processor 302, a memory 304, an input device 306, a display 308, a transmitter 310, and a receiver 312. As may be appreciated, the processor 302, the memory 304, the input device 306, the display 308, the transmitter 310,

and the receiver 312 may be substantially similar to the processor 202, the memory 204, the input device 206, the display 208, the transmitter 210, and the receiver 212 of the remote unit 102, respectively.

[0073] In some embodiments, the receiver 312 may receive information indicating a transmission capability of a remote unit 102. In various embodiments, the processor 302 may determine a transmit precoding matrix indication based on a rank and a codebook corresponding to the transmission capability and the rank, wherein the transmit precoding matrix indication corresponding to a rank of one includes a maximum of five bits, the transmit precoding matrix indication corresponding to a rank of two includes a maximum of four bits, and the transmit precoding matrix indication corresponding to a rank of three includes a maximum of three bits. In certain embodiments, the transmitter 310 may transmit the transmit precoding matrix indication to the remote unit 102. Although only one transmitter 310 and one receiver 312 are illustrated, the base unit 104 may have any suitable number of transmitters 310 and receivers 312. The transmitter 310 and the receiver 312 may be any suitable type of transmitters and receivers. In one embodiment, the transmitter 310 and the receiver 312 may be part of a transceiver.

[0074] In certain embodiments, such as for full-coherent transmission a codebook may be as found in Table 1.

[0075] As found in Table 1, $W_n^{(s)}$ denotes the matrix defined by the columns given by the set $\{s\}$ from the expression $W_n = I - 2u_n u_n^H / u_n^H u_n$ where I is a 4×4 identity.

5 [0076] In some embodiments, such as for partial coherent transmission, a codebook for rank 1 (e.g., 1 layer) is found in Table 2, a codebook for rank 2 (e.g., 2 layers) is found in Table 3, a codebook for rank 3 (e.g., 3 layers) is found in Table 4, and a codebook for rank 4 (e.g., 4 layers) is found in Table 5. In certain embodiments, out of 4 ports, the ports may be pair-wise coherent (e.g., coherent within a pair of two ports, but non-coherent between pairs of ports). For example, there may be transmission coherency between ports one and two and between ports 10 three and four, but not between ports one and three and not between ports two and four. As another example, there may be transmission coherency between ports one and three and between ports two and four, but not between ports one and two and not between ports three and four.

[0078] In various embodiments, a remote unit 102 may report its coherent transmission capability to a base unit 104. As set forth above, different coherent transmission capabilities may correspond to different codebook tables. For example, full-coherent transmission capability may correspond to the codebook found in Table 1. As another example, partial-coherent transmission capability may correspond to the codebooks found in Table 2, Table 3, Table 4, and Table 5. As a further example, non-coherent transmission capability may correspond to Table 6, Table 7, Table 8, and Table 9.

[0079] In some embodiments, the base unit 104 may determine (e.g., calculate) TPMIs based on different codebook Tables corresponding to different remote unit 104 coherent transmission capabilities for PUSCH transmission.

[0080] In one embodiment of partial-coherent transmission, the base unit 104 may use a full TPMI indication. In such an embodiment, the base unit 104 may directly determine TPMIs based on Table 2, Table 3, Table 4, and Table 5. Furthermore, in such an embodiment, 5 bits

may be used for each TPMI for rank 1, 4 bits may be used for each TPMI for rank 2, and 3 bits may be used for each TPMI for rank 3.

[0081] In another embodiment of partial-coherent transmission, the base unit 104 may use a codebook subset. In such an embodiment, a 1 bit codebook subset restriction parameter s (e.g., subset indication) may be used to indicate different codebook subset selections. The value of s may depend on remote unit 102 TX port numbering and/or coherence (e.g., which pair of ports are coherent). Furthermore, in such an embodiment, the value of s may be sent from the remote unit 102 to the base unit 104 for a partial-coherent remote unit 102.

[0082] In certain embodiments, the subset restriction parameter may be either a capability indicator on which pairs of remote units 102 are coherent as part of remote unit 102 capability, or a codebook subset indicator. For either type of indicator, the setting of the value s by the remote unit 102, and the usage of s by the base unit 104 may be substantially the same.

[0083] In some embodiments, the first and second remote unit 102 TX ports may be coherent, and the third and fourth remote unit 102 TX ports may be coherent. In such embodiments, the value of s may be set to 0 to indicate such a coherency configuration. Moreover, a subset of codebook indexes 0-7 and 16-19 from Table 2, codebook indexes 0-7 from Table 3, and codebook indexes 0-3 from Table 4 may be used to calculate TPMI. In various embodiments, the TPMI-related signaling field in an uplink DCI may be allocated based on a number of valid codebook entries after applying the codebook subset selection to the uplink codebook. In such embodiments, such as with the value of s set to 0, 4 bits may be used for each single TPMI for rank 1, 3 bits may be used for each single TPMI for rank 2, and 2 bits may be used for each single TPMI for rank 3. In certain embodiments, the codebook index may equal TPMI in Table 2 with a TPMI less than 8 and the codebook index may equal TPMI+8 in Table 2 with a TPMI larger than 7 for PUSCH transmission. Moreover, in some embodiments, the codebook index may equal TPMI in Table 3 and Table 4 for PUSCH transmission.

[0084] In various embodiments, the first and third remote unit 102 TX ports may be coherent, and the second and fourth remote unit 102 TX ports may be coherent. In such embodiments, the value of s may be set to 1 to indicate such a coherency configuration. Moreover, a subset of codebook indexes 8-19 from Table 2, codebook indexes 8-15 in Table 3, and codebook indexes 4-7 in Table 4 may be used to calculate TPMI. In various embodiments, the TPMI-related signaling field in an uplink DCI may be allocated based on a number of valid codebook entries after applying the codebook subset selection to the uplink codebook. In such embodiments, such as with the value of s set to 1, 4 bits may be used for each TPMI for rank 1, 3 bits may be used for each TPMI for rank 2, and 2 bits may be used for each TPMI for rank 3. In

certain embodiments, the codebook index may equal TPMI+8 in Table 2 and Table 3, and the codebook index may equal TPMI+4 in Table 4 for PUSCH transmission.

[0085] In a further embodiment of partial-coherent transmission, SRS port number sequences may be predetermined (e.g., via specification, signaling, etc.). In such an embodiment, in response to 4 SRS ports being configured in one SRS resource with partial-coherent transmission capability, SRS port 0 and SRS port 1 may be coherent, and SRS port 2 and SRS port 3 may be coherent. Moreover, the base unit 104 may determine TPMI based on Table 10, Table 11, and Table 12.

[0086] In one embodiment, in response to a remote unit 102 only supporting non-coherent transmission, a base unit 104 may determine the TPMI based on Table 6, Table 7, Table 8, and Table 9 and may indicate the TPMI to the remote unit 102 for PUSCH transmission.

[0087] Figure 4 is a schematic flow chart diagram illustrating one embodiment of a method 400 for determining a TPMI for a codebook set. In some embodiments, the method 400 is performed by an apparatus, such as the base unit 104. In certain embodiments, the method 400 may be performed by a processor executing program code, for example, a microcontroller, a microprocessor, a CPU, a GPU, an auxiliary processing unit, a FPGA, or the like.

[0088] The method 400 may include receiving 402 information indicating a transmission capability of a remote unit. In certain embodiments, the method 400 includes determining 404 a transmit precoding matrix indication based on a rank and a codebook corresponding to the transmission capability and the rank, wherein the transmit precoding matrix indication corresponding to a rank of one includes a maximum of five bits, the transmit precoding matrix indication corresponding to a rank of two includes a maximum of four bits, and the transmit precoding matrix indication corresponding to a rank of three includes a maximum of three bits. In some embodiments, the method 400 includes transmitting 406 the transmit precoding matrix indication to the remote unit.

[0089] In one embodiment, the transmission capability is selected from the group including full-coherent transmission, partial-coherent transmission, and non-coherent transmission. In a further embodiment, the rank is selected from the group including a rank of one, a rank of two, a rank of three, and a rank of four.

[0090] In certain embodiments, the codebook corresponding to partial-coherent

transmission and a rank of one includes entries selected from the group including $\frac{1}{2} \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix}$

corresponding to a first index, $\frac{1}{2} \begin{bmatrix} 1 \\ -1 \\ 0 \\ 0 \end{bmatrix}$ corresponding to a second index, $\frac{1}{2} \begin{bmatrix} 1 \\ j \\ 0 \\ 0 \end{bmatrix}$ corresponding to a
