ABSTRACT OF THE DISCLOSURE

This interactive diagnostic system provides the automotive service professional with all the tools necessary to provide precision diagnostic testing on today's computer-controlled cars. This is accomplished by providing the system with means including an external computer for controlling operation of one or more specific actuators independent of the onboard computer and for simulating the operation of these latter sensors. At the same time, the electronic data entering and exiting the onboard computer including the actual data associated with the network of sensors and actuators can be continuously monitored and analyzed by the external computer.

2101336

-1-

INTERACTIVE DIAGNOSTIC SYSTEM FOR AN
AUTOMOTIVE VEHICLE, AND METHOD

5 The present invention relates generally to a diagnostic system for an automotive vehicle of the type having (1) a network of sensors and actuators for independently sensing and actuating a number of different functions within the vehicle and (2) an onboard computer for monitoring the sensors and controlling the operation of the actuators. The present invention relates more particularly to what may be referred to as an interactive system for diagnosing the performance of a vehicle (1) by controlling the operation of one or more of its specific actuators independent of its onboard computer, (2) by simulating the operation of one or more of its specific sensors independent of the actual operation of those sensors, and (3) by continuously monitoring and analyzing the other vehicle actuators and sensors and, in fact, all of the electronic data entering and/or exiting the onboard computer, preferably, in real time.

15 It is a fact that most new cars and trucks, that is, automotive vehicles generally, are far more sophisticated than their predecessors. As exemplified in Figure 1, a typical vehicle manufactured today, generally indicated at 8, includes an onboard computer 10 which is generally

-2-

referred to as an electronic control module. This ECM serves to control the operation of one or more specific actuators associated with the vehicle's auto drive system 12 including its engine and other components by responding to the network of corresponding sensors. Typical actuators which are usually solenoids, although not always, might include fuel injectors, an air diverter valve, an ignition module, valves associated with anti-lock brakes, as well as others, some of which are illustrated in Figure 1. Typical sensors may include temperature sensors, oxygen level sensors, sensors associated with anti-lock brakes and so on, some of which are also illustrated in Figure 1. The way in which these components interrelate with one another and with the electronic control module may be best exemplified by the way in which fuel injection is controlled as a function of oxygen levels within the engine. More specifically, the ECM uses an oxygen sensor in the exhaust manifold to sense the oxygen level there and, at the same time, it operates the fuel injector through an associated solenoid. Thus, if the ECM senses an increase in oxygen, it will automatically increase fuel consumption by appropriately operating the fuel injection solenoid and, if it senses a decrease in oxygen, it will automatically decrease fuel consumption by means of the same solenoid, thus achieving optimal emission levels.

Still referring to Figure 1, a typical arrangement 14 for electrically connecting the ECM 10 with its network of actuators and sensors 12 is illustrated. This connection arrangement includes an auto-side connector 16 having a series of auto-side plug-in terminals 18 respectively connected with associated sensors and actuators and a computer-side connector 20 disengageably connectable to the auto-side connector by means of corresponding, complementary computer-side plug-in terminals 22 connected to the

-3-

appropriate circuitry within electronic control module 10. In the embodiment illustrated in Figure 1, the auto-side terminals 18 are shown as the male terminals and the computer-side terminals 22 are shown as female terminals. For purposes of clarity, cooperating terminals 18, 22 are designated T1, T2, T3 and so on. Only ten such terminals have been illustrated for purposes of convenience but in today's vehicles, there can be as many as 100 such terminals. The components connected with these terminals vary between different vehicle makes and models. For example, the oxygen sensor might be associated with terminal T1 in one vehicle and T5 in another. Vehicle makes and models may include sensors and actuators that other vehicle makes and models do not have. For example, a knock sensor used to sense engine knocks, which result in the ECM retarding spark timing, is found generally only in more expensive cars.

Having described the present-day high tech automotive vehicle, attention is now directed to one prior art way in which it can be serviced. Specifically, the automotive service professional might use what is commonly referred to as a "breakout box", generally indicated by the reference numeral 24, for gaining access to all of the terminals T1-T10. To this end, the breakout box has its own adaptor 26 disposed between and connecting together auto-side connector 16 with computer-side connector 20 such that each terminal 18 remains connected to its associated terminal 22. At the same time, adaptor 26 is connected to the breakout box through a connecting harness 28 for electrically connecting the breakout box's own terminals 30 to corresponding terminals T1, T2, T3 and so on. In this way, the automotive service professional can easily gain access to any of the terminals T1 - T10 by means of terminals 30.

2101336

-4-

In actual practice, the breakout box 24 is typically used by the automotive service professional to diagnose a problem associated with energization of a trouble light on the dashboard of the vehicle in question. Many vehicle makes and models include their own trouble code associated with each given trouble light. Typically, a trouble code indicates some abnormal condition in a given circuit within the vehicle's electronic system. For example, trouble code 42 on a GM vehicle may indicate abnormal voltage readings from the oxygen sensor. Thus, on a vehicle with code 42 set, a professional may connect the breakout box 24 and insert a voltmeter into the terminal associated with the oxygen sensor on that particular vehicle, say terminal T⁵, and verify the actual voltage in the circuit. It is worthwhile noting that whereas some trouble codes are very specific, others are quite general and in many cases the same code will be set for many different problems; furthermore, many problems will cause the setting of multiple trouble codes.

It is important to note that the diagnostic system associated with the breakout box 24, as described above, is a passive system. That is, the automotive service professional uses the breakout box to access the connector terminals in order to observe the components associated with those terminals typically by connecting a volt meter and from those observations, he is hopefully able to diagnose the problem.

There are a number drawbacks associated with the passive diagnostic approach just described utilizing breakout box 24. One obvious drawback relates to the time it takes to make the diagnosis. An appropriate manual for each given vehicle make and model must be kept and reviewed in order to determine which terminals to access and what to look for,

-5-

depending upon the particular trouble light that is flashing and the particular vehicle. In many cases, the trouble that is described by the vehicle operator does not always result in a flashing trouble light or the trouble is intermittent and does not always occur at the time the vehicle is being diagnosed. After an extended diagnostic period, the problem may not be found or its results suspect. Moreover, the problem may only occur under certain conditions that cannot be duplicated at the service station. For example, evaluating problems associated with the air management system often require that the vehicle's engine be under load. Of course, this is not possible using breakout box 24 without actually driving the vehicle.

In view of the foregoing, the present invention generally seeks to provide a state-of-the-art diagnostic work station designed to provide automotive service professionals with all the tools necessary to perform precision diagnostic testing on today's computer-controlled engines, anti-lock brakes and other such components, as discussed previously in conjunction with Figure 1.

A more particular aspect of the present invention seeks to provide a diagnostic work station which utilizes its own external computer for continuously monitoring, preferably in real time, and analyzing electronic data entering and/or exiting the onboard computer of the vehicle being diagnosed including actual data associated with the vehicle's network of sensors and actuators.

Another particular aspect of the present invention seeks to provide a state-of-the-art diagnostic work station that takes an interactive role, which means that it is not only capable of analyzing the electronic data entering and/or exiting the onboard computer, but it is also capable of controlling the operation of one or more specific actuators independent of the onboard computer and simulating the operation of one or more specific sensors, independent of the actual operation of these sensors, as contrasted with the previously described breakout box 24 which merely takes a passive role.

-6-

Still another particular aspect of the present invention seeks to provide a state-of-the-art diagnostic work station that is rapidly and easily adapted for use with different vehicle makes and models.

In one broad aspect the invention pertains to a motor vehicle diagnosis apparatus for (1) coupling between technician-accessible electrical terminals of a motor vehicle connectable to on-vehicle sensors for responding to vehicle functions and providing vehicle function signals, on-vehicle actuators for receiving vehicle component control signals and controlling vehicle components, and an on-vehicle computer for receiving the vehicle function signals and providing the vehicle component control signals, and (2) monitoring selected communication channels between the on-vehicle computer, on-vehicle sensors and on-vehicle actuators. The apparatus comprises an external computer for receiving in real time vehicle function signals and vehicle component control signals entering and exiting the on-vehicle computer and a set of switching circuits for selectively establishing signal paths between the external computer and selected on-vehicle computer terminals for providing to the external computer selected vehicle function signals and selected vehicle component control signals entering and exiting the onboard computer.

As will be discussed in more detail hereinafter, the particular diagnostic work station, actually system, disclosed herein is specifically designed for high technology automotive vehicles of the type described in conjunction with Figure 1. Thus, it is designed for use with a vehicle including (1) a network of sensors and actuators for independently sensing and actuating a number of different functions within the vehicle, (2) an onboard computer for monitoring the sensors and controlling operation of the actuators, and (3) cooperating auto-side and computer-side connectors having cooperating auto-side and

-6A-

computer-side plug-in terminals for electrically connecting the onboard computer with the sensors and actuators, again as described previously in conjunction with Figure 1.

In accordance with one aspect of the present invention, the particular diagnostic work station disclosed herein utilizes means including its own computer arrangement separate from the vehicle's onboard computer, for continuously monitoring and analyzing in real time electronic data entering and/or exiting the onboard computer, that is, the ECM, including actual data associated with the vehicle's network of sensors and actuators. Thus, using the monitor

2101336

-7-

in association with the external computer arrangement, the outputs of a number of related sensors can be simultaneously observed visually while, at the same time, the operation of associated actuators are monitored.

5 In accordance with another, more complex aspect of the present invention, the diagnostic work station disclosed herein includes a series of components that cooperate with its external computer for allowing the work station to interact directly with the vehicle's network of sensors and
10 actuators and its onboard computer. This is accomplished first by providing suitable means for selectively and temporarily disconnecting one or more specific sensors and/or one or more specific actuators from the vehicle's onboard computer. At the same time, the work station's external
15 computer arrangement is temporarily connected with these latter sensors for simulating the action of each one independent of its actual operation and also connected to these latter actuators for controlling the operation of each of these actuators independent of the onboard computer.
20 At the same time, some of the other sensors and actuators, that is, those not disconnected from the vehicle's onboard computer, can be continuously monitored and analyzed by the external computer. Thus, if it is necessary to observe certain vehicle functions at high altitude or under high
25 or low temperature conditions, using the diagnostic work station disclosed herein, it is not necessary to move the vehicle to a location of high altitude or to subject the vehicle to high or low temperature conditions. Rather, all that is necessary is to disconnect the appropriate barometric
30 and temperature sensors from the vehicle's onboard computer and, using the external computer arrangement, simulate the way the sensors would operate at high altitude and at high or low temperature conditions so that the onboard computer thinks these latter conditions exist. The onboard computer

2101336

-8-

will then operate the rest of the vehicle functions as if that were the case and these latter functions can then be monitored and analyzed by the external computer under these simulated conditions.

5 Whether the diagnostic work station disclosed herein merely serves a passive role of continuously monitoring and analyzing the vehicle in question or actually interacts with the vehicle, as described briefly above, it is readily and rapidly adaptable for use with vehicles of different makes
10 and models. This is because, although different vehicle makes and models include different sensors and/or actuators and different onboard computers, the work station's external computer is provided with a database for distinguishing between these differences.

15 Other, more detailed features of the present invention will become apparent from the following detailed description in conjunction with the drawings, wherein:

FIGURE 1 diagrammatically illustrates, partially in block-diagram, a diagnostic system designed in accordance
20 with the prior art for use with high-technology automotive vehicles;

FIGURE 2 is a diagrammatic illustration, partially in block-diagram, of a diagnostic work station for similar high-technology vehicles, but one which is designed in accordance
25 with the present invention; and

FIGURE 3 is a diagrammatic illustration of a particular feature of the work station in Figure 2.

FIGURES 4 and 5 are further diagrammatic illustrations depicting the way the system functions.

2101336

-9-

Turning now to the drawings, attention is immediately directed to Figure 2, inasmuch as Figure 1 has been discussed previously. Figure 2 illustrates a diagnostic work station 32 which is designed in accordance with the present invention to provide automotive service professionals with all the tools necessary to perform precision diagnostic testing on today's high technology vehicles. One such vehicle, generally indicated by the reference numeral 34, is diagrammatically illustrated in Figure 2 and corresponds to the vehicle described heretofore in conjunction with Figure 1. Thus, vehicle 34 includes among other components, an entire auto-drive system 35 which itself includes an engine, transmission, brakes, and so on, as well as a network of sensors and actuators associated with these latter components. For purposes of convenience, the sensors and actuators are indicated by the letters S and A with numerical subscripts distinguishing one from the other. Vehicle 34 also includes an onboard computer, specifically the same electronic control module 10 and arrangement 14 for electrically connecting the ECM with the sensors and actuators as described in conjunction with Figure 1. It may be recalled that arrangement 14 includes an auto-side connector 16 having its own auto-side plug-in terminals 18 and a computer-side connector 20 including its own computer-side plug-in terminals 22. For purposes of convenience, only ten terminals are illustrated, specifically terminals T1-T10. Most of these terminals connect associated sensors or actuators with appropriate circuitry at ECM 10. For example, terminal T1 connects ECM 10 with sensor S1, terminal T2 connects the ECM to sensor S2, and so on. The particular components M7 and G8 illustrated as part of the auto-drive system and connected to the ECM through terminals T7 and T8 will be described hereinafter along with the function of terminal T9.

2101336

-10-

Having again described the necessary components of vehicle 34 for purposes of the present invention, attention is now directed to diagnostic work station 32. This work station includes its own external computer arrangement 36 which, as will be discussed in more detail below, is specifically designed for three primary purposes. First, it is designed to control the operation of one or more specific actuators independent of one another and independent of the onboard ECM 10. Second, it is designed to simulate the operation of one or more specific sensors, independent of one another and independent of their actual operation. Third, computer arrangement 36 is designed to continuously monitor and analyze in real time all of the electronic data entering and exiting ECM 10 including actual data associated with the network of sensors and actuators.

Still referring to Figure 2, work station 32 also includes an arrangement 38 which also serves a number of purposes. First, it serves to selectively and temporarily disconnect one or more specific sensors and/or actuators from ECM 10. Second, and at the same time, arrangement 38 serves to connect external computer arrangement 36 to those actuators that have been temporarily disconnected from ECM 10 so that the external computer arrangement can override the ECM and control those actuators. Third, arrangement 38 serves to connect the external computer arrangement 36 into the circuitry of ECM 10 associated with those sensors that have been temporarily disconnected in order to simulate the operation of those sensors. Fourth, arrangement 38 serves to connect external computer arrangement 36 to ECM 10 for monitoring the data entering and/or leaving the ECM, that is, the data passing between the ECM and various vehicle drive system components. Thus, as computer arrangement 36 operates a given actuator, for example, actuator A6, and simulates one or more sensors, for example, sensors S3 and

2101336

-11-

S4, it can also monitor the other actuators and sensors, that is, those actuators and sensors that remain connected to the ECM.

Having described work station 32 generally, attention is now directed to a number of particular examples of the way in which it may be used to diagnose problems associated with the vehicle 34. As one such example, it may be necessary to observe how the advance-retard angle associated with the vehicle's ignition timing changes with temperature. In this case, all of the drive system components in the vehicle remain connected to onboard ECM 10, except for a particular temperature sensor, for example sensor S4. This latter sensor is disconnected from its associated circuitry in ECM 10 and the associated circuitry is connected by arrangement 38 to external computer arrangement 36 through a cooperating computer-side terminal 22 via terminal T4, as will be seen. In this way, computer arrangement 36 can be operated to simulate the temperature sensor connected to T4 by generating the appropriate signal to ECM 10. By modulating this signal in the same way as the actual sensor S4 would, the ECM can be made to believe that the engine itself is varying in temperature causing it to vary the ignition timing accordingly. As a result, the vehicle's advance-retard angle can be observed as a function of temperature without ever leaving the service garage.

As another example, it may be necessary to test the performance of the vehicle's air management system. This system is supposed to allow a certain amount of air to flow from the exhaust back into the intake manifold for controlling the temperature in the manifold by using the heat from the exhaust air. This is controlled by a certain actuator, for example, the exhaust recirculation valve in General Motors cars. However, this valve will only open

-12-

under certain conditions. One such condition is when the vehicle is under load, as briefly mentioned earlier in the discussion of Figure 1. Thus, if the vehicle is at the garage, the vehicle's ECM will not itself open the exhaust recirculation valve since the vehicle itself is not under load. At the same time, it is not practical to actually drive the vehicle. Under these circumstances, work station 32 is especially appropriate. In this case, computer arrangement 36 takes over control of certain actuators and simulates certain sensors to make ECM 10 think that the vehicle is under a load. At the same time, it continuously monitors the valve in question in order to see if it actually does open the proper way under this load. Alternatively, it is also possible to use computer arrangement 36 to directly control the EGR valve, by disconnecting it from ECM 10, and driving it to open, simultaneously monitoring other vehicle conditions such as temperature and fuel modulation in order to discern whether the valve is operating properly.

The foregoing have been two examples of the way in which work station 32 is capable of taking an interactive role in diagnosing vehicle 34. The present invention is certainly not limited to those particular examples. In fact, in certain cases, work station 32 may be used solely for monitoring and analyzing certain vehicle functions without any interactive role at all. An example of this might be the vehicle's cruise control. Since the cruise control is not critical to the vehicle's operation, it may be desirable, from an economic standpoint, to provide the work station without means for interacting with the cruise control. In this case, the cruise control would be connected to computer arrangement 36 in a "monitor only" mode, in which case, the computer arrangement can still analyze operation of the cruise control and not directly affect its operation. In

-13-

a most economical version of work station 32, it would be designed only to continuously monitor and analyze in real time electronic data entering and exiting the ECM without any interactive roles at all. In this embodiment, the work station serves as a highly sophisticated analytical tool far superior to the breakout box illustrated in Figure 1, but would have less diagnostic capability than the interactive work station illustrated in Figure 2.

Having described the way in which work station 32 functions generally and having recited particular examples, attention is now directed to a more detailed discussion of computer arrangement 36 and connector arrangement 38. As illustrated in Figure 2, this latter arrangement including what may be referred to as a pod 40 which is comprised of a series of lines or channels C1, C2 and so on, include electronic switching circuits to be described below. This pod is disengageably connectable to a vehicle adaptor 42 by means of their respective plug-in cable harnesses 44 and 46. Adaptor 42 is comprised of its own auto-side connector 48 and its own computer-side connector 50, each of which includes its own plug-in terminals complementary to plug-in terminals 18 and 22. In this way the connectors 16 and 48 and the connectors 20 and 50 can be respectively connected together. The reason that the adaptor 42 is disengageably connectable with pod 40 by means of plug-in harnesses 44 and 46 is that the connectors 16 and 20 may differ for different vehicle makes and models and, hence, different adapters must be used. For example, in one vehicle make, the terminal T1 associated with the sensor S1, as shown in Figure 2, is connected to Channel C1. However, while not shown, for a different vehicle make, the terminal T1 may be associated with different drive system component, for example, sensor S4, and might therefore be connected through the cooperating adaptor to Channel C' for example. Thus,

-14-

each adapter has its own unique way of connecting terminals T1, T2 and so on with channel lines C1, C2 and so on.

As stated above, pod 40 is comprised of a series of electronic switching circuits which may be readily provided
5 by those with ordinary skill in the art. However, for purposes of simplicity, these switching circuits are depicted in Figure 2 as simple mechanical switches and will be referred to herein as either switches or switching circuits. It is important to note that there are three different sets
10 of switching circuits which perform three different functions. There is a first set of switching circuits generally represented by the switches S1, S2, S3 and so on. A second set is indicated at S'1, S'2 and so on, while a third set is shown at S"5, S"6, S"8 and S"10. The function
15 of each set will be described below.

Switches S1, S2, S3 and so on function to selectively connect or disconnect corresponding auto-side terminals 18 to or from associated computer-side terminals 22. Thus, the switch S1 on channel line C1 is shown in its
20 closed condition, thereby connecting the T1 terminal 18 to the T1 terminal 22. This in turn will electrically connect the sensor S1 to its associated circuitry in ECM 10 through the plug-in terminals T1. This is also true for switch S2 on channel line C2 which maintains sensor S2 connected to
25 ECM 10. On the other hand, sensors S3 and S4 are shown in an opened condition, thereby disconnecting the T3 and T4 terminals 18 from the T3 and T4 terminals 22 which, in turn, disconnect sensors S3 and S4 from ECM 10. Note that switches S6 is open, switches S5 and S10 are closed, and there are
30 no switches S associated with channel lines C7, C8 and C9. The C7 channel line, which is a monitor only line as described above, may be connected to, for example, the connector terminals associated with the vehicle's cruise

2101336

-15-

control. In this way, computer arrangement 36 can monitor and analyze the cruise control but it cannot interact with it. The C9 line in Figure 2 is actually provided to symbolically represent a series of lines for monitoring all
5 of the other lines. This is more realistically depicted in Figure 3, as will be seen. The C8 line will be discussed hereinafter.

The second series of switches, S'1, S'2 and so on, serve to connect corresponding computer-side terminals 22 to the
10 sensor simulating circuitry 56 within computer arrangement 36 while the third series of switches S"5, S"6 and S"8 serve to connect the corresponding auto-side terminals 18 to the actuator driving circuit 56 within computer arrangement 36. Thus, for example, switch S'1 is shown opened and therefore
15 assures that the circuitry within the ECM 10 and connected to the T1 computer-side terminal 22 is not driven by external computer arrangement 36. On the other hand, switching circuit S'3 connects computer arrangement 36 to the circuitry in ECM 10 associated with sensor S3 through the T3 computer-
20 side terminal 22. At the same time, switching circuit S"6 is closed and therefore connects actuator A6 with computer arrangement 36 through the T6 terminal 18.

With the possible exception of channel line C8, the status of the other switching circuits should be self
25 explanatory from Figure 2 and the discussion immediately above. Note specifically that the switching circuits S' are associated with sensors and thus connect the computer arrangement 36 to ECM 10 while the switching circuits S" are associated with actuators and hence connect computer
30 arrangement 36 to the actuators. With particular regard to line C⁸, it should be noted that it includes both an S' and an S" switching circuit. This is because the C⁸ line serves to test the ground lines in the entire vehicle system.

2101336

-16-

By closing the switch S'8, the ground lines in the ECM 10 can be resistance tested by injecting a known current into the line and measuring the resultant voltage. This is also true for the ground lines of the vehicle drive system side
5 by closing the switch S"8. While only one such line C8 is shown, there are usually a number of such lines.

Still referring to Figure 2, attention is now directed to a more detailed discussion of computer arrangement 36. As seen there, this arrangement includes its own CPU 52 which
10 can be, for example, part of a readily providable personal computer including an associated monitor 54 and keyboard 55. The arrangement also provides a suitable and readily providable interface between the computer including the necessary digital/analog converters one of which is generally
15 indicated at 56 and analog/digital converters generally indicated at 58. Note that the digital/analog converters 56 allow CPU 52 to drive (actually control the operation of) particular vehicle actuators through switching circuits S" and simulate particular sensors feeding into circuitry
20 within the ECM 10 through cooperating switching circuits S'. On the other hand, the analog/digital converters allow the external CPU 52 to "listen to", that is, monitor data entering and leaving ECM 10. In the case of this listening function, one or more A/D converters can be used for
25 listening to all the terminal lines utilizing a suitable and readily providable sweep mechanism which is operated in a time slicing mode. Also, as will be seen hereinafter in conjunction with Figure 3, some of the D/A converters associated with actuators are actually driver circuits
30 including on-off switches. Further, note that channels C1 - C10 in pod 40 connect to A/D circuitry 58 through a conventional and readily providable multiplexer 59 forming part of the sweep mechanism just mentioned so that individual

2101336

-17-

terminal lines and specific groups of terminal lines can be scanned by the CPU.

As indicated above, CPU 52 may be part of any suitable and readily providable computer, for example a standard personal computer. The software used to run the computer, represented generally by the diagrammatically depicted look up table 59 or menu, is also readily providable by those with ordinary skill in the art in view of the teachings herein. The software must be designed to control the various actuators in the intended manner and simulate the various sensors. It also must have the ability to analyze the various data presented to the external computer. A particular feature of work station 32 resides in a specific software database maintained within CPU 52. As indicated above, different vehicle makes and/or models compatible with work station 32 may include different sensors or actuators, different onboard computers and/or a different arrangement of auto-side and computer-side terminals. As a result, external CPU 52 includes a database for distinguishing between any of these differences in different vehicle makes and models. Thus, the automotive service professional can easily enter the appropriate vehicle identification into CPU 52 using keyboard 55 and provide the appropriate adaptor 32 in order to make the work station compatible with the particular vehicle in question. To this end, the database also includes performance information pertaining to specific sensors and actuators for particular vehicle makes and models. In addition, the CPU and its software include suitable and readily providable means for storing electronic data presented to it into memory, a database having exemplary data associated with the networks of sensors and actuators, and means for comparing the actual data stored in memory with the exemplary data. The CPU and its software also include suitable and readily providable means for carrying

2101336

-18-

out different diagnostic tests by operating certain specific actuators and simulating certain specific sensors in a predetermined way.

Software menu 60 is shown specifically including an
5 "AUTO SELECT" item which represents a data base for distinguishing between vehicle makes and models. The T1 - T10 items represent data associated with the sensors, actuators and other components connected with connector terminals T1 - T10. As stated above, this data varies with
10 the particular vehicle selected and would include for certain components the desired performance criteria to be used as a reference against actual performance data. The items labeled "Test No. 1", "Test No. 2" and so on refer to a data base for carrying out different predetermined diagnostic
15 tests. The menu 60 illustrated in Figure 2 is by no means complete, nor is it intended to be complete. It is provided rather as an example of the necessary software required to operate CPU 52 in the desired manner, which software is readily providable, as indicated above. A more detailed
20 discussion of the way in which the overall work station operates from a software standpoint will follow.

Turning now to Figure 3, attention is directed to a more accurate representation of the switching circuits within pod 40. In this case, the terminal lines associated with
25 terminals T1 and T2 are shown as monitoring lines and, hence, include no switching circuits at all. On the other hand, the terminal lines associated with terminals T3, T4 and T5 do include switching circuits. Note specifically that a single switching circuit is used to combine the function
30 of the previously described switches S and S' or S". Thus, for example, in the case of terminal T3, a single switching circuit S"3 is used to connect the auto-side and ECM side terminals T3 to one another and alternatively to connect

2101336

-19-

the ECM side terminal T3 to D/A circuitry within computer arrangement 36. This is also the case for switching circuit S⁴. On the other hand, the terminal line T5 includes a switching circuit Sw5 which in one position connects together the ECM side and auto-side terminals T5 and in the opposite position connects computer arrangement 36, actually its driver circuit 56, to the auto-side terminal T5 for connection with the associated actuator A5. As indicated previously, some if not all of the actuators are controlled through driver circuits including on/off switches rather than through D/A converters. In this way, it is insured that any given actuator is always driven by the external computer in a way which is consistent with the actuator's electrical properties, i.e., voltage, current, impedance, etc. For example, a solenoid requires different drive parameters than a stepper motor. Note also that not only the monitoring lines T1 and T2 in Figure 3 are shown including A/D converters but all of the other lines, that is, those including switching circuits also include A/D converters which serve to monitor or listen to those lines, regardless of the position of any given switching circuit. In this latter regard, in actual practice, it may be desirable to include a single A/D converter for listening purposes along with a sweep mechanism operated in a time slice mode.

Having now described overall workstation 32, attention is now directed to a specific example of the way in which it operates from a software standpoint. This example is not intended to limit the present invention. The discussion to follow will be organized by means of headings in association with Figures 4-5, starting with a discussion of the Data Base Structure, and followed by examples of various predetermined tests which the system is capable of performing.

2101336

-20-

1. DATA BASE STRUCTURE (see Figure 4)

The data base (DB) is composed of various tables as shown in Figure 4, as follows:

Component Table: For every component used with any vehicle, there is an entry in this table. Every entry contains the component identification (ID), type (sensor, thermistor, solenoid, etc.) and electrical parameters (min-max volts, resistance, inductance, translation tables to physical units, etc.).

Channel Table: For every channel C1, C2 and so on in the pod there is an entry in this table. Every entry contains the channel mux-address, the switch address, the D/A address, and other electrical parameters (i.e. gain, impedance, drive capabilities, etc.).

2. CONNECTOR TABLE: For every ECM used in any vehicle, there is an entry in this table describing the vehicle connector 14 (see Figure 1). Every entry is itself a table with an entry for every terminal on the particular ECM. Every terminal entry contains the terminal name (e.g., T1, T2), the component connected to this terminal, and the channel C1, C2, and so on, through which this terminal is routed in pod 40.

Engine Table: For every engine used in any vehicle there is an entry in this table containing the vehicle ID number (VIN), general engine information (i.e., number of cylinders, ignition type, injection type, etc.) and the ID of the connector for this engine.

The following specific information should be noted for exemplary purposes.

2101336

-21-

1. Many engines may share the same connector.
2. Many connectors may have the same terminal configuration.
3. Different components may connect to same terminal on different connectors.
4. Some channels may connect to different components on different connectors.

3. TEST FLOW

Having described the contents of information in the DB, we now proceed with examples of how this information is used in conjunction with actual testing of a vehicle. The first example will be what is called a sweep test, invoked by say item Test No. 1 in menu 60 of Fig. 2. The sweep test is a software function that examines all terminals of a given vehicle sequentially, monitoring them under known conditions for abnormal behavior.

The second example to be discussed, is a functional bypass test, invoked say by item Test No. 5 of menu 60, Fig. 2. A functional test will look at a group of terminals simultaneously, examining a particular correlation in their operation.

4. SWEEP TEST INFORMATION FLOW

Sweep tests are divided into functional groups: key off, key on-engine off, cranking and engine running tests.

Key Off Tests: These tests look at all power ground lines. A software function scans the connector table for the vehicle (Fig. 4) searching for those terminals connected to a component of the type "POWER" or "GROUND", as contained in the component information pointed at through the connector table. For every power terminal, the voltage is read from

2101336

-22-

the appropriate channel and compared to the nominal values of the matching component in the DB.

For every ground terminal, voltage is read and compared as above, then the appropriate switch S" is turned on, routing that channel to one of the D/A's. The particular D/A is then driven by software to inject a known current into the line connected to the terminal on the car side. Voltage drop is read from the appropriate channel and line resistance is computed and compared to the DB values.

- 10 Key on-Engine Off : These tests look at all sensors and actuators. For every sensor, voltage is read from the appropriate channel and compared to DB values as above. For all solenoids (actuators) voltage and resistance are measured as for ground lines. In addition, when current is injected into a solenoid, the actual current taken by the solenoid is plotted against time, and inductance is computed from this curve, and compared to DB values.

5. BYPASS TEST INFORMATION FLOW

As an example, consider the oxygen sensor bypass test.

- 20 Background: Under constant running conditions (RPM and load) the vehicle ECM will constantly monitor the oxygen sensor output which may be high, indicating high oxygen contents in the exhaust manifold, or low, indicating low oxygen. The ECM responds by modulating the fuel injectors to counter the oxygen readings. Thus, when oxygen is high, the ECM will widen the injector pulse width, causing more fuel to be delivered into the combustion chamber, eventually reducing the oxygen contents in the exhaust manifold, and vice versa when oxygen is low. This scheme is called a negative feedback loop, where injector pulse width is the controlled variable and oxygen is the error signal.

-23-

Test Description: While the engine is running, the system 32 will inject a simulated oxygen signal into the ECM. The signal is a square wave, with min-max voltage range based on DB values for a given oxygen sensor. While injecting 5 this signal, the system will simultaneously monitor the Injector driver line, computing in real time the variation in injector pulse width, and also the output of the real oxygen sensor.

Expected Result: The correlation between the injected signal 10 and fuel modulation indicates whether or not the ECM is properly responding to variations in oxygen. The skew between the injected oxygen and the real oxygen indicates the time response of the oxygen sensor. For a vehicle without any faults, the schematic results are shown in Figure 15 5.

6. TEST FLOW FOR OXYGEN BYPASS

A software function is provided within the system to execute the above test. First, the connector table for the vehicle (Figure 4) is scanned, searching for the terminals 20 corresponding to the oxygen signal, the injector drivers (one or more) and the tach signal (RPM). The oxygen channel switch is configured for bypass into the ECM. The appropriate D/A is configured to generate a square wave with min-max voltage equal to nominal values for oxygen from the 25 DB. The injector driver, the oxygen sensor and the tach signal are configured for "Read" (to listen) by properly selecting their respective channels in the A/D mux. The user is instructed to rev the engine to 2000 RPM, and the test begins:

30 The system monitors the tach signal, waiting for 2000 RPM. At that point, the D/A is enabled which causes the

2101336

-24-

simulated signal to be generated. The program then monitors simultaneously the simulated value, the real oxygen value and the injector driver. The injector signal is converted in real time to a pulse-width value, and is plotted against
5 time together with the other values. This goes on for approximately 15 seconds, at which time bypass is disabled and monitoring stops. The final stage is a mathematical computation done on the data recorded in memory. The correlation of simulated oxygen and injector pulse width
10 is computed, and the skew between simulated oxygen and real oxygen is measured. Both values are compared against good known results.

It is to be understood that the present invention is not limited to the particular computer arrangement 36 or
15 the particular connector arrangement 38 illustrated in Figures 2 and 3. Rather, based on the teachings herein, one with ordinary skill in the art can readily modify either of these arrangements so long as they fulfill the functions herein. Moreover, based on the teachings herein, and with
20 suitable and readily providable knowledge about particular automotive vehicles, one with ordinary skill in the software art can readily design the software used to operate computer 52. The present invention does not relate to the software per se but rather to the way in which the overall diagnostic
25 station is able to continuously monitor and analyze vehicle 34 and more particularly to the way it is able to take an interactive role in the diagnostic process. In an actual working embodiment, an IBM PC AT or compatible system has been provided. Tables 1-3 forming the Appendix I (pages
30 A1-A20) attached hereto list examples of actual engines, specific functions and tests by the actual embodiment. The present invention contemplates but is not limited to these particular engines, functions and tests.

/*      TABLE - 2 : LIST OF ALL SENSORS, ACTUATORS AND SIGNALS      */
/*      CURRENTLY IN THE DATABASE FOR GM AND FORD.                    */
/*      NOTE : A PARTICULAR VEHICLE WILL ONLY USE A SUBSET OF THE    */
/*      COMPONENTS IN THIS LIST, TYPICALLY 20-40.                    */
/*****

```

LEGEND :

MAKE : MANUFACTURER ID.

10 GM - GENERAL MOTORS (ALL DIVISIONS).
FORD - FORD MOTOR CO. (ALL DIVISIONS).

NAME : A SHORTHAND NAME USED BY THE MANUFACTURER TO DESIGNATE THE PARTICULAR SIGNAL.

TYPE : THE COMPONENT TYPE CONNECTED TO THIS SIGNAL.

	RELAY	- MECHANICAL ON/OFF RELAY.
15	SWITCH	- ELECTRICAL ON/OFF SWITCH.
	SOLENOID	- ELECTRICAL SOLENOID.
	STP_MOTOR	- STEPPER MOTOR.
	WARN_LT	- WARNING LIGHT.
	THERMISTOR	- HEAT VARIABLE RESISTOR.
20	RESISTOR	- VARIABLE RESISTOR (POTENTIOMETER).
	TRANSDUCER	- SOLID STATE SENSOR.
	PIEZO	- PIEZO ELECTRIC TRANSDUCER
	FREQ_GEN	- FREQUENCY GENERATOR.
	HALL_SWITCH	- HALL EFFECT SWITCH.
25	POWER	- POWER LINE.
	GROUND	- GROUND LINE.

DIRECTION :

INPUT - TO ECM, GENERALLY A SENSOR.
OUTPUT - FROM ECM, GENERALLY AN ACTUATOR.

	MAKE	NAME	TYPE	DIRECTION	DESCRIPTION

KEY OFF ENG OFF TESTS:

- 1) TEST VOLTAGE AT CONTINUOUS BATTERY PINS.
- 2) TEST RESISTANCE OF POWER GROUNDS.
- 3) TEST RESISTANCE OF THE IDLE AIR CONTROL STEPPER MOTOR.
- 4) TEST RESISTANCE OF THE IDLE SPEED CONTROL DC REVERSIBLE MOTOR.

KEY ON ENG OFF TEST:

- 10 1) TEST VOLTAGE AT KEY POWER PINS.
- 2) TEST VOLTAGE AT SYSTEM GROUND PINS.
- 3) TEST VOLTAGE AT SENSOR GROUND PINS.
- 4) TEST VOLTAGE AT VREF PINS.
- 5) TEST VOLTAGE OF TPS.
- 15 6) TEST VOLTAGE AIR TEMPERATURE SENSOR.
- 7) TEST VOLTAGE OF BARO SENSOR.
- 8) TEST VOLTAGE OF MANIFOLD AIR PRESSURE SENSOR.
- 9) TEST VOLTAGE OF MANIFOLD AIR FLOW SENSORE.
- 10) TEST VOLTAGE OF COOLANT TEMP SENSOR.
- 20 11) TEST VOLTAGE OF ALL SOLENOIDS.
- 12) TEST RESISTANCE OF ALL SOLENOIDS.
- 13) TEST VOLTAGE OF ALL INJECTORS.
- 14) TEST RESISTANCE OF ALL INJECTORS.

CRANKING TEST:

- 25 1) TEST RPM DURING CRANKING.
- 2) TEST FUEL PUMP OPERATION DURING CRANKING.
- 3) TEST MANIFOLD AIR PRESSURE DURING CRANKING.
- 4) TEST MANIFOLD AIR FLOW DURING CRANKING.
- 5) TEST CYLINDER ID SIGNAL DURING CRANKING.
- 30 6) TEST VOLTAGE DROP IN CONTINUOUS BATTERY PINS AFTER CRANKING.
- 6) TEST VOLTAGE DROP IN KEY POWER PINS AFTER CRANKING.

-44-

WHAT IS CLAIMED IS:

1. For use in a diagnostic system for an automotive vehicle of the type having (i) network sensors and actuators for independently sensing and actuating a number of different functions within the vehicle (ii) an onboard computer for monitoring said sensors and controlling the operation of said actuators, and (iii) means for electrically connecting said onboard computer with said sensors and actuators, said connecting means including an auto-side connector having a series of auto-side plug-in terminals respectively connected with individual ones of said sensors and actuators and a computer-side connector disengageably connectable to said auto-side connector and having corresponding complementary computer-side plug-in terminals connected to appropriate circuitry within the onboard computer, an arrangement for temporarily disconnecting a selected one or a combination of said auto-side terminals from corresponding computer-side terminals, whereby to temporarily disconnect a selected one or combination of specific sensors and/or actuators from said outboard computer, said arrangement comprising:

(a) a plurality of electronic switching circuits including a first network of such circuits individually connected between individual auto-side and computer-side terminals and a second network of such circuits connectable between an external computer arrangement and either individual auto-side or computer-side terminals, each of said switching circuits being designed to operate between a closed condition and an open condition for connecting and disconnecting its associated auto-side and computer-side terminals to and from one another and for connecting and disconnecting the external computer arrangement to an associated auto-side or computer-side terminal, said networks of circuits being designed for use with a particular make and/or model of said automotive vehicle in which its auto-side and computer-side are terminals connected with particular sensors and actuators in accordance with a specific connection scheme which differs from a different make and/or model vehicle.

-45-

2. An interactive diagnostic system for an automotive vehicle of the type having (i) a network of sensors and actuators for independently sensing and actuating a number of different functions within the vehicle, (ii) an onboard computer for monitoring said sensors and controlling the operation of said actuators, and (iii) means for electrically connecting said onboard computer with said sensors and actuators, said connecting means including an auto-side connector having a series of auto-side plug-in terminals respectively connected with individual ones of said sensors and actuators and a computer-side connector disengageably connectable to said auto-side connector and having corresponding, complementary computer-side plug-in terminals connected to appropriate circuitry within the onboard computer, said diagnostic system comprising:

(a) first means for temporarily disconnecting a selected one or combination of said auto-side terminals from corresponding computer-side terminals, whereby to temporarily disconnect a selected one or combination of specific sensors and/or actuators from said onboard computer, said first means including a network of switching circuits individually connected between auto-side and computer-side terminals, each of said switching circuits being designed to operate independent of but simultaneously with the other circuits in any selected combination between a closed condition and an open condition for connecting and disconnecting its associated auto-side and computer-side terminals to and from one another;

(b) second means temporarily connectable with said one or combination of auto-side terminals when the latter are disconnected from their corresponding computer-side terminals for controlling the operation of said one or combination of specific actuators of said onboard computer; and

(c) third means temporarily connectable with said one or combination of computer-side terminals when the latter are disconnected from their corresponding auto-side terminals for simulating the operation of said one or combination of specific sensors independent of the actual operation of these latter sensors.

-46-

3. A system according to claim 2 wherein said second means includes an external computer arrangement separate from said onboard computer for controlling the operation of said one or combination of specific actuators independent of said onboard computer by generating specific information digitally, converting said digital information to analog signals and directing said analog signals to said one or combination of specific actuators through said one or combination of auto-side terminals.

4. A system according to claim 3 wherein said third means includes said external computer arrangement separate from said onboard computer for simulating the operation of said one or combination of specific sensors independent of the actual operation of these latter sensors by generating specific signals digitally from said external computer, converting said digital signals to analog information and directing said analog information to the appropriate circuitry within said onboard computer through said one or combination of computer-side terminals.

5. A system according to claim 4 wherein said network of switching circuits are electronic switching circuits and wherein each of said second and third means includes a network of electronic switching circuits individually connected between said external computer arrangement and individual auto-side or computer-side terminals, each of said switching circuits being designed to operate between a closed condition and an open condition for connecting and disconnecting the external computer arrangement to its associated auto-side or computer-side terminals.

6. A system according to claim 5 wherein the first mentioned network of switches forming part of said first means also serves as the network of switches forming part of said second and third means.

7. A system according to claim 5 wherein said computer arrangement includes means for operating said networks of electronic switching circuits individually or in selected combinations.

-47-

8. A system according to claim 4 wherein different vehicle makes and/or models compatible with said system may include different sensors and/or actuators, a different onboard computer and/or a different arrangement of auto-side and computer-side terminals, and wherein said external computer arrangement includes a data base for distinguishing between any of said differences in different vehicle makes and models.

9. A system according to claim 8 wherein said external computer arrangement includes a visual display for visually displaying information from said external computer arrangement.

10. A system according to claim 9 wherein said external computer arrangement includes a database for appropriately scaling visually displayed graphic data depending on the vehicle being diagnosed, and the electrical parameters of the sensor/actuator connected to the terminal pin or pins being acted upon.

11. A system according to claim 8 wherein said database includes performance information pertaining to specific sensors and actuators for particular vehicle makes and models.

12. A system according to claim 2 including means for continually monitoring in real time electronic data entering and/or exiting said onboard computer including actual data associated with said network of sensors and actuators.

13. A system according to claim 12 wherein said monitoring means includes an external computer arrangement separate from said onboard computer for analyzing said electronic data.

14. A system according to claim 13 wherein said computer includes means for storing said electronic data into memory, a data base having exemplary data associated with said network of sensors and actuators, and means for comparing the actual data stored in memory with said exemplary data.

15. A system according to claim 12 including an external computer arrangement separate from said onboard computer forming part of said second means, third means, and said monitoring means for

(a) controlling the operation of said one or more specific actuators independent of said onboard computer,

-48-

(b) simulating the operation of said one or more specific sensors independent of the actual operation of the latter sensors, and/or

(c) analyzing said electronic data.

16. A system according to claim 15 wherein said external computer arrangement includes means for causing said second, third, and monitoring means to automatically operate in a predetermined way to carry out different predetermined tests on said network of sensors and actuators.

17. A diagnostic system for an automotive vehicle of the type having (i) a network of sensors and actuators for independently sensing and actuating a number of different functions within the vehicle (ii) an onboard computer for monitoring said sensors and controlling the operation of said actuators, and (iii) means for electrically connecting said onboard computer with said sensors and actuators, said connecting means including an auto-side connector having a series of auto-side plug-in terminals respectively connected with individual ones of said sensors and actuators and a computer-side connector disengageably connectable to said auto-side connector and having corresponding, complementary computer-side plug-in terminals connected to appropriate circuitry within the onboard computer, said diagnostic system comprising:

(a) monitoring means also including a network of individual circuits disengageably connectable with and between said auto-side and computer-side terminals for independently and substantially simultaneously monitoring in real time individual electronic data entering and exiting said onboard computer through said individual circuits, the individual data being associated with the individual sensors and actuators making up said network of sensors and actuators, said monitoring means also includes an external computer arrangement separate from said onboard computer for analyzing said electronic data.

18. A system according to claim 17 wherein said computer arrangement includes means for storing said electronic data into memory, a database having exemplary data associated with said

-49-

network of sensors and actuators, and means for comparing the actual data stored in memory with said exemplary data.

19. A system according to claim 17 wherein different vehicle makes and/or models compatible with said system may include different sensors and/or actuators, different onboard computers and/or different arrangements of auto-side and computer-side terminals, and wherein said external computer arrangement includes a database for distinguishing between any of said differences in different vehicle makes and/or models.

20. The system according to claim 19 wherein said database includes performance information pertaining to specific sensors and actuators for particular vehicle makes and models.

21. The system according to claim 20 including:

(a) first means for selectively and temporarily disconnecting one or more of said auto-side terminals from corresponding computer-side terminals, whereby to selectively and temporarily disconnect one or more specific sensors and/or actuators from said onboard computer;

(b) second means temporarily connectable with said one or more specific auto-side terminals when the latter are disconnected from their corresponding computer-side for controlling the operation of said one or more actuators independent of said onboard computer; and

(c) third means temporarily connectable with said one or more specific computer-side terminals when the latter are disconnected from their corresponding auto-side terminals for simulating the operation of said one or more specific sensors independent of the actual operation of these latter sensors.

22. A system according to claim 21 wherein said external computer arrangement forms part of said second and third means for controlling the operation of said one or more specific actuators independent of said onboard computer and for simulating the operation of said one or more specific sensors independent of the actual operation of these latter sensors.

-50-

23. A system according to claim 17 wherein said network of individual circuits is designed for use with a particular make and/or model of said automotive vehicle in which its auto-side and computer-side terminals are connected with particular sensors and actuators in accordance with a specific connection scheme which differs from a different make and/or model vehicle.

24. A system according to claim 23 wherein said monitoring means includes a second network of individual circuits disengageably connectable with and between said auto-side and computer-side terminals, said second network corresponding in function to said first mentioned network of circuits but specifically for said different and/or model vehicle.

25. A method of diagnosing for an automotive vehicle of the type having (i) a network of sensors and actuators for independently sensing and actuating a number of different functions within the vehicle (ii) an onboard computer for monitoring said sensors and controlling the operation of said actuators, and (iii) means for electrically connecting said onboard computer with said sensors and actuators, said connecting means including an auto-side connector having a series of auto-side plug-in terminals respectively connected with individual ones of said sensors and actuators and a computer-side connector disengageably connectable to said auto-side connector and having corresponding, complementary computer-side plug-in terminals connected to appropriate circuitry within the onboard computer, said method comprising the steps of:

(a) using an arrangement of independently actuatable switches disengageably connected with said auto-side and computer-side terminals, (i) temporarily and simultaneously disconnecting selected ones of said auto-side terminals from corresponding computer-side terminals arrangement, and (ii) connecting elected ones of the disconnected auto-side terminals to an external computer arrangement, and (iii) connecting selected others of the disconnected computer-side terminals to said computer arrangement in order to selectively and temporarily disconnect one or more specific sensors and/or actuators from said onboard computer, and

-51-

(b) through said arrangement of switches, controlling the operation of said one or more specific disconnected actuators by said external computer arrangement through the selected, disconnected auto-side terminals, independent of said onboard computer and/or simulating operation of said one or more specific disconnected sensors by said external computer arrangement through the selected disconnected computer-side terminals, independent of the actual operation of those sensors.

26. A method according to claim 25 including the step of continuously monitoring in real time electronic data entering and/or exiting said onboard computer including actual data associated with said network of sensors and actuators through said arrangement of switches.

27. A method according to claim 26 wherein said external computer arrangement is used to control the operation of said specific actuators, to simulate the operation of specific sensors, and to analyze the electronic data entering and/or exiting said onboard computer continuously monitored through said arrangement of switches.

28. A method according to claim 27 wherein different vehicle makes and/or models compatible with said method may include different sensors and/or actuators, different onboard computers and/or a different arrangement of auto-side and computer-side terminals, said method including the steps of providing a database in said external computer for distinguishing between any of said differences in said vehicle makes and/or models and for providing a different arrangement of switches for different vehicle makes and/or models.

29. A method according to claim 28 including the step of providing said external computer with a database including performance information pertaining to specific sensors and actuators for particular vehicle makes and/or models.

30. A diagnostic system for an automotive vehicle of the type having (i) a network of sensors and actuators for independently sensing and actuating a number of different

-52-

functions with the vehicle (ii) an onboard computer for monitoring said sensors and controlling the operation of said actuators, and (iii) means for electrically connecting said onboard computer with said sensors and actuators, said connecting means including an auto-side connector having a series of auto-side plug-in terminals respectively connected with individual ones of said sensors and actuators and a computer-side connector disengageably connectable to said auto-side connector and having corresponding, complementary computer-side plug-in terminals, connected to appropriate circuitry within the onboard computer, said diagnostic system comprising:

(a) controlling, simulating and monitoring means for (i) controlling the operation of one or a combination of said actuators independent of said onboard computer, (ii) for simulating the operation of one or a combination of said sensors independent of the actual operation of the latter sensors, and/or (iii) for continuously monitoring in real time electronic data entering and exiting said onboard computer, which data is associated with one, all or selectable combinations of said network of sensors and actuators, said controlling, simulating and monitoring means also including an external computer arrangement separate from said onboard computer for analyzing said electronic data.

31. A system according to claim 30 wherein said network of sensors and actuators is designed for use with a particular make and/or model of said automotive vehicle in which its auto-side and computer-side terminals are connected with particular sensors and actuators in accordance with a specific connection scheme which differs from a different make and/or model vehicle.

32. A system according to claim 31 wherein said monitoring means includes a second network of individual circuits disengageably connectable with and between said auto-side and computer-side said terminals, said second network corresponding in function to said first mentioned network of circuits but specifically for said different make and/or model vehicle.

-53-

33. A motor vehicle diagnosis apparatus for coupling between (1) technician-accessible electrical terminals of a motor vehicle connectable to an on-vehicle computer, on-vehicle sensors for responding to vehicle functions and on-vehicle actuators for controlling vehicle components and (2) electrical terminals coupled to an external computer, the apparatus comprising:

a first set of switching circuits for establishing first electrical connections selectively between designated on-vehicle computer terminals and designated terminals of said on-vehicle sensors and on-vehicle actuators;

a second set of switching circuits for establishing second electrical connections selectively between the external computer terminals and designated on-vehicle computer terminals;

a third set of switching circuits for establishing electrical connections between said external computer terminals and designated on-vehicle sensor terminals and on-vehicle actuator terminals; and

wherein said first, second and third sets of switching circuits are controllable for carrying simulated sensor signals from the external computer to the on-vehicle computer, for carrying simulated actuator signals from the external computer to the on-vehicle actuators, and for carrying signals from said on-board computer to said external computer.

34. The apparatus of claim 33 wherein said second set of switching circuits is integral with a first group of said first set of switching circuits and said third set of switching circuits is integral with a second group of said first set of switching circuits, distinct from said first group.

35. The apparatus of claim 33 wherein said external computer further comprises:

a driver circuit comprised of a plurality of on/off switches and D/A converters for selectively providing simulated actuator signals to selected on-vehicle actuator terminals and simulated sensor signals to selected on-vehicle computer terminals;

at least one analog-to-digital converter for receiving signals from selected on-vehicle computer terminals; and

-54-

a central processing unit operating under the control of software for controlling said driver circuit.

36. A motor vehicle diagnosis apparatus for (1) coupling between technician-accessible electrical terminals of a motor vehicle connectable to on-vehicle sensors for responding to vehicle functions and providing vehicle function signals, on-vehicle actuators for receiving vehicle component control signals and controlling vehicle components, and an on-vehicle computer for receiving the vehicle function signals and providing the vehicle component control signals, and (2) monitoring selected communication channels between the on-vehicle computer, on-vehicle sensors and on-vehicle actuators, said apparatus comprising:

an external computer for receiving in real time vehicle function signals and vehicle component control signals entering and exiting said on-vehicle computer; and

a set of switching circuits for selectively establishing signal paths between said external computer and selected on-vehicle computer terminals for providing to said external computer selected vehicle function signals and selected vehicle component control signals entering and exiting said onboard computer.
