ABSTRACT

The present invention provides novel heat stable polyamide-imide polymers having excellent flow properties which render them more readily processible into fibers, films, sheets and other molded articles. The polymers are prepared by forming the polycondensation product of one or more aromatic diamines and one or more trifunctional acid anhydride monomers, at least one of said diamine monomers containing the group

\[
\text{CF}_3 - C - R
\]

linking two aromatic moieties, wherein R is CF₃ or phenyl. In addition to improved flow properties, the polyamide-imide polymers of this invention also exhibit improved solubility properties in most organic solvents, improved resistance to attack by chlorinated solvents such as trichloroethylene as compared with polyimides, improved hydrophobic properties as well as excellent thermal properties including resistance to thermooxidative degradation.

POLYAMIDE-IMIDE POLYMERS HAVING FLUORINE-CONTAINING LINKING GROUPS

This application is related to copending application Ser. Nos. 316,254, 316,342, and 316,220, all filed on even date herewith.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to aromatic polyamide-imide polymers containing the hexafluorosilanepropyli- dene or the 1-phenyl-2,2,2-trifluoroethane linking group having improved physical and chemical properties, and to a method for preparing such polymers.

2. Description of Related Art

Polyamide-imide polymers and copolymers are known in the art. These materials are generally prepared by the condensation polymerization of trifunctional amide monomers such as the 4-acid chloride of trimellitic anhydride and one or more aromatic diamines. Examples of such polyamide-imide polymers are disclosed in U.S. Pat. Nos. 3,347,828, 3,494,890, 3,661,832 and 3,920,612.

These polymers may be characterized by extremely good high temperature properties (Tg of about 275°C or higher), good high temperature stability, good tensile strength at high temperatures, good mechanical properties and good chemical resistance. These polyamide-imides are useful as wire enamels, coatings, laminates, molded products, films, fibers, impregnating varnishes and in other applications where high thermal stability is required.

One of the problems associated with such polymers is that they exhibit generally poor flow properties which render them difficult to process, particularly to injection mold or to spin into fibers. These polymers are also relatively hydrophilic and tend to absorb moisture which can affect their clarity, heat stability, processability, mechanical and electrical properties.

Attempts have been made in the art to improve the flow properties of polyamide-imide polymers. For example, U.S. Pat. No. 4,448,925 discloses including from about 1 to about 10 percent phthalic anhydride into the polymerization recipe to provide polyamide-imide copolymers having improved flow properties. However, this technique for improving flow properties is made at the expense of the heat stability and chemical resistance of the polymer. Yet another method for improving the flow properties of such polymers is to form blends thereof with up to about 10% by weight of a polyamide such as nylon 6 or nylon 66, as disclosed in U.S. Pat. No. 4,575,924. Once again however, such an approach to solving the flow problem is made at the expense of the thermal stability and optical clarity of the resultant polymer blend.

SUMMARY OF THE INVENTION

The present invention provides novel heat stable polyamide-imide polymers having excellent flow properties which render them more readily processible into fibers, films, sheets and other molded articles. The polymers are prepared by forming the polycondensation product of one or more aromatic mono-acid/anhydride monomers with one or more aromatic diamine monomers, at least one of said aromatic diamine monomers containing the groups

\[
\text{CF}_3 - \text{C} - \text{R}
\]

linking two aromatic moieties, wherein \( R \) is \( \text{CF}_3 \) or phenyl. In addition to improved flow properties, the polyamide-imide polymers of this invention also exhibit improved solubility properties in most organic solvents, improved resistance to attack by chlorinated solvents such as trichloroethylene as compared with polyimides, improved hydrophobic properties as well as excellent thermal properties, including resistance to thermooxidative degradation.

DETAILED DESCRIPTION OF THE INVENTION

The polyamide-imide polymers of the present invention may be characterized as having structural units of the formula:

\[
(\text{O}) - \text{C} - \text{V} - \text{Na} - \text{A} - \text{HN} - \text{C} - \text{A} - \text{O} - \text{O} - \text{C} - \text{V} - \text{B} - \text{HN} - \text{C} - \text{B} - \text{O} - \text{O}
\]

wherein the terms (a) and (b) are equal to the mole fraction of each recurring unit in the polymer chain and (a) ranges from about 0.0 to about 0.95, (b) ranges from 1.00 to about 0.05, with the proviso that the sum of (a) and (b) is equal to 1.00, \( n \) is a number sufficient to give rise to a polyamide-imide inherent viscosity of at least about 0.05 as measured from a solution of the polymer in dimethyl acetamide at 25°C. At a polymer concentration of 0.5 weight percent, \( A \) is a divalent aromatic moiety, and \( B \) is a divalent, aromatic moiety of the residuum formula:

\[
\text{(2)}
\]

wherein \( x \) is a non-interfering monovalent substituent selected from the group consisting of hydrogen, chloro, fluoro, lower alkyl or alkoxy having 1 to 6 carbon atoms, hydroxy and phenyl.

In the more preferred embodiment of this invention, the preferred minimum inherent viscosity of the poly-
mer is at least about 0.1 dl/g. Also, where the (a) segment of the polymer is present, (a) may range from about 0.05 to about 0.95 and (b) ranges from about 0.05 to about 0.95.

With respect to the polyamide-imides of formula 1, B may be the divalent residuum a 3F or 6F-Diamine, including one of the following: 2,2-bis(3-aminophenyl) hexafluoropropane; 2,2-bis(4-aminophenyl) hexafluoropropane; 2-(3-aminophenyl)-2-(4-aminophenyl) hexafluoropropane; 2,2-bis(3-amino-4-methylphenyl) hexafluoropropane; or the -1-phenyl-2,2,2-trifluoroethane counterparts thereof.

In the polyamide-imides of formula 1, A is the divalent residuum of one or a combination of aromatic diamines having the formula:

$$\text{NH}_{2}-R-\text{NH}_{2}$$  \(\text{(3)}\)

wherein R is the aromatic moiety of a phenylene, naphthalene, bis or polyphenylene type compound. R is preferably selected from:

![Diagram]

wherein \(R'\) is a divalent moiety independently selected from a covalent carbon to carbon bond, methylene, ethylene, propylene, isopropylene, hexafluoroisopropylidene, 1-phenyl-2,2,2-trifluoroethylidene, dichloro and difluoroalkylones up to 3 carbons, oxy, thio, sulfnyl, sulfonyl, sulfonylamido, carbonyl, oxydi- carbonyl, oxydimethylene, sulfonfdioxyl, carbonyldioxyl, disilanylene, polyisilanylene up to 8 Si atoms disiloxanylene, and a polysiloxanylene up to 8 Si atoms. Preferably, the linking group R, is selected from oxy, hexafluoroisopropylidene, 1-phenyl-2,2,2,2-trifluoroethylidene, carbonyl, methylene, a covalent carbon to carbon bond, disiloxanylene and polysiloxanylenes. Most preferably, \(R'\) is a carbon to carbon bond, methylene, hexafluoroisopropylidene, 1-phenyl-2,2,2,2-trifluoroethylidene and oxy.

The hydrogen atoms of the aromatic groups A and/or B may be substituted by one or more non-interfering monovalent substituents such as chloro, fluoro, lower alkyl or alkoxy having up to 6 carbon atoms, hydroxy and phenyl. Also, the term “aromatic” as used herein is meant to include heteroaromatics wherein one or more of the ring atoms is replaced with —O—, —S— or —N— atoms.

Polymers of Formula 1 above where (a) is zero are prepared by forming the polymer condensation product of A 3,4, or 5-trimellitic acid anhydride monomer or amide-forming derivative thereof with an aromatic diamine monomer containing the hexafluoroisopropylidene or 1-phenyl-2,2,2-trifluoroethane linking groups as set forth in Formula 2 above. Polymers of Formula 1 above where (a) is more than zero are prepared by also including in the aforementioned polymer condensation reaction an aromatic diamine monomer having the formula 3.

Divalent diamine monomers of Formula 3 which may be used in preparing the polyamide-imide copolymers of the present invention include:

- m-phenylene diamine;
- p-phenylene diamine;
- 1,3-bis(4-aminophenyl) propane;
- 2,2-bis(4-aminophenyl) propane;
- 4,4’-diamino-diphenyl methane;
- 1,2-bis(4-aminophenyl) ethane;
- 1,1-bis(4-aminophenyl) ethane;
- 2,2’-diamino-diethyl sulfide;
- bis(4-aminophenyl) sulfide;
- 2,4’-diamino-diphenyl sulfide;
- bis(3-aminophenyl)sulfone;
- bis(4-aminophenyl) sulfone;
- 4,4’-diamino-dibenzyl sulfoxide;
- bis(4-aminophenyl) ether;
- bis(3-aminophenyl) ether;
- bis(4-aminophenyl) diethyl silane;
- bis(4-aminophenyl) diphenyl silane;
- bis(4-aminophenyl) ethyl phosphine oxide;
- bis(4-aminophenyl) phenyl phosphine oxide;
- bis(4-aminophenyl)-N-phenylamine;
- bis(4-aminophenyl)-N-methylamine;
- 1,2-diamino-naphthalene;
- 1,4-diamino-naphthalene;
- 1,3-diamino-naphthalene;
- 1,6-diamino-naphthalene;
- 1,7-diamino-naphthalene;
- 1,8-diamino-naphthalene;
- 2,3-diamino-naphthalene;
- 2,6-diamino-naphthalene;
- 1,4-diamino-2-methyl-naphthalene;
- 1,5-diamino-2-methyl-naphthalene;
- 1,3-diamino-2-phenyl-naphthalene;
- 4,4’-diamino-biphenyl;
- 3,3’-diamino-biphenyl;
- 3,3’-dichloro-4,4’-diamino-biphenyl;
- 3,3’-dimethyl-4,4’-diamino-biphenyl;
- 3,4’-diamino-4,4’-biphenyl;
- 3,3’-dimethoxy-4,4’-diamino-biphenyl;
- 4,4’-bis(4-aminophenoxyl)-biphenyl;
- 2,4-diamino-toluene;
- 2,5-diamino-toluene;
- 2,6-diamino-toluene;
- 3,5-diamino-toluene;
- 1,3-diamino-2,5-dichloro-benzene;
- 1,4-diamino-2,5-dichloro-benzene;
- 1-methoxy-2,4-diamino-benzene;
- 1,4-diamino-2-methoxy-5-methyl-benzene;
- 1,4-diamino-2,3,5,6-tetramethyl-benzene;
- 1,4-bis(2-methyl-4-aminopyridyl)-benzene;
- 1,4-bis(1,1-dimethyl-5-aminopyridyl)-benzene;
- 1,4-bis(4-aminophenoxyl)-benzene;
- o-xylene diamine;
- m-xylene diamine;
- p-xylene diamine;
- 3,3’-diamino-benzophenone;
- 4,4’-diamino-benzophenone;
- 2,6-diamino-pyridine;
- 3,5-diamino-pyridine;
- 1,3-diamino-adamantane;
- 3,3’-diamino-1,1,1’-diadamantane;
- N-(3-aminophenyl)-4-aminobenzamide;
- 4-aminophenyl-3-aminobenzoxoate;
- 2,2-bis(4-aminophenyl) hexafluoropropane;
4,954,610

2,2-bis(3-aminophenyl) hexafluoropropane;
2-(3-aminophenyl)-2-(4-aminophenyl) hexafluoropropane;
2,2-bis(4-(3-aminophenoxynaphthalenyl))hexafluoropropane;
2,2-bis(4-(2-chloro-3-aminophenyl))hexafluoropropane;
1,1-bis(4-aminophenyl)-1-phenyl-2,2,2-trifluoroethane;
1,1-bis(4-(3-aminophenoxynaphthalenyl))-1-phenyl-2,2,2-trifluoroethane;
1,4-bis(3-aminophenyl)buta-1,4-ene-3-yne;
1,3-bis(3-aminophenyl) hexafluoropropane;
1,5-bis(3-aminophenyl) decafluoropentane; and mixtures thereof.

It is to be pointed out that also within the scope of Formula 1 are polymers wherein both of the A moiety and the B moiety are based on diaryl diamines having a fluorne-containing linking group. In such instances the two diamines employed are different, such as a polymer prepared by the condensation of an aromatic monoacid anhydride with a mixture of 2,2-bis(3-aminophenyl) hexafluoropropane and 2,2-bis(4-aminophenyl) hexafluoropropane.

In the preferred embodiments of the present invention, polyamide-imides of Formula 1 above are prepared by forming the polymer condensation product of a mixture of a monoacid anhydride such as 4-trimellitoyl anhydride chloride (4-TMAC) having the structure:

![Structure of 4-TMAC](image)

with a mixture of an aromatic diamine having the structure of Formula 3 above and a 2,2-bis(aminophenyl) hexafluoropropane monomer (6F-Diamine) having the structure:

![Structure of 6F-Diamine](image)

wherein X is a non-interfering monovalent substituent selected from the group consisting of hydrogen, chloro, fluoro, lower alkyl or alkoxyl having 1 to 6 carbon atoms, hydroxy and phenyl. Suitable such diamines include 2,2-bis(3-aminophenyl) hexafluoropropane, 2,2-bis(4-aminophenyl) hexafluoropropane and 2(3-aminophenyl)-2-(4-aminophenyl) hexafluoropropane.

As indicated above, the polyamide-imide polymers of this invention may be made 100 mole % on fluorne-containing amino monomers. More preferably, however, the polymers contain from about 1 to about 75 mole percent of fluorne containing amino monomers and most preferably from about 2 to about 50 mole percent of fluorne containing amino monomers, based on the total weight of amino monomers present in the polymer.

The acid/anhydride, and diamine reactants, particularly those containing fluorne, are preferably substantially electronically pure and are referred to as electronic grade monomers. They generally should be at least about 98.5% pure, and more preferably at least about 99.5% pure.

The polyamide-imides of the present invention are preferably prepared by a solution polymerization process, i.e., by reacting the acid anhydride, diacid anhydride and diamine monomers in an appropriate solvent, optionally in the presence of a catalyst or an added inorganic salt such as lithium chloride or calcium chloride, and in a nitrogen atmosphere. Polymerization is conducted under anhydrous, isothermal polymerization conditions and preferably at a temperature of less than 35°C. The intermediate polyamide-polyamic acid reaction product is then cyclized to form the polyamide-imide either by chemical dehydration or by an appropriate heat treatment. The polymer may be recovered by precipitation in water or an alcohol such as methanol, and washed.

The solvents useful in the solution polymerization process for synthesizing the polyamide-imide compositions are the organic solvents whose functional groups do not react with the reactants to any appreciable extent. In addition to being inert to the system, and preferably, being a solvent for the polyamide-imide, the organic solvent must be a solvent for at least one of the reactants, preferably for all of the reactants. The normally liquid organic solvents of the NN,N-dialkyloxycarbonyl-ylamide class are useful as solvents in the process. The preferred solvents are the lower molecular weight members of this class, particularly N,N-dimethylformamide and N,N-dimethylacetamide. Other useful solvents are N,N-diethyformamide, N,N-diethylacetamide, N,N-dimethylmethoxycetamide, N-methyl caprolactam, and the like. Other solvents which may be used include dimethylsulfoxide, N-methyl-2-pyrrolidone, tetramethyl urea, pyridine, dimethyl sulfoxide, hexamethylophosphoramide, tetramethylene sulfone, formamide, N-methylformamide, butyro lactone and phenols such as m-cresol. The solvents can be used alone or in combinations.

To obtain the maximum inherent viscosity, i.e., maximum degree of polymerization, for any particular combination of monomers, solvent, etc., and thus produce shaped articles such as films and filaments of optimum toughness, it has been found that the temperature throughout the reaction should be maintained below 50°C, preferably below about 35°C.

The degree of polymerization of the polyamide-imides is subject to deliberate control. The use of equimolar amounts of the reactants under the prescribed conditions provides polyamide-imides of very high molecular weight. The use of either reactant in large excess limits the extent of polymerization. In addition to using an excess of one reactant to limit the molecular weight of the polyamide-imides, a chain terminating agent such as phthalic anhydride may be added to the reactants to limit the extent of polymerization.

In the preparation of the polyamide-imides, it is desired that the molecular weight be such that the inherent viscosity of the polymer is at least about 0.1, more preferably from about 0.2 to about 1.0. The inherent viscosity is measured at 25°C at a concentration of 0.5% by weight of the polymer in a suitable solvent such as dimethylacetamide.

The quantity of organic solvent used in the process need only be sufficient to dissolve enough of one reactant, preferably the diamine, to initiate the reaction of
the diamine and the other monomers. It has been found that the most successful results are obtained when the solvent represents at least 60% of the final solution, that is, the solution should contain 0.05-40% of the polymeric component, more preferably 15 to 25%.

The second step of the process (dehydration) is performed by treating the polyamide-polyamic acid with a dehydrating agent alone or in combination with a tertiary amine such as acetic anhydride or an acetic anhydride-pyridine mixture. The ratio of acetic anhydride to pyridine can vary from just above zero to infinite mixtures.

Tertiary amines having approximately the same activity as the preferred pyridine can be used in the process. These include isoquinoline, 3,4-lutidine, 3,5-lutidine, 4-methyl pyridine, 3-methyl pyridine, 4-isopropyl pyridine, N,N-dimethyl benzyl amine, 4-benzyl pyridine, and N,N-dimethyl dodecyl amine. These amines are generally used from 0.3 to equimolar amounts with that of the anhydride converting agent. Trimethylamine and triethylene diamines are much more reactive, and therefore are generally used in still smaller amounts. On the other hand, the following operable amines are less reactive than pyridine: 2-ethylpyrididine, 2-methyl pyridine, triethyl amine, N-ethyl morpholine, N,N-dimethyl cyclohexylamine, 4-benzoxyl pyridine, 2,4-lutidine, 2,6-lutidine and 2,4,6-collidine, and are generally used in larger amounts.

An alternative method for the preparation of the polyamide-imides is the thermal dehydration of the intermediate polyamide-polyamic acid. This transformation is generally performed in bulk, preferably in the form of a shaped article, e.g., film or filament of the polyamic acid. The dehydration is conducted stepwise starting at temperatures of about 100° C. and increasing the temperature progressively to about 300° C. or even higher, depending on the particular case, towards the end of the imidization step. The reaction is preferably performed under an inert atmosphere, and atmospheric or reduced pressures can be employed.

The polyamide-imides of the present invention generally have a weight average molecular weight (Mw) within the range of from about 5,000 to about 200,000 or more.

The following examples are illustrative of the invention:

EXAMPLE 1

This example details the preparation of a polyamide-imide having the structure of Formula 1 above wherein (a) is zero and based on the reaction product of 0.10 moles of 4-trimellityl anhydride chloride (4-TMAC) and 0.10 moles of 2,2-bis (4-aminophenyl) hexafluoropropane (4,4'-6F Diamine).

A 1000 ml 4 neck flask, fitted with a stirrer, condenser, Y tube, powder addition funnel, thermometer, dry ice-acetone cooling bath and nitrogen blanket was charged under nitrogen atmosphere with 33.4 grams (0.10 moles) of 4,4'-6F Diamine along with 400 grams of reagent grade dimethyl acetamide (DMAC). The mixture was stirred to dissolve the 4,4'-6F Diamine and cooled down to a temperature of about -10° C. About 10.5 grams of 4-TMAC was gradually added to this solution over a period of about 20 minutes while continuing agitation and maintaining a temperature of about -5° C. under nitrogen atmosphere. An additional 10.5 grams of 4-TMAC was then gradually added over about 46 minutes time while continuing agitation at about -5° C. under nitrogen atmosphere. The beaker containing the 4-TMAC was rinsed with 46 grams of additional DMAC and this was also added to the polymerization solution. The temperature of the solution was allowed to rise to 5° C. and 11.2 grams (0.11 mole) of triethylamine was charged dropwise over about 18 minutes time under nitrogen atmosphere while continuing agitation. Thereafter, 46 grams of DMAC was charged under nitrogen and the reaction mass was agitated at a temperature of 15° C. for three hours. Thereafter, 38.0 grams of pyridine and 54.2 grams of acetic anhydride was charged under nitrogen atmosphere and the reaction mass was then allowed to agitate for about 12 hours at room temperature to complete cyclization. The reaction mass was filtered to remove pyridine hydrochloride. The polymer formed above was precipitated from solution in methanol by the addition of methanol to the reaction liquor, that is by reverse precipitation, using about 2000 ml of methanol for every 500 grams of polymeric solution. The resulting polymer was then washed with water and methanol, and chopped to a fine powder as an aqueous suspension in a mechanical blender. The powder was dried overnight in a vacuum oven at 65° C.

This polymer has the structural formula:

```
EXAMPLE 2

This example sets forth the preparation of a polyamide-imide having the structure of Formula 1 above wherein (a) is zero based on the reaction product of 0.00736 moles of 4-TMAC and 0.00736 moles of 2,2-bis(3-aminophenyl) hexafluoropropane (3,3'-6F Diamine).

This polymer has the structural formula:

The procedure of Example 1 was repeated but the following materials and quantities were employed:

*Not tested.

The flow properties of the polyamide-imides of this invention, the control of Example 6, and a commercially available polyamide-imide sold by Amoco under its Trade Name Torlon® 4203L may be compared by forming compression molded discs of each polymer type. Discs of approximately 1 inch diameter were prepared using a hot press and piston mold to form the molded discs. Approximately 1/8 inch of polymer in powdered form was sprinkled into the bottom of a mold piston and the piston was inserted between the pallets of a hot press and heated to 300 °C. After coming to temperature, a pressure of 2000 psi was applied to the piston for 3 minutes. The pressure was then released, the mold cooled and the molded polymer disc having a thickness of about 20 mil was removed from the mold. Each of the polymers of Examples 1–5 produced a clear, transparent, white to yellow disc having good flexural properties. The control disc of Example 6 was a non-transparent, compressed, fused yellow powder which was sintered in nature, indicative of poor flow and poor molding properties. The disc made from TORLON was in the form of compressed, fused yellow green pellets.

The polyamide-imides of the present invention may be used in their preimidized form (polyamide-polyamic acid) as solutions in organic solvent to produce films, coatings, composites and the like which may be cured in-situ to form the polyamide-imide by the application of heat.

The polyamide-imides may be molded using techniques such as compression molding or injection molding to produce melt fabricated articles such as fibers, films, safety masks, windshields, electronic circuit substrates, airplane windows or the like. They may be compounded with graphite, graphite fiber, molybdenum disulfide or PTFE for the production of self-lubricating wear surfaces useful for piston rings, valve seats, bearings and seals. They may also be compounded with fibers such as glass, graphite or boron fibers to produce molding compounds for high strength structural components such as jet engine components. The polyamide-imides may also be compounded with fric-
tion materials to produce molding compounds for high temperature braking components or with abrasive materials such as diamonds for high speed grinding wheels.

The polyamide-imides may be cast as films useful as wire and cable wraps, motor slot liners or flexible printed circuit substrates. They may be used as coatings on substrates such as aluminum or silicone dioxide. They are also useful to produce high temperature coatings for magnetic wire, dip coatings for various electronic components, protective coatings over glass, metal and plastic substrates, wear coatings, and photo-resist coatings useful in microelectronic processing.

The polyamide-imides may also be used to produce high temperature adhesives for bonding aerospace structures or electrical circuitry, conductive adhesives when mixed with conductive fillers such as silver or gold for microelectronic applications, or adhesives for glass, metal or plastic substrates.

The polyamide-imides may also be used as varnish compositions or matrix resins to produce composites and laminates. The varnish compositions and matrix resins may be used to impregnate glass or quartz cloth, or graphite or boron fibers, for the production of radomes, printed circuit boards, radiological waste containers, turbine blades, aerospace structural components or other structural components requiring high temperature performance, non-flammability and excellent electrical properties.

In general, the polyamide-imides and polyamidic-acid precursors of this invention may be used in all applications as disclosed in copending application Ser. No. 124,704, filed in the U.S. Patent and Trademark Office on Nov. 24, 1987, the disclosure of which application is incorporated herein by reference.

It is to be understood that the above described embodiments of the invention are illustrative only and that modifications throughout may occur to those skilled in the art. Accordingly, this invention is not to be regarded as limited to the embodiments disclosed herein, but is to be limited as defined by the appended claims.

What is claimed is:

1. A polyamide-imide polymer containing at least one recurring structural unit of the formula:

wherein the terms (a) and (b) are equal to the mole fraction of each recurring unit in the polymer chain and (a) ranges from about 0.0 to about 0.95, (b) ranges from about 1.00 to about 0.05, with the proviso that the sum of (a) and (b) is equal to 1.00, n is a number sufficient to give rise to a polyamide-imide inherent viscosity of at least about 0.05 as measured from a solution of the polymer in dimethylacetamide at 25° C. at a polymer concentration of 0.5 weight percent;

A is a divalent aromatic moiety, and B is a divalent aromatic moiety containing the ring substituted or ring unsubstituted residuum selected from:

wherein x is a non-interfering monovalent substituent selected from the group consisting of hydrogen, chloro, fluoro, lower alkyl or haloxy having 1 to 6 carbon atoms, hydroxy and phenyl.

2. The polymer of claim 1 wherein B is the aromatic residuum of diamine selected from the group consisting of 2,2-bis (3-aminophenyl) hexafluoropropane, 2,2-bis (4-aminophenyl) hexafluoropropane, 2-(3-aminophenyl) -2-(4-aminophenyl) hexafluoropropane, 2,2-bis (3-amino-4-methylphenyl) hexafluoropropane; or the -1-phenyl-2,2,2-trifluorocethane counterparts thereof.

3. The polymer of claim 2 wherein (a) is zero.

4. The polymer of claim 3 wherein the inherent viscosity is at least 0.1 dl/g.

5. The polymer of claim 2 wherein (a) ranges from about 0.05 to about 0.95 and (b) ranges from about 0.95 to about 0.05.

6. The polymer of claim 5 wherein A is the aromatic residuum of a diaryl diamine having the formula:

wherein R' is a divalent moiety independently selected from a covalent carbon to carbon bond, methylene, ethylene, propylene, isopropylene, hexafluoroisopropylidene, 1-phenyl-2,2,2-trifluoroethyldiene, dichloro and difluoroalkynes up to 3 carbons, oxy, thio, sulfanyl, sulfonyl, sulfonamido, carboxyl, oxycarbonyl, oxydimethylene, sulfonilidoxy, carboxyldioxy, disilanylene, polysilanylene up to 8 Si atoms; disiloxanylene, and a polysiloxanylene up to 8 Si atoms.

7. The polymer of claim 6 wherein R' is

8. The polymer of claim 6 wherein R' is methyl.

9. The polymer of claim 6 wherein R' is oxygen.
10. The polymers of claims 1 or 5 containing from about 1 to about 100 mole percent of fluorine-containing monomers.

11. The polymers of claim 10 containing from about 2 to about 50 mole percent of fluorine-containing monomers.

12. A shaped article comprising the polymer of claim 1.

13. The shaped article of claim 12 produced by a compression molding process.
UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 4,954,610
DATED : Sept. 4, 1991
INVENTOR(S) : Paul N. Chen, and Rohitkumar H. Vora

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:
