FLOW LOCK GATHERING OF PACKET DATA

FIELD OF THE INVENTION

One embodiment of the invention relates to communications and computer systems, especially routers, packet switching systems, and other devices; and more particularly, one
5 embodiment relates to using ordered locking mechanisms to maintain sequences of items which may include converting between ordered locking mechanisms, especially for maintaining requisite packet orderings when distributing packets to be processed to different packet processing engines.

BACKGROUND OF THE INVENTION

10 The communications industry is rapidly changing to adjust to emerging technologies and ever increasing customer demand. This customer demand for new applications and increased performance of existing applications is driving communications network and system providers to employ networks and systems having greater speed and capacity (e.g., greater bandwidth). In trying to achieve these goals, a common approach
15 taken by many communications providers is to use packet switching technology. Increasingly, public and private communications networks are being built and expanded using various packet technologies, such as Internet Protocol (IP). Note, nothing described or referenced in this document is admitted as prior art unless explicitly so stated.

A network device, such as a switch or router, typically receives, processes, and
20 forwards or discards a packet based on one or more criteria, including the type of protocol used by the packet, addresses of the packet (e.g., source, destination, group), and type or quality of service requested. Additionally, one or more security operations are typically performed on each packet. But before these operations can be performed, a packet classification operation must typically be performed on the packet.

25 These operations consume time and resources, so one way to speed up their performance is to use multiple processors and to process packets in parallel. However, certain packets belonging to a stream of packets may need to be forwarded from the packet processors or even processed in the order received. Moreover, maintaining the original sequence of packets is in conflict with the desire to retire packets from a processor as soon
30 as they are done in order to clear resources to process more packets. Desired is a way of preserving only the critical order of flows, such as, but not limited to that which does not impose arbitrary and non-optimal order between unrelated packets.

SUMMARY OF THE INVENTION

Disclosed are, *inter alia*, methods, apparatus, data structures, computer-readable medium, and mechanisms for using ordered locking mechanisms to maintain sequences of items which may include converting between ordered locking mechanisms. These items
5 may correspond to anything, including, but not limited to packets, data items, processes, threads, etc. However, using ordered locks to maintain sequences of packets, especially for maintaining requisite packet orderings when distributing packets to be processed to different packet processing engines, may be particularly useful.

The number of locks employed by an embodiment may vary and typically is
10 commiserate with the needs of the application. Locks can be used to maintain strong ordering of a stream of items. Additionally, locks can be used to induce ordering of items. For example, a lock can be converted to multiple different locks which allows the same order to be maintained within the different locks, while allowing the items of the different locks to be processed in any order, such as, but not limited to being processed in parallel.
15 Similarly, multiple locks can be converted to a single lock which induces ordering among items previously in the different locks (e.g., typically with the ordering being that in which locking requests are processed).

Additionally, certain embodiments may provide for the locking mechanism to perform atomic operations, which are inherent or explicitly associated with a locking item.
20 Examples of such atomic actions include, but are not limited to conversion of locks, sequence number generation and/or checking, memory operations, data manipulation operations, etc. In one embodiment, a set or command queue of instructions or other indications corresponding to the atomic operations to be performed are associated with a locking item. By allowing the locking mechanism to perform or cause to be performed
25 these operations, the critical latency can typically be reduced as these operations typically can be pipelined and localized, rather than distributed. For example, in one embodiment, such an operation is performed by the locking mechanism or a processing element associated with the locking mechanism, and thus, the delay of the communication between the locking mechanism and the lock requestor before the operation is performed is typically
30 reduced or eliminated.

One embodiment identifies a particular item, and in response, generates a locking request to an ordered lock. The ordered lock is configured to maintain a locking queue of

identifiers corresponding to locking requests in the order requested. One or more instructions are associated with the particular identifier, and when the particular identifier reaches the head of the locking queue, the one or more instructions are performed.

One embodiment repeatedly identifies a particular packet, and in response,
5 generates a locking request to an ordered lock, wherein the ordered lock maintains a locking queue of identifiers corresponding the locking requests in the order requested. Acceptances requests corresponding to packets are communicated to the ordered lock. The ordered lock repeatedly removes a particular identifier from the head of the locking queue, and grants a locking acceptance request corresponding to the particular identifier if a
10 corresponding acceptance request was previously generated, or waits until the locking acceptance request corresponding to the particular identifier is generated and then granting the locking acceptance request corresponding to the particular identifier.

One embodiment processes packets by distributing packets to packet processing engines while maintaining order of streams of packets using ordered locks. In response to
15 a particular packet processing engine completing processing of a particular packet, a gather instruction is attached to the particular identifier of a particular ordered lock associated with the particular packet and the packet processing engine is released to be able to process another packet or perform another function. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, with the gather
20 instruction causing the processed particular packet to be sent. The releasing of the packet processing engine is performed prior to performing the gather instruction. In one embodiment, performing the gather instruction includes communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet.

One embodiment receives a particular packet of a stream of packets. The packet is
25 stored in a packet data storage and a packet handle data structure identifying the packet in the packet data storage is allocated. The particular packet is associated with a particular identifier of a particular ordered lock of one or more ordered locks. The particular packet is distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular
30 packet, a gather instruction is attached to the particular identifier and the packet processing engine is released to be able to process another packet or perform another function. The gather instruction is performed in response to the particular ordered lock being acquired by

the particular identifier, with performing the gather instruction including communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet. The gather mechanism receives a copy of the packet handle data structure, which is released after the gather mechanism receives the copy of the packet handle data structure.

5 The releasing of the packet processing engine is performed prior to performing the gather instruction, and releasing the packet handle data structure is performed prior to the sending of the processed packet. In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of one or more ordered locks associated with the stream of packets to the particular ordered lock
10 associated with the sub-stream.

One embodiment receives a particular packet of a stream of packets. The packet is stored in a packet data storage and a packet handle data structure identifying the packet in the packet data storage is allocated. The particular packet is associated with a particular identifier of a particular ordered lock of one or more ordered locks. The particular packet is
15 distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular packet, a gather instruction is attached to the particular identifier. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, with performing the gather instruction including communicating a gather request
20 to a gather mechanism, wherein the gather mechanism prepares and sends the processed particular packet. The gather mechanism receives a copy of the packet handle data structure, and then the packet handle data structure is reused by the particular packet processing engine to perform further processing in response to the processing of the particular packet. The reusing of the packet handle data structure is commenced prior to the
25 sending of the processed packet. In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of said one or more ordered locks associated with the stream of packets to the particular ordered lock associated with the sub-stream. In one embodiment, the further processing includes generating and sending a new packet.

30 One embodiment receives a particular packet of a stream of packets. The packet is stored in a packet data storage and a packet handle data structure identifying the packet in the packet data storage is allocated. The particular packet is associated with a particular

identifier of a particular ordered lock of one or more ordered locks. The particular packet is distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular packet, a gather instruction is attached to the particular identifier. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, which includes communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet and then notifies the particular packet processing engine. In response to this notification, the particular packet is further processed by the particular packet processing engine.

In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of said one or more ordered locks associated with the stream of packets to the particular ordered lock associated with the sub-stream. In one embodiment, the further processing includes sending information contained in the particular packet to a different destination than that specified in the particular packet.

One embodiment includes multiple packet processing engines, an ordered lock manager and a distributor. The ordered lock manager is configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released. The distributor is configured to receive a packet, make a locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing engine of the packet processing engines. The particular processing engine is configured to communicate one or more instructions corresponding to the packet to the ordered lock manager after completing processing of the packet, and after communication of said one or more instructions, the particular packet processing engine is released so that it can process another packet.

In one embodiment, the ordered lock manager is configured to notify the distributor in response to receiving the set of instructions, and the distributor is configured to release the packet processing engine in response to said notification. In one embodiment, the one or more instructions includes a gather instruction for the packet. One embodiment includes a gather mechanism, wherein the ordered lock manager is configured to communicate a

gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier.

One embodiment includes multiple packet processing engines, an ordered lock manager, a distributor, and a gather mechanism. The ordered lock manager configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released. The distributor is configured to receive a packet, make a locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing engine of the packet processing engines, wherein the particular processing engine is configured to communicate one or more instructions corresponding to the packet to the ordered lock manager after completing processing of the packet, wherein said one or more instructions includes a gather instruction for the packet.

The ordered lock manager is configured to communicate a gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier, wherein the gather mechanism prepares and sends the processed particular packet and then notifies the particular packet processing engine. The particular packet processing engine is configured to further process the packet in response to receiving said notification. In one embodiment, the further processing includes sending information contained in the packet to a different destination than that specified in the packet.

BRIEF DESCRIPTION OF THE DRAWINGS

The appended claims set forth the features of the invention with particularity. The invention, together with its advantages, may be best understood from the following detailed description taken in conjunction with the accompanying drawings of which:

5 FIG. 1A is a block diagram of an exemplary system employing one embodiment;

 FIG. 1B is a block diagram of a system or component thereof, such as, but not limited to a packet processor, lock mechanism, lock manager, distributor, gatherer, or resource used in one embodiment;

 FIGs. 2A-2C illustrate an ordered lock used in one embodiment;

10 FIGs. 3A-3D illustrate an ordered lock used in one embodiment;

 FIGs. 4A-D illustrate the concept of a lock conversion used in one embodiment;

 FIGs. 5A-D are a flow diagrams illustrating some of an unlimited number of embodiments for using ordered locks to maintain sequences of packets;

 FIG. 6A is a block diagram of an exemplary system using ordered locks to maintain
15 sequences of packets;

 FIG. 6B is a flow diagram illustrating a process using ordered locks processing using ordered locks to maintain sequences of packets;

 FIGs. 7A-D are diagrams illustrating messages communicated and operations performed in some of an extensible number of embodiments processing packets distributed
20 to packet processing engines; and

 FIG. 8 is a block illustrating the use of packet memory by one embodiment.

DETAILED DESCRIPTION

Disclosed are, *inter alia*, methods, apparatus, data structures, computer-readable medium, and mechanisms for using ordered locking mechanisms to maintain sequences of items which may include converting between ordered locking mechanisms. These items
5 may be anything, including, but not limited to packets and in which case, using ordered locks to maintain sequences of packets may be of particular use in routers, packet switching systems, and other devices.

Embodiments described herein include various elements and limitations, with no one element or limitation contemplated as being a critical element or limitation. Each of
10 the claims individually recites an aspect of the invention in its entirety. Moreover, some embodiments described may include, but are not limited to, *inter alia*, systems, networks, integrated circuit chips, embedded processors, ASICs, methods, and computer-readable medium containing instructions. One or multiple systems, devices, components, etc. may comprise one or more embodiments, which may include some elements or limitations of a
15 claim being performed by the same or different systems, devices, components, etc. The embodiments described hereinafter embody various aspects and configurations within the scope and spirit of the invention, with the figures illustrating exemplary and non-limiting configurations.

As used herein, the term "packet" refers to packets of all types or any other units of
20 information or data, including, but not limited to, fixed length cells and variable length packets, each of which may or may not be divisible into smaller packets or cells. The term "packet" as used herein also refers to both the packet itself or a packet indication, such as, but not limited to all or part of a packet or packet header, a data structure value, pointer or index, or any other part or direct or indirect identification of a packet or information
25 associated therewith. For example, often times a router operates on one or more fields of a packet, especially the header, so the body of the packet is often stored in a separate memory while the packet header is manipulated, and based on the results of the processing of the packet (i.e., the packet header in this example), the entire packet is forwarded or dropped, etc. Additionally, these packets may contain one or more types of information, including,
30 but not limited to, voice, data, video, and audio information. The term "item" is used generically herein to refer to a packet or any other unit or piece of information or data, a device, component, element, or any other entity. The phrases "processing a packet" and

"packet processing" typically refer to performing some steps or actions based on the packet contents (e.g., packet header or other fields), and such steps or action may or may not include modifying, storing, dropping, and/or forwarding the packet and/or associated data.

The term "system" is used generically herein to describe any number of
5 components, elements, sub-systems, devices, packet switch elements, packet switches, routers, networks, computer and/or communication devices or mechanisms, or combinations of components thereof. The term "computer" is used generically herein to describe any number of computers, including, but not limited to personal computers, embedded processing elements and systems, control logic, ASICs, chips, workstations,
10 mainframes, etc. The term "processing element" is used generically herein to describe any type of processing mechanism or device, such as a processor, ASIC, field programmable gate array, computer, etc. The term "device" is used generically herein to describe any type of mechanism, including a computer or system or component thereof. The terms "task" and "process" are used generically herein to describe any type of running program, including,
15 but not limited to a computer process, task, thread, executing application, operating system, user process, device driver, native code, machine or other language, etc., and can be interactive and/or non-interactive, executing locally and/or remotely, executing in foreground and/or background, executing in the user and/or operating system address spaces, a routine of a library and/or standalone application, and is not limited to any
20 particular memory partitioning technique. The steps, connections, and processing of signals and information illustrated in the figures, including, but not limited to any block and flow diagrams and message sequence charts, may typically be performed in the same or in a different serial or parallel ordering and/or by different components and/or processes, threads, etc., and/or over different connections and be combined with other functions in
25 other embodiments, unless this disables the embodiment or a sequence is explicitly or implicitly required (e.g., for a sequence of read the value, process the value- the value must be obtained prior to processing it, although some of the associated processing may be performed prior to, concurrently with, and/or after the read operation). Furthermore, the term "identify" is used generically to describe any manner or mechanism for directly or
30 indirectly ascertaining something, which may include, but is not limited to receiving, retrieving from memory, determining, defining, calculating, generating, etc.

Moreover, the terms "network" and "communications mechanism" are used generically herein to describe one or more networks, communications media or communications systems, including, but not limited to the Internet, private or public telephone, cellular, wireless, satellite, cable, local area, metropolitan area and/or wide area networks, a cable, electrical connection, bus, etc., and internal communications mechanisms such as message passing, interprocess communications, shared memory, etc. The term "message" is used generically herein to describe a piece of information which may or may not be, but is typically communicated via one or more communication mechanisms of any type.

The term "storage mechanism" includes any type of memory, storage device or other mechanism for maintaining instructions or data in any format. "Computer-readable medium" is an extensible term including any memory, storage device, storage mechanism, and other storage and signaling mechanisms including interfaces and devices such as network interface cards and buffers therein, as well as any communications devices and signals received and transmitted, and other current and evolving technologies that a computerized system can interpret, receive, and/or transmit. The term "memory" includes any random access memory (RAM), read only memory (ROM), flash memory, integrated circuits, and/or other memory components or elements. The term "storage device" includes any solid state storage media, disk drives, diskettes, networked services, tape drives, and other storage devices. Memories and storage devices may store computer-executable instructions to be executed by a processing element and/or control logic, and data which is manipulated by a processing element and/or control logic. The term "data structure" is an extensible term referring to any data element, variable, data structure, database, and/or one or more organizational schemes that can be applied to data to facilitate interpreting the data or performing operations on it, such as, but not limited to memory locations or devices, sets, queues, trees, heaps, lists, linked lists, arrays, tables, pointers, etc. A data structure is typically maintained in a storage mechanism. The terms "pointer" and "link" are used generically herein to identify some mechanism for referencing or identifying another element, component, or other entity, and these may include, but are not limited to a reference to a memory or other storage mechanism or location therein, an index in a data structure, a value, etc. The term "associative memory" is an extensible term, and refers to all types of known or future developed associative memories, including, but not limited to

binary and ternary content addressable memories, hash tables, TRIE and other data structures, etc. Additionally, the term "associative memory unit" may include, but is not limited to one or more associative memory devices or parts thereof, including, but not limited to regions, segments, banks, pages, blocks, sets of entries, etc.

5 The term "one embodiment" is used herein to reference a particular embodiment, wherein each reference to "one embodiment" may refer to a different embodiment, and the use of the term repeatedly herein in describing associated features, elements and/or limitations does not establish a cumulative set of associated features, elements and/or limitations that each and every embodiment must include, although an embodiment
10 typically may include all these features, elements and/or limitations. In addition, the phrase "means for xxx" typically includes computer-readable medium containing computer-executable instructions for performing xxx.

 In addition, the terms "first," "second," etc. are typically used herein to denote different units (e.g., a first element, a second element). The use of these terms herein does
15 not necessarily connote an ordering such as one unit or event occurring or coming before another, but rather provides a mechanism to distinguish between particular units.

 Additionally, the use of a singular tense of a noun is non-limiting, with its use typically including one or more of the particular thing rather than just one (e.g., the use of the word "memory" typically refers to one or more memories without having to specify "memory or
20 memories," or "one or more memories" or "at least one memory", etc.). Moreover, the phrases "based on x" and "in response to x" are used to indicate a minimum set of items x from which something is derived or caused, wherein "x" is extensible and does not necessarily describe a complete list of items on which the operation is performed, etc.

 Additionally, the phrase "coupled to" is used to indicate some level of direct or indirect
25 connection between two elements or devices, with the coupling device or devices modifying or not modifying the coupled signal or communicated information. The term "subset" is used to indicate a group of all or less than all of the elements of a set. The term "subtree" is used to indicate all or less than all of a tree. Moreover, the term "or" is used herein to identify a selection of one or more, including all, of the conjunctive items.

30 Disclosed are, *inter alia*, methods, apparatus, data structures, computer-readable medium, and mechanisms for using ordered locking mechanisms to maintain sequences of items which may include converting between ordered locking mechanisms. These items

may correspond to anything, including, but not limited to packets, data items, processes, threads, etc. However, using ordered locks to maintain sequences of packets, especially for maintaining requisite packet orderings when distributing packets to be processed to different packet processing engines, may be particularly useful.

5 One embodiment identifies a particular item, and in response, generates a locking request to an ordered lock. The ordered lock is configured to maintain a locking queue of identifiers corresponding to locking requests in the order requested. One or more instructions are associated with the particular identifier, and when the particular identifier reaches the head of the locking queue, the one or more instructions are performed.

10 In one embodiment, the instructions are associated with the particular identifier in an operation performed subsequently to the locking request. In one embodiment, the instructions are associated with the particular identifier in an operation performed after another identifier corresponding to a second locking request is added to the locking queue. In one embodiment, the locking queue contains multiple other identifiers corresponding to
15 other items when the locking request for the particular item is performed. In one embodiment, the one or more instructions include a lock conversion instruction to associate the particular item with a second ordered lock. In one embodiment, the particular item is a packet. In one embodiment, the one or more instructions include a packet gather instruction. In one embodiment, one or more fields of the particular packet are processed to
20 identify a secondary ordered lock, and the one or more instructions include a lock conversion instruction to associate the particular item with a second ordered lock.

One embodiment repeatedly identifies a particular packet, and in response, generates a locking request to an ordered lock, wherein the ordered lock maintains a locking queue of identifiers corresponding the locking requests in the order requested.

25 Acceptances requests corresponding to packets are communicated to the ordered lock. The ordered lock repeatedly removes a particular identifier from the head of the locking queue, and grants a locking acceptance request corresponding to the particular identifier if a corresponding acceptance request was previously generated, or waits until the locking acceptance request corresponding to the particular identifier is generated and then granting
30 the locking acceptance request corresponding to the particular identifier.

In one embodiment, the locking requests are non-blocking and acceptance requests are blocking. In one embodiment, in response to granting the locking acceptance request

corresponding to a packet, the packet is forwarded. In one embodiment, in response to granting the locking acceptance request corresponding to a packet, a second locking request corresponding to the packet to a particular secondary lock is made, with the particular secondary lock being identified based on contents of the packet.

5 One embodiment includes multiple packet processors, an ordered lock manager, and a distributor. The ordered lock manager is configured to receive lock requests, to receive instruction requests corresponding to the lock requests, and to process instructions corresponding to the lock requests in the order the lock requests are received and after an immediately prior lock request is released. The distributor is configured to receive a packet,
10 make a locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to one or more processors. At least one of the one or more processors is configured to communicate a set of instructions corresponding to the packet to the ordered lock manager.

 In one embodiment, the set of instructions includes a packet gather instruction. In
15 one embodiment, the set of instructions includes an instruction for performing a lock release. In one embodiment, the set of instructions includes a convert instruction for performing a secondary locking request.

 One embodiment includes one or more locking mechanisms, multiple packet processors, and a packet distributor. The one or more locking mechanisms operates
20 multiple ordered locks, including a root ordered lock and multiple secondary ordered locks. Each ordered lock including a queue for storing locking items. Each locking mechanism is configured to receive locking requests and to place indications of the locking requests in corresponding queues of the ordered locks, and to receive and react to locking accepts and locking releases. The packet distributor is configured to receive packets, to make root
25 ordered locking requests for each of the packets, and to distribute each of the packets to the packet processors. Each packet processor is configured to receive a particular packet, to accept a root ordered lock corresponding to the root ordered locking request for the particular packet, to process the packet to identify a secondary lock, to make a locking request corresponding to the secondary lock, and to release the root ordered lock. In one
30 embodiment, each packet processor is configured to make the lock request corresponding to the secondary lock after accepting the root ordered lock corresponding to the root ordered locking request for the particular packet and before releasing the root ordered lock.

One embodiment processes packets by distributing packets to packet processing engines while maintaining order of streams of packets using ordered locks. In response to a particular packet processing engine completing processing of a particular packet, a gather instruction is attached to the particular identifier of a particular ordered lock associated with the particular packet and the packet processing engine is released to be able to process another packet or perform another function. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, with the gather instruction causing the processed particular packet to be sent. The releasing of the packet processing engine is performed prior to performing the gather instruction. In one embodiment, performing the gather instruction includes communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet.

One embodiment receives a particular packet of a stream of packets. The packet is stored in a packet data storage and a packet handle data structure identifying the packet in the packet data storage is allocated. The particular packet is associated with a particular identifier of a particular ordered lock of one or more ordered locks. The particular packet is distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular packet, a gather instruction is attached to the particular identifier and the packet processing engine is released to be able to process another packet or perform another function. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, with performing the gather instruction including communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet. The gather mechanism receives a copy of the packet handle data structure, which is released after the gather mechanism receives the copy of the packet handle data structure. The releasing of the packet processing engine is performed prior to performing the gather instruction, and releasing the packet handle data structure is performed prior to the sending of the processed packet. In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of one or more ordered locks associated with the stream of packets to the particular ordered lock associated with the sub-stream.

One embodiment receives a particular packet of a stream of packets. The packet is stored in a packet data storage and a packet handle data structure identifying the packet in

the packet data storage is allocated. The particular packet is associated with a particular identifier of a particular ordered lock of one or more ordered locks. The particular packet is distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular packet, a gather instruction is attached to the particular identifier. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, with performing the gather instruction including communicating a gather request to a gather mechanism, wherein the gather mechanism prepares and sends the processed particular packet. The gather mechanism receives a copy of the packet handle data structure, and then the packet handle data structure is reused by the particular packet processing engine to perform further processing in response to the processing of the particular packet. The reusing of the packet handle data structure is commenced prior to the sending of the processed packet. In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of said one or more ordered locks associated with the stream of packets to the particular ordered lock associated with the sub-stream. In one embodiment, the further processing includes generating and sending a new packet.

One embodiment receives a particular packet of a stream of packets. The packet is stored in a packet data storage and a packet handle data structure identifying the packet in the packet data storage is allocated. The particular packet is associated with a particular identifier of a particular ordered lock of one or more ordered locks. The particular packet is distributed to a particular packet processing engine of a set of packet processing engines. In response to the particular packet processing engine completing processing of the particular packet, a gather instruction is attached to the particular identifier. The gather instruction is performed in response to the particular ordered lock being acquired by the particular identifier, which includes communicating a gather request to a gather mechanism, which prepares and sends the processed particular packet and then notifies the particular packet processing engine. In response to this notification, the particular packet is further processed by the particular packet processing engine.

In one embodiment, the particular packet is associated with a sub-stream of the stream of packets, and the particular identifier is converted from a lock of said one or more ordered locks associated with the stream of packets to the particular ordered lock

associated with the sub-stream. In one embodiment, the further processing includes sending information contained in the particular packet to a different destination than that specified in the particular packet.

One embodiment includes multiple packet processing engines, an ordered lock
5 manager and a distributor. The ordered lock manager is configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released. The distributor is configured to receive a packet, make a locking request
10 corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing engine of the packet processing engines. The particular processing engine is configured to communicate one or more instructions corresponding to the packet to the ordered lock manager after completing processing of the packet, and after communication of said one or more instructions, the particular packet processing engine is
15 released so that it can process another packet.

In one embodiment, the ordered lock manager is configured to notify the distributor in response to receiving the set of instructions, and the distributor is configured to release the packet processing engine in response to said notification. In one embodiment, the one or more instructions includes a gather instruction for the packet. One embodiment includes
20 a gather mechanism, wherein the ordered lock manager is configured to communicate a gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier.

One embodiment includes multiple packet processing engines, an ordered lock
25 manager, a distributor, and a gather mechanism. The ordered lock manager configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released. The distributor is configured to receive a packet, make a
30 locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing engine of the packet processing engines, wherein the particular processing engine is configured to communicate one or more instructions

corresponding to the packet to the ordered lock manager after completing processing of the packet, wherein said one or more instructions includes a gather instruction for the packet. The ordered lock manager is configured to communicate a gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier, wherein the gather mechanism prepares and sends the processed particular packet and then notifies the particular packet processing engine. The particular packet processing engine is configured to further process the packet in response to receiving said notification. In one embodiment, the further processing includes sending information contained in the packet to a different destination than that specified in the packet.

FIG. 1A is a block diagram of an exemplary system employing one embodiment. Shown is a packet switching system with packet processors 101-102 and 104-105 interconnected by packet switch fabric 103. In one embodiment, one or more of the packet processors 101-102 and 104-105 uses ordered locking mechanisms to maintain required sequences of packets.

FIG. 1B is a block diagram of a system or component 120 thereof, such as, but not limited to a packet processor, lock mechanism, lock manager, distributor, gatherer, or resource used in one embodiment. In one embodiment, system or component 120 performs one or more processes corresponding to one of the flow diagrams illustrated or otherwise described herein.

In one embodiment, component 120 includes a processing element 121, memory 122, storage devices 123, and an interface 124 for receiving and sending packets, items, and/or other information, which are typically coupled via one or more communications mechanisms 129 (shown as a bus for illustrative purposes.) Various embodiments of component 120 may include more or less elements. The operation of component 120 is typically controlled by processing element 121 using memory 122 and storage devices 123 to perform one or more scheduling tasks or processes. Memory 122 is one type of computer-readable medium, and typically comprises random access memory (RAM), read only memory (ROM), flash memory, integrated circuits, and/or other memory components. Memory 122 typically stores computer-executable instructions to be executed by processing element 121 and/or data which is manipulated by processing element 121 for implementing functionality in accordance with the invention. Storage devices 123 are

another type of computer-readable medium, and typically comprise solid state storage media, disk drives, diskettes, networked services, tape drives, and other storage devices. Storage devices 123 typically store computer-executable instructions to be executed by processing element 121 and/or data which is manipulated by processing element 121 for
5 implementing functionality in accordance with the invention.

Sequences of items may be maintained using ordered locks. These items may correspond to anything, but using ordered locks to maintain sequences of packets may be particularly useful. One embodiment uses a locking request, acceptance, and release protocol. One embodiment associates instructions with locking requests such that when a
10 lock is acquired (e.g., the corresponding locking request is at the head of a locking queue), the locking mechanism executes or causes to be executed the associated instructions as an acceptance request of the lock is implied by the association of instructions (while in one embodiment, the acceptance is explicitly requested, and in which case, the start of the execution of these instructions will be the later of the acquisition of the lock or the receipt
15 of the acceptance request). In some applications, the ordering of the entire sequence of packets is not required to be preserved, but rather only among certain sub-sequences of the entire sequence of items, which can be accomplished by converting an initial root ordered lock (maintaining the sequence of the entire stream of items) to various other locks (each maintaining a sequence of different sub-streams of items).

20 One embodiment of a locking mechanism uses the following basic and extensible operations:

- request(lock_id) - The context requests a lock. A "context" typically refers to state and resources including processor engine, thread, etc. associated with a packet or other entity while it is being processed. If the requested lock is
25 available (i.e., no other context owns it) then a lock_grant is sent to the requesting context. If however the lock is in possession of another context, then the new request is queued until it moves to the front of the queue and the lock_grant is sent. It is a non-blocking operation, i.e., any code after the request but before the accept is not part of the critical section, and can be executed
30 before the lock_grant is received.
- accept(lock_id) - This is a blocking operation, which causes the requesting context to block until it holds the desired lock (i.e., lock_grant has been

received). Any code executed after the accept, but before the release is the critical section for this lock.

- release(lock_id) - This is the operation which releases the lock, and makes it available for other requesting contexts.

5 FIGs. 2A-2C illustrate an ordered lock 200 used in one embodiment. Turning to FIG. 2A, lock mechanism 201 performs the locking operations, and can be implemented in an unlimited number of ways, including, but not limited to a processing element and memory, discrete logic, a custom ASIC etc. In one embodiment, ordered lock 200 uses one or more locking queues 202 (or any other mechanism to maintain the order requests are received), typically one for each lock supported. In one embodiment, ordered lock 200 only
10 services a single lock, and thus no lock ID is required to identify a particular lock (e.g., a root lock, a secondary lock, etc.) In one embodiment, ordered lock 200 services multiple locks, with the particular ordered lock typically being identified by a lock ID (e.g., a unique value, etc.) or via another mechanism. Lock request queues 202 can be implemented in an
15 unlimited number of ways, such as in different memories, shift registers, a single memory with each queue element identified using a link list or other data structure, etc.

FIG. 2B illustrates a lock mechanism process used in one embodiment for processing lock requests. Processing begins with process block 220. As determined in process block 222, when a lock request is received or otherwise identified, then in process
20 block 224, an identifier corresponding to the identified lock request is placed at the end of the lock request queue corresponding to the request (e.g., that identified by a lock ID or other mechanism if more than one lock being supported by the locking mechanism). Processing then returns to process block 222. In this manner, the order that locking requests are received is maintained by the locking mechanism.

25 FIG. 2C illustrates a process used in one embodiment to process lock items/requests for each queue supported by the locking mechanism. Processing begins at process block 240. As determined in process block 242, when there is a lock identifier in the queue, then in process block 244, the indication corresponding to a lock request at the head of the queue is identified. As determined in process block 248, if an accept request corresponding
30 to the identifier has been received, then in process block 252, the accept request is granted. Processing then waits at process block 254 until a corresponding release request is received, and then the indication is removed from the head of the queue in process block

256, and processing returns to process block 242. Otherwise, as determined in process block 250, if a release request corresponding to the identification is received, processing proceeds directly to process block 256. Otherwise, processing returns to process block 248.

One embodiment of a locking mechanism uses the following basic and extensible operations:

- request(lock_id) - The context requests a lock. If the requested lock is available (i.e., no other context owns it) then a lock_grant is sent to the requesting context. If however the lock is in possession of another context, then the new request is queued until it moves to the front of the queue and the lock_grant is sent. It is a non-blocking operation, i.e., any code after the request but before the accept is not part of the critical section, and can be executed before the lock_grant is received.
- attach(operation+attributes, convert+dest_flow_id) - The attach actually consists of an implied accept (i.e., get to the front of the queue for the current flow_id), followed by do_action and/or convert to a new flow_id and finally release current lock. Embodiments may use different attach operations.

FIGs. 3A-3D illustrate an ordered lock 300 used in one embodiment. Turning to FIG. 3A, lock mechanism 301 performs the locking operations, and can be implemented in an unlimited number of ways, including, but not limited to a processing element and memory, discrete logic, a custom ASIC etc. In one embodiment, ordered lock 300 uses one or more locking queues 302 (or any other mechanism to maintain the order requests are received), typically one for each lock supported. In one embodiment, ordered lock 300 only services a single lock, and thus no lock ID is required to identify a particular lock (e.g., a root lock, a secondary lock, etc.) In one embodiment, ordered lock 300 services multiple locks, with the particular ordered lock typically being identified by a lock ID (e.g., a unique value, etc.) or via another mechanism. Lock request queues 302 can be implemented in an unlimited number of ways, such as different memories, shift registers, a single memory with each queue element identified using a link list or other data structure, etc. As illustrated, instructions 305 are associated with received lock requests, such as those identified by lock identifiers stored in lock request queue(s) 302. These instructions can be associated with the lock requests using an unlimited number of techniques, and these instructions can be stored in queue 302 or in one or more other data structures.

FIG. 3B illustrates a lock mechanism process used in one embodiment for processing lock requests. Processing begins with process block 320. As determined in process block 322, when a lock request is received or otherwise identified, then in process block 324, an identifier corresponding to the identified lock request is placed at the end of the lock request queue corresponding to the request (e.g., that identified by a lock ID or other mechanism if more than one lock being supported by the locking mechanism). Processing then returns to process block 322. In this manner, the order that locking requests are received is maintained by the locking mechanism.

FIG. 3C illustrates a process used in one embodiment to process instruction requests by a locking mechanism. Processing begins with process block 340. As determined in process block 342, when an instruction request is identified (e.g., received, etc.), then in process block 344, these instructions are associated with the lock request (e.g., a lock identifier in a locking mechanism, or via any other mechanism).

FIG. 3D illustrates a process used in one embodiment to process lock items/requests for each queue supported by the locking mechanism. Processing begins at process block 360. As determined in process block 362, when there is a lock identifier in the queue, then in process block 364, the indication corresponding to a lock request at the head of the queue is identified. Until instructions corresponding to the identifier have been identified (e.g., received or otherwise identified now or previously), processing remains at 366. After corresponding instructions have been identified, in process block 368, the instructions are performed by the locking mechanism and/or another processing mechanism.

These instructions may be blocking (e.g., the lock must complete before proceeding to a next instruction or other operation) or non-blocking (e.g., initiate an operation and proceed with other instructions or operations). In one embodiment, the performed instruction(s) may include initiating an operation and block until the operation is complete. In one embodiment, the performed instruction(s) may include initiating an operation and do not block until the operation is complete. In one embodiment, the performed instruction(s) may include initiating an operation and delay sending an acknowledgement indication to the lock requestor until the operation is complete while proceeding with other lock items in the queue. For example, an operation to gather parts of a packet from different memory locations and/or memories might be initiated, while the acknowledgement operation might

be delayed until the memory access or accesses have been completed so that the memory location(s) can be overwritten.

In process block 370, an acknowledgement message is sent to the requestor, with this acknowledgment message being sent immediately or delayed until some other operation is complete, and possibly proceeding with processing more locking items in the queue before such acknowledgement is sent. Processing returns to process block 362. From one perspective, the receipt of instructions acts as an implied lock acceptance request, or even in one embodiment, the acceptance is one of the instructions associated with a lock request or indication thereof.

FIGs. 4A-D illustrate the concept of a lock conversion used in one embodiment. Note, the number and type of lock conversions used is extensible and may vary among embodiments to match the requirements of the application. Locks can be used to maintain strong ordering of a stream of items. Additionally, locks can be used to induce ordering of items. For example, a lock can be converted to multiple different locks which allows the same order to be maintained within the different locks, while allowing the items of the different locks to be processed in any order, such as, but not limited to being processed in parallel. Similarly, multiple locks can be converted to a single lock which induces ordering among items previously in the different locks (e.g., typically with the ordering being that in which locking requests are processed).

For example, packets arriving on an interface might each make a locking request in the order they are received to a single root lock, or make a locking request to one of multiple root locks (e.g., one for each receiving port, protocol type, packet type, etc., or some combination thereof). This maintains the order of the packets as the locks are processed in the order that the requests were made (e.g., the arrival order of packets in one embodiment). These locks can then be converted to different locks based on the processing of the packet required or some value included in the packet or other data structure, etc. For example, certain packet streams must maintain ordering. By converting all locks corresponding to the packets of the stream from a root lock to a same other lock, this ordering is maintained. Similarly, this second lock (or nth lock where n is any integer for that matter - as the number of possible locking conversions is unbounded) may be converted to another lock such as one corresponding to an output interface or port, and thus

the original ordering can be maintained (even if lock conversions from other locks are made to the same lock as the relative order within each stream is maintained by the lock).

Turning first to FIG. 4A, illustrated is an example of an ordered lock conversion 400. A stream of items 401 is processed by a ordered lock 402 (identified for simplicity as the "root lock"). When the root lock 402 is acquired by a particular identifier/item, if it is associated with a flow (also referred to as a sub-sequence or sub-stream) within stream 401, the ordered lock 404-406 corresponding to this flow is identified and a locking request is made to this secondary ordered lock 404-406. Note, ordered locks 402-406 can be implemented using one or more ordered lock mechanisms, with each lock implicitly identified or explicitly identified using a lock ID or other mechanism. Thus, the relevant ordering within the initial stream as maintained by root ordered lock 402 is transferred to each of the flow ordered locks 404-406, and the lock associated with an item is "converted" from root ordered lock 402 to one or more of the flow ordered locks 404-406.

FIG. 4B illustrates such processing used by a locking mechanism in one embodiment. Processing begins with process block 420, and proceeds to process block 422, wherein the acquired lock (e.g., indication explicitly or implicitly accepted at the front of the corresponding queue or other ordering mechanism) in the root lock is identified. Note, processing may need to wait until a lock is acquired. Next, in process block 424, a lock request is made in the flow ordered lock corresponding to the acquired lock.

Processing then returns to process block 422.

Similarly, conversion of locks 440 can be made from multiple flow locks 444-446 to another ordered lock 442 (identified for simplicity as the "root lock") as illustrated in FIG. 4C to produce a stream of items 441. When one of the multiple flow locks 444-446 is acquired by a particular identifier/item and a conversion operation is desired to root lock 442, a locking request is made to this secondary lock 442. Note, ordered locks 442-446 can be implemented using one or more ordered lock mechanisms, with each lock implicitly identified or explicitly identified using a lock ID or other mechanism.

FIG. 4D illustrates such processing used by locking mechanisms in one embodiment. Processing begins with process block 460, and proceeds to process block 462, wherein the acquired lock (e.g., indication explicitly or implicitly accepted at the front of the corresponding queue or other ordering mechanism) in an ordered lock is identified. Note, processing may need to wait until a lock is acquired. Next, in process block 464, a

lock request is made in an ordered lock. Processing then returns to process block 462. Thus, when this process is performed in connection by multiple flow ordered locks to a single root flow ordered lock, the original order of the items corresponding to the multiple flow ordered locks is maintained.

5 FIGs. 5A-D are a flow diagrams illustrating some of an unlimited number of embodiments for using ordered locks to maintain sequences of packets. Turning first to FIG. 5A, processing begins with process block 500, and proceeds to process block 502, wherein a packet is received and a corresponding ordered lock request is made. Next, in process block 504, the packet is processed. In process block 506, an acceptance request is
10 made to the ordered lock. In process block 508, when the lock is acquired, the packet is further processed, dropped, sent etc., and the lock is released. By waiting until the lock is acquired, the original ordering is maintained. Processing of the flow diagram is complete as indicated by process block 510.

 FIG. 5B illustrates a process used in one embodiment for processing packets using
15 ordered locking mechanisms. Processing begins with process block 520, and proceeds to process block 522, wherein a packet is received and a corresponding ordered lock request is made. Next, in process block 524, a secondary flow associated with a packet is identified. For example, an original stream of packets may be all packets received on an interface, and a particular flow might be identified based on a source address, destination
20 address, protocol type, quality of service requirement, group identification, and/or any other information contained in a packet or external to a packet. In one embodiment, all items belong to a secondary flow, which may include a default flow for packets not associated with another particular flow. In one embodiment, only some of the items belong to a secondary flow, and typically those packets not belonging to a secondary flow are
25 allowed to proceed as processed.

 In process block 526, an acceptance request to the root ordered lock, and typically the processing of the packet continues. In process block 528, when the lock is acquired, a lock request is made to the secondary ordered lock corresponding to the identified secondary flow. In process block 530, when processing of the packet is finished, an
30 acceptance request is made to the corresponding secondary ordered lock, and in process block 532, when the secondary ordered lock is acquired, the packet is further processed,

dropped, sent etc., and the lock is released. Processing of the flow diagram is complete as indicated by process block 534.

Processing of the flow diagram of FIG. 5C begins with process block 560, and proceeds to process block 562, wherein a packet is received and a corresponding ordered
5 lock request is made. Next, in process block 564, the packet is processed. In process block 566, when processing of the packet is complete, a set of one or more instructions is associated with the lock request. Note, the atomic operations to be performed in response to the instructions is extensible, and is typically defined in accordance with the needs of the application. For example, these atomic operations may include an operation including, but
10 not limited to conversion of locks, sequence number generation and/or checking, error checking and/or correcting, memory operations, data manipulation operations, initiating another operation, etc. In process block 568, when the lock is acquired, the instructions are executed by the lock mechanism or another mechanism, typically to further process, drop or gather/send packet, convert the root lock request, etc., and the lock is released. By
15 waiting until the lock is acquired before executing the instructions, the original ordering is maintained. Processing of the flow diagram is complete as indicated by process block 570.

FIG. 5D illustrates a process used in one embodiment for processing packets using ordered locking mechanisms. Processing begins with process block 580, and proceeds to process block 582, wherein a packet is received and a corresponding root ordered lock
20 request is made. Next, in process block 584, a secondary flow associated with a packet is identified. In process block 586, when processing of the packet is complete, a set of one or more instructions is associated with the lock request, with these instructions including a convert operation instruction. In process block 588, when the lock is acquired, the instructions are executed by the lock mechanism or another mechanism, to convert the root
25 lock to the identified secondary lock. In process block 590, when processing of the packet is complete, a set of one or more instructions is associated with the secondary lock request. In process block 592, when the lock is acquired, the instructions are executed by the lock mechanism or another mechanism, typically to further process, drop or gather/send packet, convert the root lock request, etc., and the lock is released. Processing of the flow diagram
30 is complete as indicated by process block 594.

FIG. 6A is a block diagram of an exemplary system using ordered locks to maintain sequences of packets. Packets 601 are received by packet processor 600 and typically

stored in packet memory 604 via multiplexor 602 (as packet processor allows for recirculation of packets from component 624). Distributor 606 is responsible for assigning a packet to one or more of the packet processing engines 610 for performing the actual packet processing. This processing may use cache 612, DRAM controls 614 and external
5 memory 615, lookup control 616, associative memory control 618 and associative memory 619, and/or other components which are typically accessed via coupled resource network 608. Distributor 606 also notifies lock manager and resequencer 620 of the assignment of the packet, and a root lock request is made. Packet processing engines 610 perform lock requests, acceptances, releases, attaching/associating instructions with lock requests in
10 conjunction with lock manager and resequencer 620. At the appropriate time, gather mechanism 622 is notified that a packet should be gathered and sent, for example based on a gather instruction associated with a lock request. A gather instruction typically defines how to accumulate or gather portions of a processed packet in order to form the processed packet, and may included the semantics to send the packet. Gathered packets are
15 communicated to buffer, queue, scheduler, memory control component 624 to send the processed packet as indicated by packets 629.

The operation of one embodiment of packet processor 600 and/or other packet processors is described in relation to FIG. 6B. Processing of which begins with process block 640, and proceeds to process block 642, wherein a packet is received and stored in
20 packet memory, and the distributor is informed of the arrival and location of the packet. In process block 644, the distributor identifies to which packet processing engine and possibly thread to assign to process the packet. In process block 646, the distributor notifies the packet processing engine of the assignment and makes a root locking request corresponding to the received stream to which the packet belongs, such as the interface on
25 which it was received. In one embodiment, the stream is identified based on the packet contents, but other embodiments minimize the processing of the packet performed by the distributor. The distributor also makes a locking request on behalf of the assigned packet processing engine to the lock manager for the packet. In process block 648, the assigned packet processing engine retrieves the relevant portion (e.g., header and possibly other
30 fields) of the packet from the packet memory, and processes this and/or other information to identify a secondary flow / lock, if any, to which the packet is associated and continues processing the packet.

As determined in process block 650, if a convert operation is to be performed, then in process block 652, the packet processing engine associates/attaches a convert instruction to the root lock request, and when the root lock is acquired, such as the corresponding identifier reaches the front of the root lock queue, the lock manager performs (or causes
5 another mechanism to perform) instructions to convert the lock and then releases the root lock.

Next, in process block 654, when processing of the packet is complete, the packet processing engine attaches a gather instruction to the secondary or root lock request (depending on whether an ordered lock conversion operation was performed). When this
10 lock is acquired, the lock manager performs (or causes another mechanism to perform) instructions to gather the fields of the packet to form the packet to be sent, and forwards the packet. Processing of the flow diagram is complete as indicated by process block 656.

FIGs. 7A-D are diagrams illustrating messages communicated and operations performed in some of an extensible number of embodiments processing packets distributed
15 to packet processing engines. FIG. 7A illustrates the initial processing performed in one embodiment to process a packet. Then, the processing illustrated in one or more of FIGs. 7B-D is performed to gather and send the packet, and possibly perform some post-processing (e.g., sending another packet, performing some other operation, etc.) before the particular packet processing engine is released to process another packet. Of course, each
20 packet processing engine / packet processor is typically processing a packet concurrently while the other packet processing engines / packet processors are processing their respective packets. Also, the order of some of the operations illustrated in FIGs. 7A-D may vary depending on times required for identifiers to be acquired by a flow lock, packet processing operations, etc.

Turning to FIG. 7A, illustrated are some operations performed by and messages
25 passed among in one embodiment including packet memory 700, distributor 702, flow lock manager 704, and packet processing engine (PPE) 706. Note, the terms packet processor and packet processing engines are often used interchangeably herein to describe a generic unit that processes packets. Note, FIGs. 7B-D also illustrate operations performed
30 by and communication with packet gather mechanism 708.

A particular packet is received (710) and stored (711) into packet memory 700, with a packet handle data structure which describes where the actual packet data is stored being allocated (711).

For example, FIG. 8 illustrates the use of packet memory 800 in one embodiment.

5 As shown, packet memory 800 includes the actual packet data stored in packet data 821-829. For a subset of those packets (e.g., those whose processing is not complete), packet handle data structures 811-819 typically include descriptors of such packet data. This will typically vary among embodiments, but such descriptors may include one or more pointers to the actual packet data, possibly with individual pointers to the packet header and to the
10 packet payload, etc., and possibly size information, etc. A packet handle data structure 811-819 is typically accessed using its corresponding packet handle 801-809 (i.e., a pointer, offset value, or other reference value). Note, in one embodiment, a packet handle data structure is typically used by a packet processing engine to access a data portion of packet memory 800, whether that corresponding to a received packet or for some other
15 operation.

Returning to FIG. 7A, a packet handle corresponding to the packet data structure associated with the received packet is communicated (712) to the distributor 702, which allocates (713) a free packet processing engine if one is currently available, or does so after one becomes available, and informs (714) packet memory 700 of the assigned packet
20 processing engine. In order to maintain the sequence of the received packets, distributor 702 performs a root flow lock request (715) to flow lock manager 704 and informs flow lock manager 704 of the assigned packet processing engine and the packet handle. Flow lock manager 704 performs (716) the root lock request for the packet and notifies (717) the distributor, which in turn notifies (718) the assigned packet processing engine 706 that it
25 can start processing the packet. Note, in one embodiment, notification 718 also serves to acknowledge the completion of the processing of the previous packet.

Typically, a router or packet switch will have a stream of packets received at an interface, which includes multiple sub-streams (e.g., different types of traffic, different priorities, different sources, etc.). It is important that these sub-streams be maintained in
30 order, while the order of the overall packet stream is not required to be maintained.

Therefore, a flow lock convert instruction will typically be attached to the root flow lock corresponding to the packet to convert the flow lock to that corresponding sub-stream of

packets. So, before such a convert operation can be issued, a packet processing engine typically determines to which sub-stream the packet belongs.

Thus, packet processing engine 706 requests (719) and receives (721) the packet header and possibly other fields and/or information corresponding to the packet from packet memory 700. In one embodiment, packet memory 700 retrieves (720) this information based on the identification of packet processing engine 706 (e.g., it maintains a data structure relating PPEs to packet handles, and thus can identify the corresponding packet handle data structure, and thus the actual packet data). Based on this information, packet processing engine 706 categorizes (722) the packet to identify the finer (e.g., secondary) lock corresponding to the sub-stream to which to convert, and submits (723) such a request to flow lock manager 704, which similarly identifies (724) the lock identifier corresponding to the packet (e.g., based on the identification of packet processing engine 706) and adds (724) such a conversion instruction, and notifies (725) that the conversion has been attached to the flow lock identifier. Packet processing engine 706 continues to process (726) the packet. When the lock identifier is acquired (727) by the root flow lock, its attached instructions are performed (727) which includes the conversion to the flow lock associated with the sub-stream.

This is a typically packet processing initial scenario performed in one embodiment. FIG. 7B-7D illustrate a few of an extensible number of scenarios which may occur in one embodiment to complete the processing of the packet. Briefly, FIG. 7B illustrates a basic processing of the packet which releases the assigned packet processing engine as soon as processing is complete and the packet gathering operation has been off-loaded to the gather mechanism. FIG. 7C illustrates a processing of the packet which retains and resets the corresponding packet handle data structure to allow post-processing including creation and sending of a new packet, and FIG. 7D further retains the packet data itself so post processing of the original packet can be performed.

As shown in FIG. 7B, processing (726) of the packet continues. Upon completion, packet gather, convert flow lock to null (i.e., don't convert it), and release flow lock instructions are sent (731) to flow lock manager 704, which attaches (732) them to the flow lock identifier corresponding to the packet, and in response, flow lock manager 704 notifies (733) distributor 702 that packet processing engine 706 is done, and distributor 702 releases it for processing of another packet. Depending on the traffic load, packet

processing engine 706 will be immediately assigned another packet to process, assigned another packet to process before the just processed packet is built and/or sent (e.g., the gather operation is performed), or after the processed packet is actually built and/or sent.

When the lock identifier corresponding to the packet is acquired (734) by the flow
5 lock, flow lock manager 704 issues (735) a gather command to packet gathering
mechanism 708 and includes the packet handle corresponding to the packet. Packet
gathering mechanism 708 then gets (736) (e.g., requests and receives) a copy of the packet
handle data structure and then releases (736) the packet handle and the packet handle data
structure so it can be used for processing other packets. The gather request is enqueued
10 (737) with this information by packet gathering mechanism 708. When the gather request is
serviced (e.g., at the head of the gathering queue to which it was enqueued) the actual
packet data is requested (738) and received (739), the packet is built and sent (740), and the
packet data space is released (741) within packet memory 700. Note, in one embodiment, a
single gathering queue is used; while in one embodiment, multiple gathering queues are
15 used, typically with the gathering queues be distinguished by one or more characteristics,
such as, but not limited to priority and/or type of traffic, QoS, scheduling information, etc.

As shown in FIG. 7C, processing (726) of the packet continues. Upon completion, a
packet gather (with fast acknowledgement - i.e., perform processing as described in FIG.
7C) instruction is sent (760) to flow lock manager 704, which attaches (761) them to the
20 flow lock identifier corresponding to the packet.

When the lock identifier corresponding to the packet is acquired (762) by the flow
lock, flow lock manager 704 issues (763) a gather command to packet gathering
mechanism 708 and includes the packet handle corresponding to the packet. Packet
gathering mechanism 708 then gets (764) (e.g., requests and receives) a copy of the packet
25 handle data structure and then resets but doesn't release (765) the packet handle data
structure. The gather request is enqueued (765) with this information by packet gathering
mechanism 708. Packet gathering mechanism 708 then notifies (766) that the gather
request is enqueued, and in response, packet processing engine 706 can perform some post
processing 767, typically in response to the processing of the packet just completed. This
30 can be administrative or any other processing, such a copy of a portion of the packet data
retained in its local memory. It may release its current flow lock, or convert it to the same
or a different flow lock. It may also perform some processing and/or then perform

processing illustrated in FIGs 7B, 7C or 7D, for example. This post processing is quite flexible in order to meet the needs of the application.

Note, as illustrated in FIG. 7C, packet processing engine 706 then still has an active packet handle and packet handle data structure which it can use to create a new packet in response to the processing of the previous packet, and then have the packet gathered (e.g., built and sent). It was important to keep a packet handle data structure so that a newly created packet can be sent, as the gather mechanism in one embodiment gathers a packet based on the information contained in a packet handle data structure retrieved from packet memory 700 based on a packet handle. This newly created packet could be anything, such as sending an administrative message in response to the contents of the packet (e.g., an error encountered, or the packet included a virus or other information of interest, etc.).

The sending of the processed packet typically proceeds as normal as further illustrated in FIG. 7C. When the gather request is serviced (e.g., at the head of the gathering queue to which it was enqueued (i.e., there may be more than one queue - possibly distinguished such as by priority, type of traffic, QoS, scheduling information, etc.), the actual packet data is requested (770) and received (771), the packet is built and sent (772), and the packet data space is released (773) within packet memory 700.

As shown in FIG. 7D, processing (726) of the packet continues. Upon completion, a packet gather (with slow acknowledgement - i.e., perform processing as described in FIG. 7D) instruction is sent (781) to flow lock manager 704, which attaches (782) them to the flow lock identifier corresponding to the packet.

When the lock identifier corresponding to the packet is acquired (783) by the flow lock, flow lock manager 704 issues (784) a gather command to packet gathering mechanism 708 and includes the packet handle corresponding to the packet. Packet gathering mechanism 708 then gets (785) (e.g., requests and receives) a copy of the packet handle data structure (and doesn't reset nor release the packet handle data structure). The gather request is enqueued (786) with this information by packet gathering mechanism 708.

The sending of the processed packet typically proceeds as normal as further illustrated in FIG. 7D. When the gather request is serviced (e.g., at the head of the gathering queue to which it was enqueued (i.e., there may be more than one queue - possibly distinguished such as by priority, type of traffic, QoS, scheduling information, etc.), the actual packet data is requested (790) and received (791), the packet is built and

sent (792) (and the packet data space is not released within packet memory and thus remains available to packet processing engine 706). Packet gathering mechanism 708 then notifies (793) that the packet was sent, and in response, packet processing engine 706 can perform some post processing 794, typically in response to the processing of the packet just completed. This can be administrative or any other processing, such a copy of a portion of the packet data retained in its local memory. It may release its current flow lock, or convert it to the same or a different flow lock. It may also perform some processing and/or then perform processing illustrated in FIGs 7B, 7C or 7D, for example. This post processing is quite flexible in order to meet the needs of the application. In contrast to the processing illustrated in FIG. 7C, that of FIG. 7D has available the original packet data of the previous processed packet in packet memory 700 accessible via the original packet handle and packet handle data structure. Thus, a copy of the packet can be sent to a different destination for multicast, security monitoring, or for any other purpose.

In view of the many possible embodiments to which the principles of our invention may be applied, it will be appreciated that the embodiments and aspects thereof described herein with respect to the drawings/figures are only illustrative and should not be taken as limiting the scope of the invention. For example and as would be apparent to one skilled in the art, many of the process block operations can be re-ordered to be performed before, after, or substantially concurrent with other operations. Also, many different forms of data structures could be used in various embodiments. The invention as described herein contemplates all such embodiments as may come within the scope of the following claims and equivalents thereof.

CLAIMS

What is claimed is:

1. A method for processing packets, the method comprising:

distributing a plurality of packets to a plurality of packet processing engines while
5 maintaining order of one or more streams of packets using one or more ordered locks, said
distributing including distributing a particular packet of the plurality of packets to a
particular packet processing engine of the plurality of packet processing engines with the
particular packet being associated with a particular identifier of a particular ordered lock of
said one or more ordered locks;

10 in response to the particular packet processing engine completing processing of the
particular packet, attaching a gather instruction to the particular identifier and releasing the
packet processing engine to be able to process another packet or perform another function;
and

performing the gather instruction in response to the particular ordered lock being
15 acquired by the particular identifier, said gather instruction causing the processed particular
packet to be sent;

wherein said releasing the packet processing engine is performed prior to said
performing the gather instruction.

2. The method of claim 1, wherein said performing the gather instruction includes
20 communicating a gather request to a gather mechanism; wherein the gather mechanism
prepares and sends the processed particular packet.

3. A method for processing packets, the method comprising:
receiving a particular packet of a stream of packets;
storing the packet in a packet data storage and allocating a packet handle data
structure identifying the packet in the packet data storage;
5 associating the particular packet with a particular identifier of a particular ordered
lock of one or more ordered locks;
distributing the particular packet to a particular packet processing engine of a
plurality of packet processing engines;
in response to the particular packet processing engine completing processing of the
10 particular packet, attaching a gather instruction to the particular identifier and releasing the
packet processing engine to be able to process another packet or perform another function;
and
performing the gather instruction in response to the particular ordered lock being
acquired by the particular identifier, said gather instruction including communicating a
15 gather request to a gather mechanism, wherein the gather mechanism prepares and sends
the processed particular packet; and
receiving by the gather mechanism a copy of the packet handle data structure, and
releasing the packet handle data structure after the gather mechanism receives the copy of
the packet handle data structure;
20 wherein said releasing the packet processing engine is performed prior to said
performing the gather instruction, and said releasing the packet handle data structure is
performed prior to the sending of the processed packet.

4. The method of claim 3, wherein the particular packet is associated with a sub-
stream of the stream of packets, and the method includes converting the particular
25 identifier from a lock of said one or more ordered locks associated with the stream of
packets to the particular ordered lock, wherein the particular ordered lock is associated
with the sub-stream.

5. A method for processing packets, the method comprising:

receiving a particular packet of a stream of packets;

storing the packet in a packet data storage and allocating a packet handle data structure identifying the packet in the packet data storage, the packet handle data structure;

5 associating the particular packet with a particular identifier of a particular ordered lock of one or more ordered locks;

distributing the particular packet to a particular packet processing engine of a plurality of packet processing engines;

10 in response to the particular packet processing engine completing processing of the particular packet, attaching a gather instruction to the particular identifier; and

performing the gather instruction in response to the particular ordered lock being acquired by the particular identifier, said gather instruction including communicating a gather request to a gather mechanism, wherein the gather mechanism prepares and sends the processed particular packet;

15 receiving by the gather mechanism a copy of the packet handle data structure; and reusing the packet handle data structure after the gather mechanism receives the copy of the packet handle data structure by the particular packet processing engine to perform further processing in response to said processing of the particular packet;

20 wherein said reusing the packet handle data structure is commenced prior to the sending of the processed packet.

6. The method of claim 5, wherein the particular packet is associated with a sub-stream of the stream of packets, and the method includes converting the particular identifier from a lock of said one or more ordered locks associated with the stream of packets to the particular ordered lock, wherein the particular ordered lock is associated the sub-stream.

7. The method of claim 5, wherein said further processing includes generating and sending a new packet.

8. A method for processing packets, the method comprising:
receiving a particular packet of a stream of packets;
associating the particular packet with a particular identifier of a particular ordered
lock of one or more ordered locks;
5 distributing the particular packet to a particular packet processing engine of a
plurality of packet processing engines;
in response to the particular packet processing engine completing processing of the
particular packet, attaching a gather instruction to the particular identifier; and
performing the gather instruction in response to the particular ordered lock being
10 acquired by the particular identifier, said gather instruction including communicating a
gather request to a gather mechanism, wherein the gather mechanism prepares and sends
the processed particular packet and then notifies the particular packet processing engine;
and
further processing of the particular packet by the particular packet processing
15 engine in response to said notification.

9. The method of claim 8, wherein the particular packet is associated with a sub-
stream of the stream of packets, and the method includes converting the particular
identifier from a lock of said one or more ordered locks associated with the stream of
packets to the particular ordered lock, wherein the particular ordered lock is associated
20 with the sub-stream.

10. The method of claim 8, wherein said further processing includes sending
information contained in the particular packet to a different destination than that specified
in the particular packet.

11. An apparatus for processing packets, the apparatus comprising:

a plurality of packet processing engines;

an ordered lock manager configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to
5 said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released; and

a distributor, coupled to the plurality of packet processing engines and the ordered lock manager, configured to receive a packet, make a locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing
10 engine of the plurality of packet processing engines;

wherein the particular processing engine is configured to communicate one or more instructions corresponding to the packet to the ordered lock manager after completing processing of the packet, and after said communication of said one or more instructions, the particular packet processing engine is released so that it can process another packet.

15 12. The apparatus of claim 11, wherein the ordered lock manager is configured to notify the distributor in response to receiving the set of instructions, and the distributor is configured to release the packet processing engine in response to said notification.

13. The apparatus of claim 11, wherein said one or more instructions includes a gather instruction for the packet.

20 14. The apparatus of claim 13, comprising a gather mechanism, wherein the ordered lock manager is configured to communicate a gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier.

15. An apparatus for processing packets, the apparatus comprising:

a plurality of packet processing engines;

an ordered lock manager configured to receive lock requests, to receive instruction requests corresponding to said lock requests, and to process instructions corresponding to
5 said lock requests in the order said lock requests are received and after an immediately prior lock request in the order said lock requests are received is released; and

a distributor, coupled to the plurality of packet processing engines and the ordered lock manager, configured to receive a packet, make a locking request corresponding to the packet to the ordered lock manager, and to distribute the packet to a particular processing
10 engine of the plurality of packet processing engines, wherein the particular processing engine is configured to communicate one or more instructions corresponding to the packet to the ordered lock manager after completing processing of the packet, wherein said one or more instructions includes a gather instruction for the packet; and

a gather mechanism, wherein the ordered lock manager is configured to
15 communicate a gather request for the packet to the gather mechanism in response to acquiring a lock identifier associated with the packet, with said one or more instructions being associated with the lock identifier, wherein the gather mechanism prepares and sends the processed particular packet and then notifies the particular packet processing engine;

and wherein the particular packet processing engine is configured to further process
20 the packet in response to receiving said notification.

16. The apparatus of claim 15, wherein said further processing includes sending information contained in the packet to a different destination than that specified in the packet.

17. An apparatus for processing packets, the apparatus comprising:

means for distributing a plurality of packets to a plurality of packet processing engines while maintaining order of one or more streams of packets using one or more ordered locks, said means for distributing including means for distributing a particular
5 packet of the plurality of packets to a particular packet processing engine of the plurality of packet processing engines with the particular packet being associated with a particular identifier of a particular ordered lock of said one or more ordered locks;

means for attaching a gather instruction to the particular identifier and releasing the packet processing engine to be able to process another packet or perform another function
10 in response to the particular packet processing engine completing processing of the particular packet; and

means for performing the gather instruction in response to the particular ordered lock being acquired by the particular identifier, said gather instruction causing the processed particular packet to be sent;

15 wherein said releasing the packet processing engine is performed prior to said performing the gather instruction.

18. The apparatus of claim 17, wherein the particular packet is associated with a sub-stream of the stream of packets, and the apparatus includes means for converting the particular identifier from a lock of said one or more ordered locks associated with the
20 stream of packets to the particular ordered lock, wherein the particular ordered lock is associated with the sub-stream.

19. An apparatus for processing packets, the apparatus comprising:

means for receiving a particular packet of a stream of packets;

means for storing the packet in a packet data storage and allocating a packet handle data structure identifying the packet in the packet data storage;

5 means for associating the particular packet with a particular identifier of a particular ordered lock of one or more ordered locks;

means for distributing the particular packet to a particular packet processing engine of a plurality of packet processing engines;

10 means for attaching a gather instruction to the particular identifier and releasing the packet processing engine to be able to process another packet or perform another function, in response to the particular packet processing engine completing processing of the particular packet; and

15 means for performing the gather instruction in response to the particular ordered lock being acquired by the particular identifier, said gather instruction including communicating a gather request to a gather mechanism, wherein the gather mechanism prepares and sends the processed particular packet; and

means for receiving by the gather mechanism a copy of the packet handle data structure, and releasing the packet handle data structure after the gather mechanism receives the copy of the packet handle data structure;

20 wherein said releasing the packet processing engine is performed prior to said performing the gather instruction, and said releasing the packet handle data structure is performed prior to the sending of the processed packet.

20. A apparatus for processing packets, the apparatus comprising:
means for receiving a particular packet of a stream of packets;
means for associating the particular packet with a particular identifier of a particular
ordered lock of one or more ordered locks;
5 means for distributing the particular packet to a particular packet processing engine
of a plurality of packet processing engines;
means for attaching a gather instruction to the particular identifier in response to the
particular packet processing engine completing processing of the particular packet; and
means for performing the gather instruction in response to the particular ordered
10 lock being acquired by the particular identifier, said gather instruction including
communicating a gather request to a gather mechanism, wherein the gather mechanism
prepares and sends the processed particular packet and then notifies the particular packet
processing engine; and
further processing of the particular packet by the particular packet processing
15 engine in response to said notification.

21. The apparatus of claim 20, wherein the particular packet is associated with a
sub-stream of the stream of packets, and the apparatus includes means for converting the
particular identifier from a lock of said one or more ordered locks associated with the
stream of packets to the particular ordered lock, wherein the particular ordered lock is
20 associated with the sub-stream.

22. The apparatus of claim 20, wherein said further processing includes sending
information contained in the particular packet to a different destination than that specified
in the particular packet.
