A method for non-surgically treating an internal nasal valve of a patient comprising, injecting a working device into the internal nasal valve of the patient, wherein the injected working device in the nasal tissue causes an alteration of an internal or external nasal valve. A device introduced by injection into the nose, allowing for structural support or tilting of defects in the nose, and causing a change in external shape of the nose. The device and inserts and implants described also have use in cosmetic applications relating to the facial tissue.

NASAL IMPLANT INTRODUCED THROUGH AN INJECTION TECHNIQUE

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation of and is based upon and claims the benefit of priority under 35 U.S.C. §120 for U.S. Ser. No. 12/507,697, filed Jul. 22, 2009, which is a divisional application of U.S. Ser. No. 11/898,768, filed Sep. 14, 2007. This application also claims the benefit of priority under 35 U.S.C. §119(e) for U.S. Provisional Application No. 60/846,736, filed on Sep. 25, 2006. The entire contents of each of these prior applications are incorporated herein by reference.

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

[0002] This invention has been created without the sponsorship or funding of any federally sponsored research or development program.

SEQUENCE LISTING OR PROGRAMS

FIELD OF THE INVENTION

[0004] The invention relates to methods, implants, and devices for non-surgically supporting the nasal valve, and achieving cosmetic changes to the shape of the nose (e.g., rhinoplasty). The device is introduced through an injectable method into the nasal tissue, and by specially designed suture.

BACKGROUND OF THE INVENTION

[0005] The information provided below is not admitted to be prior art to the present invention, but is provided solely to assist the understanding of the reader.

[0006] The internal nasal valve is the narrowest point in the nasal airway and is the point that often limits inspiration flow. A large percentage of inspiratory resistance is attributable to internal nasal valve function or malfunction. Collapse of one or both internal nasal valves is a common cause of nasal airway obstruction. Narrowness of the nasal valve may lead to difficulty in respiration and snoring as well as other breathing related disorders such as sleep apnea. Internal nasal valve collapse can be a consequence of previous surgery, trauma, aging, or primary weakness of the upper or lower lateral cartilage and is often symptomatic and debilitating.

[0009] The harvesting of a portion of the patient’s natural cartilage is an additional procedure and requires sculpting or other modification of the graft prior to use. Accordingly, surgically implanted synthetic nasal dilators, and non-surgical external dilators and cones have been suggested. An example of a surgically implanted dilator is found in U.S. Pat. No. 6,106,541 to Hubris dated Aug. 22, 2000. In the ’541 patent, the nasal dilator has a V-shape with an apex placed over the bridge of the nose to support the nasal tissue at the area of the internal valve. Other examples include U.S. Pat. No. 6,322,590 to Sillers et al., dated Nov. 27, 2001. However, use of such devices require an open surgical technique for insertion.

[0010] External (non-implanted) nasal dilators which are placed temporarily, and are removed by the patient are also available. Such external devices are possibly placed on the outside surface of the nose such as the “Breathe Right strips, U.S. Pat. No. 5,533,440, or U.S. Pat. No. 7,114,495 by Lockwood. Other devices may be placed in the nasal cavity (but not implanted in the nose), such as U.S. Pat. No. 7,085,525 given to Brown, and U.S. Pat. No. 6,978,781 given to Jordan. However, such devices can be uncomfortable, unsightly, and require the patient to remove and replace the device on a periodic basis.

[0011] Therefore, there is an urgent need for identifying methods and systems for repairing nasal valves and related nasal structures, including the repairing of the internal nasal valve collapse, which would eliminate the need for invasive surgical techniques. And thus eliminating risks and costs of general anesthesia and operating room expenses, and shorten recovery periods. It is also desirable to identify methods and systems that are implanted within the nose, eliminating the need for disposable external devices.

[0012] Unlike previous implant methods known and described, the implant of this invention is inserted by means of an injection technique, and does not require surgical incisions. It is inserted percutaneously or transnasally, usually under local anesthetic only. The implant may have different shapes and/or physical properties than previous implants described. This allows for it to be inserted by means of a non surgical technique, and the position may be adjusted initially after placement. One aspect of the invention would permit the implant to be adjusted after implantation.

[0013] Unlike previous nasal strips and dilators, the current invention provides a device and means whereby the device(s) is embedded within the tissue of the nose. It is designed to be
BRIEF SUMMARY OF THE INVENTION

[0014] Objects of the present invention include providing a method and system for treating internal nasal valve collapse. According to the present invention, this is achieved by non-surgical or minimally invasive treatment. Treatment of the internal nasal valve includes injecting a working implant into the tissue of the patient, affecting the internal nasal valve of the patient. The injection of the implant of this invention into the tissue surrounding internal nasal valve, according to the invention, causes an alteration or a change in the internal nasal valve angle.

[0015] In certain embodiments, the increase in internal nasal valve angle is affected by the working device which causes an increase in the structural strength of the tissue surrounding the nasal valve, thus preventing the tissue from collapsing during inspiration.

[0016] In another embodiment, the working device is injected into more lateral structures of the nose which causes adjustment of the position of the lateral aspect of the lateral nasal cartilage whereby affecting the external nasal valve.

[0017] In another embodiment, the working device is injected into more lateral structures of the nose, strengthening the lateral nasal cartilage, supporting the external nasal valve, and preventing collapse during inspiration.

[0018] In another embodiment, the working device is injected into more lateral structures of the nose, strengthening the attachments of lateral nasal cartilage to the bone adjacent to the piriform aperture, and supporting the external nasal valve, and preventing collapse during inspiration.

[0019] In another embodiment, the treatment method includes inserting an implant adjacent to lower lateral cartilage, the nasal dorsum, the paramedian tissue of the nasal dorsum, or the collumella to change the external shape of the nose.

[0020] In another embodiment, the implant is cylindrical in shape, though other shapes have also been described and fall within the scope of the present invention. The size is selected such that the implant can fit in the core of a needle (similar to a hypodermic needle). It is introduced into the nasal tissue by inserting the needle into the desired location. The implant is then maintained in that position by application of gentle pressure on the implant by an advancement shaft as the needle is withdrawn.

[0021] In another embodiment the implant has variable physical properties, depending on the particular application. Implants may have a rigid or flexible shape or configuration. The implant may be moldable such that the shape is changed and maintained just before or after implantation, or later modified as desired by the patient or as needed to obtain the results desired. Furthermore, implants can have shape-memory, with a tendency to return to its preset shape when deflected.

[0022] In another embodiment of the invention, the invention relates to an injection device for introducing the implant, which comprises of an introduction needle containing the implant.

[0023] In another embodiment the implant may have sutures attached at either or both ends, and a separate guiding needle attached to at least one end of one of the sutures. This needle may be passed along the desired path of the implant. The attached sutures can then be used to guide the implantation of the implant, and to adjust position in the tissue immediately after implantation. These sutures may then be trimmed as needed.

[0024] The treatment method, according to embodiments of the invention, may be used to treat nasal snoring, sleep apnea, and/or internal nasal valve collapse.

[0025] In another embodiment, a system for non-surgically treating the nasal valves of a patient or changing the shape of the nose includes an introducing needle, an implant present within the needle, an advancement shaft, and a handle portion. In certain embodiments of the invention, there may be a stop element to possibly control the movement of the advancement shaft after the introduction needle containing the implant is placed in the desired location.

[0026] In another embodiment, the system includes a pre-loaded syringe with a working device. In one embodiment, the working device is comprising a solid or a semi-solid material, or a hollow or a non-hollow cylinder of material. In another embodiment, the working device is comprising a woven mesh of material, biodegradable material, or a combination thereof.

[0027] In certain embodiments, the nasal implant proposed is an implant introduced into the nose through an injection technique, either transmucosally from inside the nose, or transcutaneously, from outside the nose.

[0028] The implant of the present invention is intended for insertion into the nose tissue and serves to augment or modify the structure of the nose and the nasal or flow passages. The implant provides support of nasal valves in the nose and may serve to fill defects and/or supplement or modify the contour of the nose in the manner desired for the purpose. The implant is introduced into a desired location within the nose or nasal passageway using an injection method. The implant is first incorporated into an injection device. The injection device may include a stop mechanism which serves to indicate when the implant is fully implanted.

[0029] The implant may be of any appropriate shape, including a cylindrical, an oval, or a rectangular and may include one or more tapered ends.

[0030] The implant of the present invention may be malleable, which would permit the shape of the implant to be adjusted before or after implantation. While not required, it may be preferred to use an implant made of a material which has shape memory properties. This property would permit the shape memory properties to be activated, or adjusted after implantation with the application of an external condition, such as temperature, magnetic field, or light.

[0031] In another embodiment of the invention, the implant may have spring like properties.

[0032] In another embodiments of the invention, the implant may be manufactured from a solid material, a composite of materials and may be a single material or may be a composite of one or more materials. The implant may be in the form of a rod or rod-like structure or may have a woven or braided structure. The implant may be woven or braided with several materials. In addition, the implant may be manufactured with biodegradable materials, including those with shape memory.

[0033] The implant may be introduced or injected through a transmucosal or transcutaneous route. The implant may be implanted within soft tissue of the nose in a location appropriate to provide the desired effect or result. When implanted into the soft tissue of the nose, the implant may serve to
support the soft tissue relative to the underlying bone structure. Further, the implant may be used to augment the lower lateral cartilages of the nose. In another aspect of the invention the implant may be placed in the nose superior or inferior to the nasal cartilage. Further it may be placed in a manner which will serve to augment the dorsum of the nose, or the columella and may additionally be placed in a paramedian location in the nose.

In another embodiment, the implant along with the inserting device and may be altered to be used in other areas of the body such as, but not limited to, naso-labial folds, lips, and marionette lines.

One embodiment of the invention is to provide a non-surgical approach for treating and eliminating these cosmetic conditions whether related to nasal valve problems or any other cosmetic related conditions.

The implant may be introduced into the desired location using a pull through technique, a guiding needle, or a combination of such techniques. The implant may be provided separately or with an injection device. Where desired the implant may incorporate a special pull through suture. The implant may additionally include a trailing suture. Where a pull through needle or trailing suture is used, both may be made or manufactured using materials which are dissolvable after the implant process is completed.

DESCRIPTION OF THE FIGURES

A more complete appreciation of the invention and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings, wherein:

FIG. 1 is a perspective view of the front, top and left side of a patient's nose showing skeletal components and cartilages. Labeled are the Nose (N), Nasal bone (NB), Left upper cartilage (LUC), Right upper lateral cartilage (RUC), septal cartilage (SC), Right lower lateral cartilage (RLC), and Left lower lateral cartilage (LLC), and Left accessory nasal cartilage (LANC).

FIG. 2 is a bottom plan view of the components of FIG. 1. In addition to the labels above, the Medial Crus (MC) and Lateral Crus (LC) are labeled, which together comprise the lateral cartilage. The Right Nose (RN) and Left nose (LN) are also labeled.

FIG. 3 is a right side elevation view of the components of FIG. 1. In this illustration, in addition to the labels above, the Right accessory nasal cartilage (RANC) is shown.

FIG. 4 is an oblique lateral view of the nasal structures. The nose dorsum has both a bony and a cartilaginous component to give the nose the lateral profile. The upper lateral cartilage (ULC), and lower lateral cartilages (LLC) are labeled, and give the nose its structure. The Maxillary bone (MB) is the bone of the maxilla adjacent to the nose. The nasal shape and valve is also affected by the strength of the attachment of the lower lateral cartilage to the maxillary bone.

FIG. 5 is a bottom plan view of the nose showing the relation of the lower lateral cartilage (LLC) to the Medial cartilage (MC) and both their relationship to the nasal airway (NA). The Right nasal airway (RNA) and left nasal airway (LNA) are illustrated.

FIG. 6 is a cross sectional view of the nose. The Lateral cartilage (LC) refers to either the upper or lower lateral cartilage, depending on the area of collapse. The Nasal valve angle (NVA) is the angle created by the lateral cartilage and the septum (S). The lateral cartilage in this case is thinner, and weaker, and there is corresponding narrowing of the nasal airway (NA) due to collapse and narrowing of the nasal valve.

FIG. 7 is a cross sectional view of the nose after implantation of an implant (I). The Lateral cartilage (LC) is supported by the implant, (I). The Nasal valve angle (NVA) is thus supported from collapsing during inspiration, widening the nasal airway (NA). In this case the implant is implanted on the outer surface of the lateral cartilage and septum (S).

FIG. 8 is an oblique lateral view of the nasal structures after implantation of an two implants acting as a batten grafts. The lower lateral cartilages (LLC) and Maxillary bones (MB) are labeled. The implants (I1) and (I2) give support to the lateral edge of the lower lateral cartilage, and strengthen its attachments to the maxillary bone. In this illustration, the implant (I1) is situated medial to the lower lateral cartilage, but overlying the maxillary bone, while implant (I2) is placed lateral to the lower lateral cartilage, and also lateral to the maxillary bone.

FIG. 9 is an oblique lateral view of the nasal structures after implantation of the proposed implants into other areas of the nose to achieve structural and cosmetic changes in the nose, not necessarily related to the nasal valve. Some of the implant locations proposed here and included for illustration purposes are: dorsal implants (D), used to modify the dorsal profile of the nose; Inferior Lower lateral cartilage Implant (ILLCI), which strengthens the lower lateral cartilage shape and form, thus also affecting the shape of the nose, and of the nasal tip; and Superior Lower Cartilage Implant (SLLCI) also used to modify the shape of the lower lateral cartilage, and the nasal form; and a Columella Implant (CI) used to give support to the columella.

FIG. 10 is an oblique lateral view of the nasal structures after implantation of the proposed implants into further areas of the nose to achieve structural and cosmetic changes in the nose. Shown here is an implant that is can be used as a Total Dorsal Profile Implant (TDPI), Paramedian Implants (PI), and Tip Implants (TI).

FIG. 11. The proposed modification to the nasal implant, where the implant, (a), has attached to it a guiding needle, (b), a "pull through" suture, (b), and a trailing suture, (d).

FIG. 12. The introducing device composed of the implant (d) placed in an introducing needle (e). There is the advancement shaft (c) which is used to advance the implant (d) into the desired location. The stop (b) prevents the thumb control (a) and advancement shaft (c) from advancing after the implant is expressed from the introducing needle, and placed in the desired location in the tissue. In the attachments FIGS. 12 A and B show an alternate arrangement in which the injector device (A) and the introduction needle and implant (B) are packaged separately, but can be attached through a locking attachment (f).

FIG. 13 Representative shapes of the nasal implants. The implants in general is elongated in shape having a length and side profile as shown in FIG. 13a. The side profile may be oval in shape (FIG. 13b), rectangular or oblong (FIG. 13c), or have tapered at the ends (FIG. 13d). Furthermore, it may be a hollow cylinder, or made of two or more materials (FIG. 13e).

FIG. 14. The standard introduction method of the implant, in this case implanted into the lateral nose, to support the external nasal valve. In FIG. 14A the introduction needle containing the implant is first introduced through the nasal
mucosa, and deep to the lower lateral cartilage. The introduction needle is then advanced into the desired location for the implant (FIG. 14-2). The introduction needle is then withdrawn, as the implant is maintained in position by advancing the advancement shaft (FIG. 14-3). After removal of the introduction needle, the implant is now present in the desired location (FIG. 14-4). In certain situations, the implants shape may then be adjusted after implantation to assume the desired shape (FIG. 14-5).

FIGS. 15(a)-(b). The introduction method using the additional introduction modification shown in FIG. 11. In FIG. 15(a)-1 through 15(a)-3, the guiding needle is first introduced and passed along the path through which the implant will be placed. The "pull through" suture is then advanced. The implant is then advanced, usually with the guide of an introduction needle system as shown in FIG. 15(b)-1. The introduction needle is removed while the advancement shaft is advanced to maintain the implant in the desired location (FIG. 15(b)-2). The pull through and trailing sutures may then used to finely adjust the position of the implant after implantation (FIG. 15(b)-6). The sutures are then cut at the skin or mucosal surface FIG. 15(b)-7.

DESCRIPTION OF THE PREFERRED EMBODIMENT

0053 Referring now to the drawings, wherein like reference numerals designate identical or corresponding parts throughout the several views.

0054 Before the subject invention is described further, it is to be understood that the invention is not limited to the particular embodiments of the invention described below, as variations of the particular embodiments may be made and still fall within the scope of the appended claims. It is also to be understood that the terminology employed is for the purpose of describing particular embodiments, and is not intended to be limiting. Instead, the scope of the present invention will be established by the appended claims.

0055 In this specification and the appended claims, the singular forms "a," "an" and "the" include plural reference unless the context clearly dictates otherwise. Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which this invention belongs.

0056 Where a range of values is provided, it is understood that each intervening value, to the tenth of the unit of the lower limit unless the context clearly dictates otherwise, between the upper and lower limit of that range, and any other stated or intervening value in that stated range, is encompassed within the invention. The upper and lower limits of these smaller ranges may independently be included in the smaller ranges, and are also encompassed within the invention, subject to any specifically excluded limit in the stated range. Where the stated range includes one or both of the limits, ranges excluding either or both of those included limits are also included in the invention.

0057 Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which this invention belongs. Although any methods, devices and materials similar or equivalent to those described herein can be used in the practice or testing of the invention, the preferred methods, devices and materials are now described.

0058 All publications mentioned herein are incorporated herein by reference for the purpose of describing and disclosing the subject components of the invention that are described in the publications, which components might be used in connection with the presently described invention.

0059 The information provided below is not admitted to be prior art to the present invention, but is provided solely to assist the understanding of the reader.

0060 The details of one or more embodiments of the invention are set forth in the accompanying drawings and the description below. Other features, objects, and advantages of the invention will be apparent from the description and drawings, and from the claims.

0061 The structure of the lower two thirds of the nose is determined primarily by the nasal septal cartilage, and paired upper and lower lateral cartilages, covered by a soft tissue envelope [FIGS. 1-4]. Structural weakness of these cartilages, or their attachments may result in deleterious functional and cosmetic changes to the nose. The nasal valves may collapse contributing to a dynamic nasal obstruction. Internal and external nasal valves exist.

0062 The internal nasal valves are formed by the angle of the septum and the lower edge of the upper lateral cartilage [FIG. 5]. During inspiration, air flow creates a negative pressure on the cartilage, resulting in a collapse of the nasal walls, as seen in FIG. 6. This leads to nasal obstruction. In some cases there may also be collapse of the nasal valve at rest, resulting in a constricted airway even at rest which is further exacerbated with inspiration.

0063 The external valve is formed by the shape of the lower lateral cartilage, and the strength of the attachments of these lower lateral cartilages to the lateral anterior maxillary bone. Weakening of this lateral cartilage also leads to nasal airway obstruction which is exacerbated with inspiration.

0064 Nasal patency is critical to the airway, and nasal obstruction can contribute to snoring, sleep apnea, and disrupted sleep. The patency of a good nasal airway is also critical for the growing number of people using continuous positive airway pressure (CPAP) for sleep apnea.

0065 Collapse and weakening of the nasal cartilage can also lead to external deformities and cosmetic changes to the nose. Loss of support and volume of the lower lateral cartilages, mid-nasal portion or the dorsum can lead to undesirable cosmetic changes. Relative tissue defects on the dorsum of the nose may lead to an irregular nasal profile. These cosmetic differences have traditionally been addressed by surgical rhinoplasty.

0066 Common causes of nasal cartilage and nasal valve collapse today are prior surgery or trauma that weakens the cartilage, age, or congenital weakness of the nasal cartilage.

0067 Current therapies to correct nasal valve collapse include several non-surgical and surgical devices and techniques. Non-surgical devices include external splints placed on the nasal surface which splay the lateral nasal walls outwardly, thus widening the nasal airway. External strips are such an external device (U.S. Pat. Nos. 5,533,440, 6,238,411, 6,982,359, 7,114,495). Other devices previously proposed include cone shaped applicators placed into the nostril, or dilators having a variety of proposed shapes (U.S. Pat. Nos. 7,055,523, 6,978,781).

0068 Surgical therapies for repair of the valve collapse include insertion of spreader grafts (for internal valve collapse), button grafts (for external valve collapse), or suspension sutures. These are placed through surgical incision techniques, or external rhinoplasty approach. The grafts are most commonly harvested from septal or auricular cartilage.
Implants (e.g., stents) made from alloplastic materials inserted surgically through an external approach have also been described (U.S. Pat. Nos. 6,106,541, 6,454,803, 6,322,590, 2,173,848). These prevent the morbidity or limitations of homografts, but still require an incision surgical technique for placement.

Implants introduced through injection technique have been introduced into the palate and used for the treatment of snoring and sleep apnea (U.S. Pat. No. 7,077,144).

With reference to the figures provided herewith, in which identical elements are numbered identically throughout, a description of the preferred embodiment of the present invention will now be provided.

A. Anatomy

Before proceeding with a description of the apparatus and method of the present invention, a review of relevant anatomy will facilitate an understanding of the present invention. FIGS. 1-3 show in perspective, bottom plan and right side elevation, respectively, components of the nose with skeletal muscle, soft tissue (such as external skin or nasal mucosa) and blood vessels removed.

The nose N includes nasal bone NB at an upper end of the nose. The bottom of the nose N includes the lower cartilage also referred to as the major alar cartilage. There is both a right lower cartilage LLC and a left lower cartilage LLC, which are generally symmetrical in structure.

The lower cartilages LLC, LLC include an external component referred to as the lateral crus LC and an internal component referred to as the medial crus MC. The medial crus and septal nasal cartilage create a nasal septum NS which divide the nose N into a left nostril L and a right nostril R.

Upper cartilages reside between the lower cartilages and the nasal bones NB. The upper cartilages include both a right upper cartilage RUC and a left upper cartilage LUC separated by a septal cartilage SC extending down the bridge of the nose N. The opposing edges of the lower cartilage LLC, LLC and upper cartilage LUC, RUC may move relative to one another. Disposed between the opposing edges is an accessory nasal cartilage (left and right) LANC, RANC.

When congested, during inhalation, airflow through the nostrils creates an inward pressure at the junction between the upper and lower cartilages. This pressure is expressed as a function of nasal resistance which is estimated as 10 centimeters of water per one liter per second. Cole, “The Four Components of the Nasal Valve”, American Journal of Rhinology, pages 107-110 (2003).

In response to these forces, a weakened nasal valve may collapse inwardly as illustrated in FIG. 6. In FIG. 6, it will be appreciated that the inward deflection is exaggerated for ease of illustration. It will be noted with reference FIG. 5 that the narrow angle between the LLC and the MC illustrated in FIG. 6, and the relative weakness of the LLC contribute to the inward deflection and collapse of the airway.

B. Implant

1. The Implant:

The implant to be used in the present invention should be adapted for deployment in a nose. Thereto, the implant should be adapted for introduction into the nose of a patient, to be reliably positioned or installed within said nose and/or to be retained in said nose. The adaptation may be such that the form (or shape) of the implant is adapted or preformed to the anatomy of the nose for which it is intended. For example, the location in the nose and the required effect (e.g. bulking only or stiffening) may dictate that different shaped implants, or implants with different materials be used. The implant is self-holding when imbedded in the tissue.

Implants that can be used in the present invention include metallic implants, polymeric implants, biodegradable implants and covered or coated implants. They may be composed of a variety of metal compounds and/or polymeric materials, fabricated in innumerable designs, composed of degradable and/or nondegradable components, fully or partially covered with graft materials (such as the so called “covered stents”) or “sleeves”, and can be bare metal or drug-eluting.

The implants may be comprised of a metal or metal alloy such as stainless steel, spring tempered stainless steel, stainless steel alloys, gold, platinum, super elastic alloys, cobalt-chromium alloys and other cobalt-containing alloys (including ELGILOY (Combined Metals of Chicago, Grove Village, Ill.), PHYNOX (Alloy Wire International, United Kingdom) and CONICHRONE (Carpenter Technology Corporation, Wyomissing, Pa.)), titanium-containing alloys, platinum-tungsten alloys, nickel-containing alloys, nickel-titanium alloys (including nitinol), malleable metals (including tantalum); a composite material or a clad composite material and/or other functionally equivalent materials; and/or a polymeric (non-biodegradable or biodegradable) material. Representative examples of polymers that may be included in the implant construction include polyethylene, polypropylene, polyurethanes, polyesters, such as polyethylene terphthalate (e.g., DACRON or MYLAR (E.I. DuPont De Nemours and Co., Wilmington, Del.)), polyamides, polyaramids (e.g., KEVLAR from E.I. DuPont De Nemours and Co.), polyfluorocarbons such as poly(tetrafluoroethylene with and without copolymerized hexafluoropropylene) (available, e.g., under the trade name TEFLOW (E.I. DuPont De Nemours and Co.), silk, as well as the mixtures, blends and copolymers of these polymers. Stents also may be made with engineering plastics, such as thermotropic liquid crystal polymers (LCP), such as those formed from p,p'-dihydroxy-polynuclear-aromatics or dicarboxy-polynuclear-aromatics.

Further types of implants (e.g., stents) that can be used with the described therapeutic agents are described, e.g., in PCT Publication No. WO 01/01957 and U.S. Pat. Nos. 6,165,210; 6,009,561; 6,071,305; 6,063,101; 5,997,468; 5,980,551; 5,980,566; 5,972,027; 5,968,092; 5,951,586; 5,893,840; 5,891,108; 5,851,231; 5,843,172; 5,837,008; 5,766,237; 5,769,883; 5,753,811; 5,700,286; 5,683,448; 5,679,400; 5,665,115; 5,649,977; 5,637,113; 5,591,227; 5,551,954; 5,545,208; 5,500,013; 5,464,440; 5,419,760; 5,411,550; 5,342,348; 5,286,254; and 5,163,952. Removable drug-eluting stents are described, e.g., in Lambert, T. (1993) J. Am. Coll. Cardiol.: 21: 483A. Moreover, the stent may be adapted to release the desired agent at only the distal ends, or along the entire body of the stent.

In addition to using the more traditional stents, stents that are specifically designed for drug delivery can be used. Examples of these specialized drug delivery stents as well as traditional stents include those from Conor Medsystems (Palo Alto, Calif.) (e.g., U.S. Pat. Nos. 6,527,789; 6,239,967; 6,290,673; 6,241,762; U.S. Patent Application Publication Nos. 2003/0199970 and 2003/0167085; and PCT Publication No. WO 03/015664).
Other examples of stents that can be used in accordance with the invention include those from Boston Scientific Corporation, (e.g., the drug-eluting TAXUS EXPRESS$^\text{TM}$ Paclitaxel-Eluting Coronary Stent System; over the wire stent stents such as the Express$^\text{TM}$ Coronary Stent System and NIR Elite OTW Stent System; rapid exchange stents such as the EXPRESS$^\text{TM}$ 2 Coronary Stent System and the NIR ELITE MONORAIL$^\text{TM}$ Stent System; and self-expanding stents such as the MAGIC WALLSTENT$^\text{TM}$ Stent System and RADIUS Self-Expanding Stent); Medtronic, Inc. (Minneapolis, Minn.) (e.g., DRIVER ABT578-eluting stent, DRIVER ZIPPER MX Multi-Exchange Coronary Stent System and the DRIVER Over-the-Wire Coronary Stent System; the ST ZIPPER MX Multi-Exchange Coronary Stent System; S7, S670, S660, and BESIENT$^\text{TM}$ 2 with Discetec Technology Over-the-Wire Coronary Stent System); Guidant Corporation (e.g., cobalt chromium stents such as the MULTI-LINK VISION$^\text{TM}$ Coronary Stent System; MULTI-LINK ZETA$^\text{TM}$ Coronary Stent System; MULTI-LINK PIXEL$^\text{TM}$ Coronary Stent System; MULTI-LINK ULTRA$^\text{TM}$ Coronary Stent System; and the MULTI-LINK FRONTIER$^\text{TM}$); Johnson & Johnson/Cordis Corporation (e.g., CYPHER sirolimus-eluting Stent; PAMELA$^\text{TM}$ Balloon Expandable Stent; and S.M.A.R.T. Stents); Abbott Vascular (Redwood City, Calif.) (e.g., MATRIX LO Stent; TRIMAXX$^\text{TM}$ Stent; and DEXAMET Stent); Conmed Systems (Menlo Park, Calif.) (e.g., RESTEN NG-coated stent); and Jomed (e.g., FLEXMASTER$^\text{TM}$ drug-eluting stent) (Sweden). Other types of stents can be in US20060147492A1: Medical implants and anti-scarring agents. The entire content of US20060147492A1 is incorporated herein by reference.

Generally, the implants are inserted in a similar fashion regardless of the site or the disease being treated. Briefly, a preinsertion examination is conducted by direct visualization, possible endoscopy, and rarely diagnostic imaging. The areas of structural defects, volume defects, of dynamic collapse of the nose are noted. The implant size and material is selected to suit the particular application, where more than one implant material and size may be available.

Topical local anesthetic may be applied by a combination of topical anesthetic cream applied to the skin (e.g. 4% lidocaine cream available commercially) and/or topical anesthetic solution (e.g. 4% lidocaine solution) applied on a cotton pledget in the nasal cavity. Local anesthetic may be infiltrated directly in the area where the implant will be placed, or also injected to perform regional blocks, such as an infraorbital nerve block.

The implant is then introduced through an injection technique as illustrated in this patent (for example, see FIG. 14). The implant is introduced through the injection method into the desired location in the nasal tissues. The introducing needle is gradually withdrawn, while the implant is maintained in its desired position by means of the advancement shaft of the introduction device. Generally, the puncture site performed by the introduction needle is small, and does not require repair.

After insertion, the implant shape may be adjusted manually. In some situations a special condition is applied to allow for adjustment of the shape of the implant. For example, in the case of an implant with certain physical properties, heat may be applied by external application of a heating pad to the nose. This is transmitted through the tissue to the implant which rises its temperature. The shape of the implant is then adjusted to the desired shape, and the external heat source is removed. The implant then maintains this new shape as it is cool.

A post-insertion examination, is performed to visually confirm that the desired structural and shape change to the nose has been achieved. Rarely, diagnostic imaging or endoscopy may also be used at this stage.

Implants are typically maneuvered into place directed by visual and tactile control. In certain aspects, the implant (e.g., stent) can further include a radio-opaque, echogenic material, or MRI responsive material (e.g., MRI contrast agent) to aid in visualization of the device under ultrasonography, fluoroscopy and/or magnetic resonance imaging. The radio-opaque or MRI visible material may be in the form of one or more markers (e.g., bands of material that are disposed on either end of the implant).

As suitable implant materials, both organic and inorganic materials, as well as combinations thereof may be used. The material of the implant may be solid, (e.g. titanium, nitinol, or Gore-tex), braided or woven from a single material (such as Titanium, or Polyethylene Terephthalate, or a combination of materials). The woven materials may have pores which allow ingrowth of tissue after implantation. It may be manufactured from biodegradable materials (e.g. poly-L-lactic, Poly-D-lactic, and poly-L-glycolic acid) which will gradually absorb after implantation. It may be malleable, allowing adjustment of the shape before, or after implantation.

Synthetic polymers provide for very suitable organic implant (e.g., stent) materials. Advantages of such polymers include the ability to tailor mechanical properties and degradation kinetics to suit various applications. Synthetic polymers are also attractive because they can be fabricated into various shapes. Numerous synthetic polymers can be used to prepare synthetic polymer-comprising stents useful in aspects of the invention. They may be obtained from sources such as Sigma Chemical Co., St. Louis, Mo., Polysciences, Warrenton, Pa., Aldrich, Milwaukee, Wis., Fluka, Ronkonkoma, N.Y., and BioRad, Richmond, Calif.

Representative synthetic polymers include alkyl cellulose; cellulose esters, cellulose ethers, hydroxyalkyl cel-
luloses, nitrocelluloses, polyalkylene glycols, polyalkylene oxides, polyalkylene terephthalates, polyalkylene, polyamides, polyanhydrides, polycarbonates, polyesters, polyglycolides, polymers of acryl and methacryl esters, polyacrylamides, polyorthoesters, polypeptides, polysiloxanes, polyurethanes, polyvinyl alcohols, polyvinyl esters, polyvinyl ethers, polyvinyl halides, polyvinylpyrrolidone, poly(ether ether ketones, silicone-based polymers and blends and copolymers of the above. The stent may comprise both oligomers and polymers of the above.

[0094] Specific examples of the broad classes of polymers include poly(methyl methacrylate), poly(ethyl methacrylate), poly(butyl methacrylate), poly(isobutyl methacrylate), poly(hexyl methacrylate), poly(isodecyl methacrylate), poly(lauryl methacrylate), poly(phenyl methacrylate), poly(methyl acrylate), poly(isopropyl acrylate), poly(isobutyl acrylate), poly(2-octadecyl acrylate), polyethylene, polypropylene, poly(ethylene glycol), poly(ethylene oxide), poly(ethylene terephthalate), poly(vinyl alcohols), poly(vinyl acetate), poly(vinyl chloride), polyurethanes, polyethylene, poly(lactic acid), poly(butyric acid), poly(valeric acid), poly(lactic acid), poly(lactic-co-glycolide), poly(fumaric acid), poly(maleic acid), copolymers of poly(caprolactone) or poly(lactic acid) with polyethylene glycol and blends thereof.

[0095] The polymers used in implants (e.g., stents) may also be biodegradable. Examples of preferred non-biodegradable polymers include ethylene vinyl acetate (EVA), poly(methyl acrylate, polyanhydrides, silicone-based polymers and copolymers and mixtures thereof.

[0096] Polymers used in implants (e.g., stents) may also be biodegradable. The rate of degradation of the biodegradable stent is determined by factors such as configurational structure, copolymer ratio, crystallinity, molecular weight, morphology, stresses, amount of residual monomer, porosity and site of implantation. The skilled person will be able to choose the combination of factors and characteristics such that the rate of degradation is optimized.

[0097] Examples of preferred biodegradable polymers include synthetic polymers such as polyanhydrides, poly(ortho)esters, polycarbonates, and natural polymers and polymers derived therefrom such as albumin, alginate, casein, chitin, ch[embedded image not shown]s, collagen, dextran, elastin, proteoglycans, gelatin[embedded image not shown] and other hydrophilic proteins, glutin, zein and other prolamine and hydrophobic proteins, starch and other polysaccharides including cellulose and derivatives thereof (e.g., methyl cellulose, ethyl cellulose, hydroxypropyl cellulose, hydroxypropyl methyl cellulose, hydroxybutyl methyl cellulose, carboxymethyl cellulose, cellulose acetate, cellulose propionate, cellulose acetate butyrate, cellulose acetate phthalate, cellulose acetate succinate, hydroxypropylmethylcellulose phthalate, cellulose acetate triacetate, cellulose sulphate), poly-1-lysine, polyethyleneimine, poly(allyl amine), poly(hyaluronic acids, and combinations, copolymers, mixtures and chemical derivatives thereof (substitutions, additions of chemical groups, for example, alkyl, alkenyl, hydroxylations, oxidations, and other modifications routinely made by those skilled in the art). In general, these materials degrade either by enzymatic hydrolysis or exposure to water in vivo, by surface or bulk erosion. The foregoing materials may be used alone, as physical mixtures (blends), or as a co-polymer.

[0098] Other polymers are polyesters, polyanhydrides, polystyrenes and blends thereof. The polymers and polyanhydrides are advantageous due to their ease of degradation by hydrolysis of ester linkage, degradation products being resorbed through the metabolic pathways of the body in some cases and because of their potential to tailor the structure to alter degradation rates. The mechanical properties of the biodegradable material are preferably selected such that early degradation and concomitant loss of mechanical strength required for it’s functioning as a structure supporting implant is prevented.

[0099] Biodegradable polymers are for instance poly(glyceric acid) (PGA), poly(lactic acid) (PLA), poly(glycolic-co-lactic acid) (PLGA), poly(dioxanone), poly(caprolactone) (PCL), poly(3-hydroxybutyrate) (PHB), poly(3-hydroxyvalerate) (PHV), poly(lactide-co-caprolactone) (PLCL), poly(vinylactone) (PVL), poly(tertronic acid), poly(3-maleic acid), poly(propylene fumarate) (PPF) (preferably photo cross-linkable), poly(ethylene glycol)/poly(lactic acid) (PELA) block copolymer, poly(l-lactic acid e-caprolactone) copolymer, and poly(lactide)-poly(ethylene glycol) copolymers.

[0100] Biodegradable polyanhydrides are for instance poly[1,6-bis(carboxyphenoxy)hexane], poly(fumaric-co-sebacic) acid or P(FA:SA), and such polyanhydrides may be used in the form of copolymers with polylimides or poly(anhydrides-co-imides) such as poly[4,4′-methylenebisphenol glycol] (PCL), poly[pyromellitimidophthallic anhydride] (PPA), poly[bis(hydroxymethyl)ethyl methacrylate] (PMMA) and poly[ethylene glycol] (PEG). Polyol poly(anhydrides-co-imides) may also be used.

[0101] Other suitable stent materials are biocompatible materials that are accepted by the tissue surface. The broad term biocompatible includes also non-toxicity, noncarcinogenicity, chemical inertness, and stability of the material in the living body. Exemplary biocompatible materials are titanium, alumina, zirconia, stainless steel, cobalt and alloys thereof and ceramic materials derived thereof such as ZrO2 and or Al2O3.

[0102] As examples of inorganic implants (e.g., stents) materials calcium phosphate matrices (CaP) and hydroxyapatite (HA) matrices may be used, wherein HA may optionally be combined with tricalcium phosphate to form such compounds as biphasic calcium phosphate (BCP). CaP, sintered hydroxyapatite and bioactive glasses or ceramics, such as 4S5 Bioglass® (US Biomaterials Corp, USA), and apatite- and wollastonite-containing glass-ceramic (glass-ceramic A-W) may also be used. Very suitable matrix materials the combined materials such as osteoinductive hydroxyapatite (HA/BCP) matrices, preferably BCP.

[0103] One form of the nasal implant described here is introduced through an injection device. The implant (A) is elongated in shape having a length L. and side profile P [FIG. 13 a]. The side profile may be oval in shape, rectangular, or tapered at the ends [FIG. 13 b, c, and d]. Furthermore, it may be a hollow cylinder (FIG. 13e), or made of a composite of materials, or a braid of wires. They are introduced into the nose non-surgically through an injection device. The injection route may include transcutaneous route, i.e. through the nasal skin, or transmucosally, through the internal mucosa of the nose. The intention of this device is that it be introduced under local anesthetic.
The nasal implant may also incorporate an introduction needle and suture, and/or a trailing suture (FIG. 11). This provides an alternative method for introduction of the implant. The guiding needle is introduced through the skin, or mucosa, and tracked along the desired path to the location chosen for the implant and then to a location where it exits the body, such as through the skin. This guiding needle is introduced and directed by the physician's fingers, or using standard medical instruments. This method for introduction of the implant, which includes a “pull through” and trailing sutures is illustrated in FIGS. 15(a)-(b). After introduction of the “pull through” suture shown in FIGS. 15(a)-(b), the guiding needle may be cut off. The implant is then introduced with the injection device in FIG. 12, with the guidance of the “pull through” suture, as illustrated in FIGS. 15(a)-(b). Alternatively, it may be introduced without an injection device, but simply by guiding it to the desired location by gently pulling on the “pull through” suture. The trailing suture can also be used to make adjustments to the position of the implant in situ. When the desired position is accomplished, the “pull through” suture, and the trailing sutures are cut. The suture can be made of absorbable material. The suture may have a diameter similar to the diameter of the implant, or be smaller or larger.

The injector device allows the introduction of the implant into the body through an injection technique. Shown in FIG. 12, it incorporates the nasal implant (FIG. 14), an introducing needle (FIG. 14-a). The implants are introduced through an injection device either through the transcutaneous route or through the nasal mucosa. The implant is placed through a straight introducer device, or a specially curved introducer device, or may be malleable to allow for special shaping of the needle prior to injection.

These implants may be placed adjacent to the upper lateral cartilage, below the nasal surface, as illustrated in FIG. 7. This will apply lateral force to the medial portion of the lateral nasal cartilage, stenting the internal nasal valves open. It is an alternative to the spreader grafts currently placed surgically.

The implants may be placed adjacent to the lateral edge of the lower lateral cartilages. The implants may extend to the bony process of the anterior maxillary bone as illustrated in FIG. 8. This will secure the lateral cartilage more securely to the maxillary bone, preventing lateral nasal collapse. These implants may be placed to secure the external valve in place of alar batten grafts that are now employed and are applied surgically. They may be inserted overlying or underlying the lateral surface of the lower lateral cartilage.

The implants may have a straight or curved shape. Alternatively, they may have a malleable property, and can have the shape adjusted after implantation. They may also have shape memory properties (such as composed of Nitinol) which allows for their shape to assume a predetermined shape after implantation. Use of inserts made of materials which have shape memory properties permit the implant to assume a preset shape after insertion. Alternately, certain conditions may be applied, such as application of heat, cold, light, or a magnetic field, that will allow the material to assume a desired fixed or modified shape after implantation. The necessary condition will depend on the intrinsic properties of the shape memory material chosen to produce the implant. The fixed shape of the implant may also be adjusted before or after insertion. The implant may be composed of biodegradable materials, with or without shape memory.

Another aspect of this invention provides for the use of the described injectable implants for cosmetic changes to the nose. The implants may be introduced transcutaneously or transmucosally to improve the structural strength of the nasal cartilages, or to fill defects in the nasal contours. Examples of proposed areas where the implants can be placed include locations adjacent to the lower lateral cartilage as lateral alar implants, in the mid nasal region, and the nasal dorsum, or the columella, as illustrated in FIG. 9, and FIG. 10.

**EXAMPLES**

Three working examples of useful implants have been produced for insertion into the nose.

The first is a 1.4 cm long, 0.8 mm thick titanium rod that is incorporated in a 16 gauge injection needle. This is designed for use into the lateral nasal wall which supports the external valve. The implant is injected in a fashion similar to the technique illustrated in FIG. 14. The currently preferred method of introduction is transmucosally (from inside the vestibule of the nose). The implant is placed beneath the lower lateral cartilage and the nasal mucosa, and extends over the maxillary bone. When placed, it appears similar to the implant 11 shown in FIG. 8. One implant is placed for each side of the nose, if bilateral valve collapse is present. After implantation, the shape of the implant can be adjusted by molding the shape of the titanium implant.

In another example, a 1.8 cm long and 1 mm thick rod manufactured from a 85:15 poly (L-lactide-co-glycolide) polymer has been produced. It is introduced using a 14 gauge needle. This polymer is bio-absorbable. It is inserted transcutaneously over the medial portion of the nose, similar to the one shown in FIG. 7. After implantation, the material has some structural strength, and by providing an upward force on the medial portion of the upper lateral cartilage, it supports the internal nasal valve, preventing its collapse. The shape of the implant can be adjusted after implantation by temporarily placing a heating pad at 64 degrees Celsius on the surface of the nose. This temperature is tolerated by the human nose for a brief period of time. The temperature is transmitted to the implant, and at such a temperature the polymer softens, and the implant shape can manually adjusted. The implant retains the new shape as it cools.

The third example used is a tapered rod with an oval shaped cross section similar to the implant shown in FIG. 13b. The implant dimensions may be trimmed prior to implantation depending on the particular size desired for the particular patient to be implanted. This implant is manufactured from a porous polyethylene. It is inert, non-absorbable, and has a porous structural surface which allows for fibrovascular tissue ingrowth. It is introduced through a 14 gauge needle, into the dorsum of the nose, filling in volume defects in the nose. This is similar to the DI implant shown FIG. 9.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art of molecular biology. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described herein. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In case of conflict, the present specification, including definitions, will control.
In addition, the materials, methods, and examples are illustrative only and are not intended to be limiting.

EQUIVALENTS

[0115] Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.

[0116] Obviously, numerous modifications and variations of the present invention are possible in light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the invention may be practiced otherwise than as specifically described herein.

1. A delivery system, the delivery system comprising:
   an introducing needle;
   an implant having a length, width and thickness sized for said implant to reside within soft tissue of a nose and which will fit within a core of the introducing needle, wherein said implant has a stiffness to resist bending in the nasal tissue of the patient, and wherein the implant is structurally preformed to a desired shape or shapeable after insertion to alter the shape of tissue within the nose, wherein the implant further includes one or more sutures to assist in guiding the placement of the implant.

2. An apparatus for use in the treatment of a nasal valve condition of a patient's nose where said treatment includes placing an implant in soft tissue of the nose surrounding the internal nasal valve, said apparatus comprising:
   an introduction needle configured to contain the implant,
   the introduction needle comprising an advancement shaft, handle portion, and stop mechanism, the stop mechanism configured to control movement of the advancement shaft;
   an implant having a length, width and thickness sized for said implant to reside within the soft tissue of the nose and which will fit within a core of the introducing needle, wherein said implant further has a stiffness to resist bending in the nasal tissue of the patient, wherein the implant is structurally preformed to a desired shape or shapeable after insertion to alter the shape of tissue within the nose, and wherein the implant further comprises one or more sutures to assist in guiding the placement of the implant.

3. An apparatus for use in a treatment of a nasal valve collapse where said treatment includes placing of an implant in a nose, said apparatus comprising:
   an introduction needle configured to contain the implant,
   the introduction needle comprising an advancement shaft that controls movement of the implant out of the introduction needle;

an implant having a length, width and thickness sized for said implant to fit within a core of the introduction needle and to reside within the nose, wherein said implant is structurally preformed to a desired shape or shapeable after insertion to alter the shape of tissue within the nose, wherein the structure is further selected to have a stiffness that will resist bending of the nasal tissue of the patient, and wherein the implant further comprises a suture attached to and extending from each of a first and second end of the implant to assist in guiding the placement of the implant.

4. The apparatus according to claim 2, wherein the material for the implant is a bioabsorbable polymer selected from the group consisting of Poly-L-lactic acid, Poly-dl-lactic acid, Poly-e-caprolactone, and Poly-glycolic acid.

5. The apparatus according to claim 2, wherein the material for the implant is a metal or metal alloy selected from the group consisting of titanium-containing alloys, platinum-tungsten alloys, nickel-containing alloys, nickel-titanium alloys, nitinol, and malleable metals.

6. The apparatus according to claim 2, wherein the material for the implant is a polymer selected from the group consisting of polystyrene, polyethylene, and polypropylene.

7. The apparatus according to claim 2, wherein the implant is made of two or more materials.

8. The apparatus according to claim 2, wherein the implant further comprises magnetic resonance imaging visible material.

9. The apparatus according to claim 8, wherein the magnetic resonance imaging visible material comprises bands of material disposed on either end of the implant.

10. The apparatus according to claim 2, wherein the implant is made of braided or woven material from a single material, and wherein the braided or woven material comprises pores configured to allow ingrowth of tissue after implantation.

11. The system according to claim 1, wherein the implant includes a suture extending from a trailing end of the implant.

12. The system according to claim 11, wherein the suture is made of absorbable material.

13. The apparatus according to claim 3, wherein the introduction needle further comprises a stop mechanism that controls movement of the advancement shaft after the introduction needle arrives at a desired location in the nose.

14. The apparatus according to claim 1, wherein the sutures have a diameter substantially similar to a diameter of the implant.
