HIGH SPECIFIC CAPACITANCE AND HIGH POWER DENSITY OF PRINTED FLEXIBLE MICRO-SUPERCAPACITORS

[0001] This application claims the benefit of U.S. Provisional Application No. 61/714,820, filed on October 17, 2012. The entire teachings of the above application are incorporated herein by reference.

BACKGROUND OF THE INVENTION

[0002] Global demand for energy has increased rapidly due to the tremendous industrial development and fast growth of population [1]. As one of the most important energy storage devices, supercapacitors have recently attracted intensive research interests and innovation strategies [2, 3]. As compared to batteries, supercapacitors show advantageous features such as higher power density and faster charge-discharge rate [4]; however, the low energy density stored in the devices and difficulties in using them in a flexible and reliable way severely hampers their wider usage in a variety of applications.

[0003] Recent advances in nanoscience and nanotechnology have suggested that microsupercapacitors (MSCs), with electrode, channel and current collector, and having a size in the range of micrometers, possess one of the most promising designs for energy storage. Compared to conventional batteries and supercapacitors, research in the area of flexible supercapacitors or MSCs is just at its infancy. Depending on the active materials used, fabrication of MSCs may require different techniques, which need to be fully understood in terms of the device design, consolidation and testing procedures. For example, the laser writing (or scribing) method has been successfully demonstrated as a method suitable for the synthesis of graphene or graphene oxide MSCs [5, 6]. However, this same method is not amendable for the fabrication of metal oxides (a group of pseudo-supercapacitor active materials) MSCs. Except direct laser writing / scribing [5-8], multiple
technologies have been designed and developed for special MSCs fabrication, such as multilayer nanomembranes rolled-up [9], origami [10], conventional microelectronic-fabrication process [10-21], electrochemical deposition[22, 23], ink-jet printing [24], electrostatic spray deposition [25], and deep etching [26]. Moreover, most strategies involve various chemical treatments, complicated fabrication processes, and high costs, making them difficulty applied for commercialization or mass production. As such, most of the research efforts have concentrated on the particular active material and a general route to integrate various active materials into MSCs by same technology likewise is rarely reported in literatures.

SUMMARY OF THE INVENTION

[0004] In a first aspect, the present invention relates to a micro supercapacitor, comprising a substrate, a first metal electrode, a second metal electrode, an active material coating the first metal electrode and the second metal electrode, comprising manganese oxide (MnO₂), carbon nanostructures and optionally a binder, and an electrolyte. The first metal electrode and the second metal electrode can be located in the same plane on the substrate. The electrolyte can comprise a solid electrolyte.

[0005] The active material can also comprise a carbon nanostructure and/or a metal oxide. The carbon nanostructure can comprise onion like carbon, carbon nanotubes, conductive carbon black, or a combination thereof. In one embodiment, the active material comprises manganese oxide (MnO₂) deposited on the surface of onion-like carbon. In one embodiment, the active material comprises manganese oxide (MnO₂) and carbon nanotubes. In yet another embodiment, the active material comprises manganese oxide (MnO₂) and graphene.

[0006] The substrate can be comprise polyethylene terephthalate (PET), polyethylene naphthalate (PEN), polycarbonate (PC), polyethersulfone (PES), photographic paper, insulated thermal tape, or a combination thereof. The substrate can also be flexible.

[0007] The metal electrode can comprise a metal selected from silver (Ag), gold (Au), copper (Cu), aluminum (Al), platinum (Pt), or a combination or alloys thereof.
The first metal electrode and the second metal electrode can be patterned. For example, the first metal electrode and the second metal electrode can be patterned to create channels of varying widths between the first metal electrode and the second metal electrode. In one embodiment, the channel width between the first metal electrode and the second metal electrode is less than about 1 mm.

The binder can comprise a polymer or copolymer comprising vinylidene fluoride, trifluoroethylene, chlorotrifluoroethylene, tetrafluoroethylene, hexafluoropropylene, 1,1-chlorofluoroethylene, poly(methyl methacrylate), 11-aminoundecanoic acid, thiourea, or a combination thereof.

In another aspect, the present invention relates to a method of making a micro supercapacitor, comprising: a) screen printing a metal ink on a substrate to form a first metal electrode and a second metal electrode; b) drying the first metal electrode and the second metal electrode under vacuum and elevated temperature; c) screen printing an active material ink on top of the first metal electrode and the second metal electrode to form an active material on the first and second metal electrode; d) drying the active material on the first and second metal electrode at an elevated temperature; and e) drop-casting a solid electrolyte onto the active material on the first and second metal electrode to form the micro supercapacitor.

The present invention also relates to an active material, comprising manganese oxide (MnO₂) grown on the surface of onion-like carbon. The manganese oxide (MnO₂) grown on the surface of onion-like carbon can form a nanocomposite having a diameter between about 50 nm and about 400 nm. In one embodiment, the nanocomposite exhibits a flower-like structure composed of manganese oxide (MnO₂) nanoribbons radiating from the onion-like carbon center of the nanocomposite.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing will be apparent from the following more particular description of example embodiments of the invention, as illustrated in the accompanying drawings in which like reference characters refer to the same parts.
throughout the different views. The drawings are not necessarily to scale, emphasis
instead being placed upon illustrating embodiments of the present invention.

[0012] FIG. 1(a) is a schematic illustration of a carbon nanotube micro
supercapacitor (CNT-MSC). FIG. 1(b) is a schematic illustration of the carbon
nanotube micro supercapacitor (CNT-MSC) fabrication process using the screen
printing technology.

[0013] FIG. 2(a) is a picture of a flexible carbon nanotube micro supercapacitor
(CNT-MSC). FIGs. 2(b) and 2(c) are scanning electron microscope (SEM) images
of a carbon nanotube (CNT) active material printed on a silver (Ag) electrode.

[0014] FIG. 3(a) is a plot of the potential in volts at various current densities
over time in seconds (charge/discharge curves) of a screen printed carbon nanotube
micro supercapacitor (CNT-MSC) measured in liquid electrolyte where a saturated
calomel electrode (SCE) is used as the reference electrode. FIG. 3(b) is a plot of the
specific capacitance in mF/cm² and specific power values in mW/cm² at various
current densities (mA/cm²). FIG. 3(c) is a plot of cyclic voltammetry (CV) at
various scan rates (e.g., about 1 mV/s to about 100 mV/s). FIG. 3(d) is a plot of the
capacity retention of CNT-MSC at a current density of 0.4 mA/cm² over several
cycles. The insert in FIG. 3(d) depict possible applications for CNT-MSCs.

[0015] FIG. 4(a) is a photograph of a solid flexible carbon nanotube micro
supercapacitor (CNT-MSC) with a channel size of 1000 μm. FIG. 4(b) is a plot of
the potential in volts at various current densities (μA/cm²) over time of a solid
flexible CNT-MSC. FIG. 4(c) is a plot of the capacity in mF/cm² over a range of
current densities (μA/cm²) of a solid flexible CNT-MSC. FIG. 4(d) is a plot of the
current in mA at various scan rates over a range of potentials (about 1 mV/s to about
100 mV/s) of a solid flexible CNT-MSC.

[0016] FIG. 5 (a) and FIG. 5(b) are field emission scanning electron
micrographs (FESEM) of a manganese oxide/onion-like carbon (MnO₂/OLC)
nanocomposite active material morphology at two different magnifications and scale
bars (1 μm and 200 nm). FIG. 5(c) is a schematic diagram of the proposed growth
mechanism of the oxide/onion-like carbon (MnO₂/OLC) nanocomposite synthesized
by hydrothermal method.
FIG. 6(a) is a transmission electron micrograph of the nanoribbons formed upon the growth of manganese oxide (MnO₂) on the surface of the onion-like carbon (OLC). FIG. 6(b) is an energy dispersive X-ray (EDX) spectrum of the manganese oxide/onion-like carbon (MnO₂/OLC) active material (nanocomposite).

FIG. 7(a) is a photograph of solid flexible manganese oxide/onion-like carbon micro supercapacitors (MnO₂/OLC-MSCs) with the channel width of 600 μm. FIG. 7(b) to FIG. 7(d) is the electrochemical characterization of the solid flexible MnO₂/OLC-MSC. FIG. 7(b) is a plot of the potential in volts at various current densities (μA/cm²) over time (charge/discharge curves) of a solid flexible MnO₂/OLC-MSC. FIG. 7(c) is a plot of the specific capacitance in mF/cm² over a range of current densities (μA/cm²) of a solid flexible MnO₂/OLC-MSC. FIG. 7(d) is a plot of the cyclic voltammetry (CV) at various scan rates (e.g., 5 mV/s to about 50 mV/s) of a MnO₂/OLC-MSC.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to printable micro supercapacitors (MSCs), with carbon nanostructures and carbon nanostructure/metal oxide nanocomposites employed as the active materials. Micro supercapacitor may help solve several major existing challenges in supercapacitor operation. The high surface-to-volume ratios in the active materials of the present invention together with micrometer diffusion channels can provide flexible MSCs with not only high volumetric capacity [11], but also with high power densities and high energy densities [5, 7, 27]. MSCs of the present invention have high charge-discharge rates due to the shortened diffusion length (as shown in FIG. 1(a)) [11]. The flexible MSCs of the present invention can be used to drive circuit on chip micro-electromechanical systems (MEMS), or can be integrated with next generation flexible electrical and electronic devices to power wearable circuits [5].

In one aspect, the present invention relates to a micro supercapacitor, comprising a substrate, a first metal electrode, a second metal electrode, an active material coating the first metal electrode and the second metal electrode, and an electrolyte. The active material can comprise manganese oxide (MnO₂) and/or a
carbon nanostructure and optionally can further comprise a binder. The first metal electrode and the second metal electrode coat the substrate and are located in the same plane on the substrate.

[0021] The substrate can be rigid or flexible and transparent or opaque. For example, the substrate can be glass, quartz, boron nitride, silicon with silicon dioxide (SiO₂) on top, plastics, polyethylene terephthalate (PET), polyethylene naphthalate (PEN), polycarbonate (PC), polyethersulfone (PES), photographic paper, insulated thermal tape, or a combination thereof. The identity of the substrate is determined by the particular application for which the MSC is being used.

[0022] The metal electrodes or current collectors (1 in FIG. 1) can comprise one or more metals or a metal alloy. The metal of the metal electrode should be a conductor that is compatible with the temperature for deposition of carbon nanostructure (e.g., between about 50 °C to about 250 °C). The metal electrode is formed through the printing of the metal ink onto the substrate using screen printing technology followed by drying of the resulting metal electrode (e.g., in an oven). Examples of metals that may be used in fabricate the metal electrode include, but are not limited to, silver (Ag), gold (Au), copper (Cu), aluminum (Al), platinum (Pt), or combinations or alloys thereof. The first metal electrode and the second metal electrode can be the same or different. For example, the first and second electrodes can be a silver (Ag) electrode or the first electrode can be a silver (Ag) electrode and the second electrode can be a gold (Au) electrode.

[0023] In one embodiment, the metal electrode can be patterned. The first metal electrode and the second metal electrode can be patterned on the substrate to create a pattern with channels between the first metal electrode and the second metal electrode (FIG. 1). For example, the first and second electrodes can be patterned into an interdigital shape as depicted in FIGs. 1(b) and 2(a). The pattern is not limited to an interdigital shape and may include other patterns. The channel between the first and second electrodes can have a width less than about 1 mm, preferably less than about 0.3 mm, more preferably less about 0.1 mm.

[0024] The printed metal electrode should to be dried at an elevated temperature. The drying temperature for the metal electrode should be lower than the melting or
carbonization point of the substrate used, but higher than the curing temperature of
the metal ink. The drying temperature of metal ink can vary depending on the
identity of the substrate and can be in the range of about 120 °C to about 250 °C. In
one embodiment, the drying temperature is between about 150 °C to about 240 °C.
In another embodiment, the drying temperature is between about 180 °C to about
220 °C. For example, the drying temperature of Ag ink printed onto a PET substrate
can be in the range of about 180 °C to about 220 °C.

[0025] The active material can comprise a carbon nanostructure, a metal oxide,
or a combination thereof. As defined herein, the term "active material" is a material
capable of storing a charge (e.g., electrical) inside or on the surface of the material.
The active material can also comprise a combination of one or more carbon
nanostructures and one or more metal oxides. In one embodiment, the active
material comprises a carbon nanostructure and a metal oxide. In another
embodiment, the active material comprises carbon nanotubes and manganese oxide
(MnO2). In yet another embodiment, the active material comprises onion-like
carbon and manganese oxide (MnO2). In another embodiment, the active material
comprises graphene and manganese oxide (MnO2).

[0026] The metal oxide of the present invention is not limited to manganese
oxide (MnO2). Other metal oxides of the invention include, but are not limited to,
manganese oxide (MnO2), ruthenium oxide (RuO2), nickel oxide (NiO), cobalt oxide
(e.g., CoO, Co2O3, Co3O4), copper oxide (CuO), vanadium oxide (e.g., V2O5, V2O3,
VO2, VO), iron-manganese oxide (e.g., Fe2O3, Fe3O4) iron-manganese oxide, iron-
nickel oxide, iron-copper oxide, cobalt-manganese oxide, manganese-titanium
oxide, or a combination thereof. In one embodiment, the metal oxide is MnO2. The
metal oxide of the invention should have the ability to transport electrons and to
support high capacitance and high power density.

[0027] "Carbon nanostructure," as the term is used herein, is defined as any
carbon form with at least one dimension on the order of 1 μm or less. Examples of
carbon nanostructures include, but are not limited to, onion-like carbon, carbon
nanotubes (e.g., carbon single-wall nanotubes, multi-wall nanotubes), nanohorns,
nanowires, nanofoam, nanoribbon, buckytubes, carbon fibers, activated carbon
(including extruded activated carbon), conductive carbon black, oriented pyrolytic graphite; carbon aerogels; and various forms of graphene.

[0028] The carbon nanostructure in the present invention describes the material, and is not restricted by the methods used to prepare the material. Carbon nanostructures can be directly grown on a metal substrate using thermal chemical deposition, microwave plasma chemical deposition, arc-discharge, or laser vaporization synthesis, for example. The synthesis conditions (e.g., temperature, pressure, carrier gas, etc.), metal catalyst type (for carbon nucleation), and carbon source (e.g., graphite or hydrocarbon) are all known to influence the properties of the resulting carbon nanostructures. Various carbon sources can also be utilized to grow carbon nanotubes. Examples of carbon sources that may be used to grow carbon nanotubes include, but are not limited to, alkanes, alkenes, alkynes, polymers, carbon oxides, and combinations thereof. Additional carbon sources for growing carbon nanotubes are envisioned.

[0029] Carbon nanotubes are generally categorized as single-wall carbon nanotubes (SWNT) and multi-wall carbon nanotubes (MWNT). Single-wall carbon nanotubes are fullerenes consisting essentially of sp²-hybridized carbon typically arranged in hexagons and pentagons. These carbon cylindrical structures, known also as "buckytubes," have extraordinary properties, including high electrical, thermal conductivity, high strength and stiffness. Multi-wall carbon nanotubes are nested single-wall carbon cylinders and possess some properties similar to single-wall carbon nanotubes.

[0030] Single-wall carbon nanotubes and multi-wall carbon nanotubes can be made by any known means, such as by gas-phase synthesis from high temperature, high-pressure carbon monoxide, catalytic vapor deposition using carbon-containing feedstocks and metal catalyst particles, laser ablation, an arc-discharge method, or any other method for synthesizing single-wall and multi-wall carbon nanotubes.

[0031] Onion-like carbon is referred to by various names (e.g., carbon onion, bucky onion, onion-like fullerene, and onion-like graphite) and is a kind of giant fullerene. It has a structure in which around the perimeter of the core, at the central portion comprising C₆₀, or the like, it has fullerenes each having a still larger
molecular weight concentrically stacked one on another. Onion-like carbon can be made by any known method. For example, carbonization of phenolic-formaldehyde resin at 1000 °C with the aid of ferric nitrate, or alternatively, pyrolysis of carbon black at 1000 °C can provide onion-like carbon.

[0032] The active material can further comprise a binder. The active material is mixed with the binder to form a slurry that can then be screen printed or applied to the metal electrodes. As used herein, a "binder" refers to a material that can be used to bind components of a mixture together. The binder can be a polymer or a copolymer. As used herein, the term "polymer" refers to a macromolecule made of repeating monomer units. The term "copolymer" is defined as a polymer of at least two chemically distinct monomers. The copolymers of the invention include, but are not limited to, alternating copolymers, statistical copolymers, block copolymers, random copolymer, and graft copolymers. In one embodiment, the binder is a polymer comprising at least one monomer. In another embodiment, the binder is a copolymer comprising one or more monomers.

[0033] In one embodiment, the binder is a polymer or a copolymer. The monomers that can be used to synthesize the binder polymers or copolymers of the present invention include, but are not limited to, vinylidene fluoride, trifluoroethylene, chlorotrifluoroethylene, tetrafluoroethylene, hexafluoropropylene, 1,1-chlorofluoroethylene, poly(methyl methacrylate), 11-aminoundecanoic acid, and thiourea, or a combination thereof. The binder polymers of the present invention can be a copolymer comprising two or more monomers.

[0034] The ratio of one monomer to another monomer or monomers used to synthesize the copolymers can vary depending on the properties desired. The ratio of one monomer to another monomer can be between about 60:40 to about 95:5. In one embodiment, the binder is polyvinyl difluoride (PVDF). In another embodiment, the binder is poly(vinylidene fluoride-co-trifluoroethylene) (P(VDF-TrFE)). The binder can also be a blend of two or more polymers or copolymers. The binder can be present in an amount of about 40 wt% to about 5 wt% of the active material mixture, preferably about 20 wt%, more preferably about 10 wt%.
The electrolyte can be solid or liquid, although solid electrolytes are preferred. When the electrolyte is a solid, it may be chemically bonded or physically adsorbed with the metal oxide and/or the carbon nanostructures, or it may form a distinct phase within the structure. Various solid electrolytes are suitable for use in the MSC of the present invention. Examples of solid electrolytes include; but are not limited to, polyvinyl alcohol (PVA)/phosphoric acid (H₃PO₄), PVA/sulfuric acid (H₂SO₄), PVA/potassium hydroxide (KOH), PVA/sodium hydroxide (NaOH), or a combination thereof. In one embodiment, the solid electrolyte is polyvinyl alcohol (PVA)/phosphoric acid (H₃PO₄).

Liquid electrolytes in micro supercapacitors may be aqueous or organic. Examples of aqueous liquid electrolytes include, but are not limited to, sodium sulfate, potassium sulfate, sulfuric acid, potassium hydroxide, and sodium hydroxide. Examples of organic electrolytes include, but are not limited to, tetraalkyammonium salts, ethylene carbonate, propylene carbonate, propanediol-1, 2-carbonate, dichloroethylene carbonate, polyurethane, lithium trifluoromethanesulfonate (LiCF₃SO₂), polyurethane-lithium perchlorate, poly(acrylonitrile)-lithium salts, and poly (acrylonitrile)-quaternary ammonium salts.

The present invention also relates to a method of making a micro supercapacitor, comprising: a) screen printing a metal ink on a substrate to form a first metal electrode and a second metal electrode; b) drying the first metal electrode and the second metal electrode under vacuum and elevated temperature; c) screen printing an active material ink on top of the first metal electrode and the second metal electrode to form an active material on the first and second metal electrode; d) drying the active material on the first and second metal electrode at an elevated temperature; and e) drop-casting a solid electrolyte onto the active material on the first and second metal electrode to form the micro supercapacitor. The method is suitable for making CNT-MSCs as well as MSCs containing other active materials such as carbon nanostructures, metal oxides, carbon/metal-oxides, and combinations thereof.
A schematic diagram of the all solid micro supercapacitor (e.g., CNT-MSC) is shown in FIG. 1(a). The basic structure of the MSC is composed of two electrodes 1 (positive and negative electrodes), active material 3 on top of the electrodes and the electrolyte 2. In order to increase the electrode area, the electrodes are patterned into an interdigital shape. The ions 10 transfer the charges between the two electrodes to run the charge/discharge process indicated by the arrows in FIG 1(a).

A schematic diagram of the micro supercapacitor (e.g., CNT-MSC) fabrication process is shown in FIG. 1(b). The metal (e.g., Ag) electrodes 1 can be screen printed directly on the bare substrate 4 (e.g., PET) as show in FIG. 1. Screen printing of the metal electrode uses a mesh screen to receive or produce a desired image or pattern. The openings in the mesh screen allow the transferring of ink or other printable materials which can then be pressed through the mesh as a sharp-edged image onto a substrate. The screen is attached to a support (e.g., a substrate) and the pattern is formed on the screen. A brush is used to push the ink through the openings of the mesh screen onto the substrate. After printing, the screen/mesh is removed. The mesh screen 5 can be made of various materials and the openings of the mesh screen can also vary in size.

During the printing process, a mesh screen 5 possessing a pattern is placed on top of the substrate 4 (step 1, FIG. 1(b)) and the ink (e.g., Ag ink) is pressed through the openings of the mesh screen 5 using a brush 6 (step 2, FIG. 1(b)). The screen 5 is then removed to provide the patterned electrode (e.g., interdigital pattern, metal pattern) on the substrate 4. Once the metal electrodes are dried, the active material ink can be screen printed (3 in FIG. 1) onto the electrodes and dried to form a CNT metal electrode using the same printing process used for making the metal electrodes 1 (step 4, FIG. 1(b)) to produce the MSC circuit 9. An active material ink can be prepared, for example, by mixing 80 wt% CNT, 10 wt% conductive carbon black and 10 wt% polyvinylidifluoride (PVDF) binder in N-methylpyrroldione (NMP) using an agate mortar (see FIG. 1).

The micro supercapacitor can be tested in either a solid or liquid electrolyte. When the MSC is tested in a solid electrolyte, an electrolyte 2 can be
drop-cast onto the dried active material on the first and second metal electrodes (e.g., MnCVOLC-Ag electrode) and then allowed to solidify overnight to form the solid electrolyte and complete the fabrication of the all solid micro supercapacitor.

The drying of the first and second electrode and the active material can be done at a temperature between about 100°C to about 250°C for between about 1 h to about 48 h. The drying of the first and second electrode and the active material can also be done under both reduced pressure (e.g., vacuum) and at elevated temperatures. The optimal conditions for the drying of the metal electrode and the drying of the active material will depend on the identity of the metal and active material being used to fabricate the MSC. For example, an Ag electrode can be dried under vacuum (e.g., in a vacuum oven) at temperature of about 200°C for about 2 h. A manganese oxide/onion-like (MnCVOLC) active material can be dried at a temperature of about 110°C for about 10 h. The drying conditions may also vary between active materials made by different fabrication processes.

The electrochemical properties of solution based MSCs were studied using a typical three-electrode configuration in 6 M aqueous KOH at room temperature. A saturated calomel electrode (SCE) was selected as the reference electrode. For solid MSCs, the electrochemical properties were investigated at room temperature using a typical two electrode configuration with polyvinyl alcohol/phosphoric acid (PVA/H₃PO₄) as the solid electrolyte.

FIG. 2(a) is a photograph of a carbon nanotubes micro supercapacitor (CNT-MSC) held by a researcher showing the flexible properties of the MSCs. FIG. 2(b) and (c) show the scanning electron microscope (SEM) images of carbon nanotubes (CNT) on a silver (Ag) electrode or current collector. The Ag electrodes and the CNTs can be patterned to form a network shape as depicted in FIG. 2(c) which facilitates the complete immersion of the electrolyte into the CNT-MSC resulting in higher energy storage.

The electrochemical characteristics of a carbon nanotubes micro supercapacitor (CNT-MSC) were performed in KOH electrolyte and included charging/discharging curves under different current densities and CV tests at varied scan rates. The results are shown in FIG. 3. The Ag electrode can act as the current
collector and the CNT can act as the active material. The specific capacitance and power of a CNT-MSC can reach up to about 40 mF/cm² and about 0.928 mW/cm², respectively, at a current density of about 4 mA/cm². The capacity for a CNT-MSC can also be maintained at about 87.5% after about 1000 time cycles. The specific capacitance of a CNT-MSC was shown to be much higher than that of CNT forest MSCs and activated carbon MSCs [17, 24]. These results confirm that screen printed MSCs can store and release energy. The flexible electronic MSC devices of the present invention provide energy storage devices allow energy storage without a heavy or bulky MSC structure.

[0046] The solid MSCs as compared to the solution based MSCs (e.g., containing liquid electrolytes) can be bent into any shape without electrolyte leakage. From the point of fabrication, solid flexible MSCs can be easier and cheaper than the solution-based MSCs to prepare but both solid and solution-based MSCs are accessible and provide energy storage.

[0047] FIG. 4(a) shows a photograph of a solid flexible CNT-MSC. The electrochemical characterizations in FIGs. 4(b) to 4(c) show that the capacitance of a solid flexible CNT-MSC can reach up to about 3.5 mF/cm² at a current density of about 83 µA/cm². The performance of the solid flexible CNT-MSCs can be further improved by optimizing the fabrication parameters or employing other active materials.

[0048] In another aspect, the present invention also relates to an active material, comprising manganese oxide (MnO₂) grown on the surface of onion-like carbon (OLC) to form a MnO₂/OLC nanocomposite. The manganese oxide (MnO₂) grown on the surface of onion-like carbon forms a nanocomposite. The nanocomposite exhibits a flower-like structure composed of manganese oxide (MnO₂) nanoribbons radiating from the onion-like carbon center of the nanocomposite. The MnO₂ can be made by various methods. For example, one method that can be used to make the MnO₂/OLC nanocomposite is the hydrothermal method described in Example 2.

[0049] The onion-like carbon can be synthesized by various methods and can have a diameter between about 5 nm and about 80 nm, preferably between about 10 nm and about 60 nm, more preferably between about 15 nm and about 40 nm. Once
the manganese oxide (MnO₂) is deposited on the surface of onion-like carbon the resulting nanocomposite can have a diameter between about 50 nm and about 400 nm, preferably between about 100 nm and about 300 nm, more preferably between about 200 nm and about 300 nm.

[0050] The interplanar spacing and length of MnO₂ nanoribbons can vary. The interplanar spacing of the MnO₂ nanoribbons is determined by the precursor and synthesis method used. In one embodiment, the interplanar spacing of the MnO₂ nanoribbons is between about 0.67 nm to about 0.72 nm. The length of MnO₂ nanoribbons can be anywhere between about 10 nm to about 300 nm, preferably about between about 20 nm to about 250 nm, more preferably between about 30 nm to about 200 nm, most preferably between about 100 nm and about 150 nm. In one embodiment, the length of MnO₂ nanoribbons is about 120 nm for MnO₂/OLC nanocomposite.

[0051] The morphologies of MnO₂/OLC nanocomposite are shown in FIG. 5(a) and FIG. 5(b) at scale bars of 1 μm and 200 nm, respectively. The diameter of the pure OLC of MnO₂/OLC shown in FIG. 5 was determined to be between about 20 nm to about 30 nm, while the diameter of MnO₂/OLC nanocomposite in FIG. 5 was found to be in the range of about 200 nm to about 300 nm. The MnO₂/OLC nanocomposite exhibit a flower like structure composed of MnO₂ nanoribbons radiating from the centre. The morphology of the nanocomposite were found to be similar to that of nanoflakes grown from CNT [28]. A proposed growth mechanism is shown in FIG. 5(c).

[0052] The OLC was fully immersed in a KMnO₄ solution at low temperature (about 45 °C to about 55 °C) and the solution was then heated by a hydrothermal process to produce the final MnO₂/OLC nanocomposite. When the solution was heated, MnO₂ nanocrystals/seeds grew on the surface of the OLC. This growth is believed to have occurred due to the slow reaction between KMnO₄, the onion-like carbon and water as depicted in equation 1 (eqn 1). The MnO₂ nanoribbons are believed to have grown from the nanocrystals/seeds on the surface of the OLC as the mixture was heated [28].
4MnO$_4^-$ + 3C + H$_2$O $\rightarrow$ 4KMnO$_4$ + CO$_2$ + 2HCO$_3^-$ (eqn 1)
4MnO$_4$ + H$_2$O $\rightarrow$ 4MnO$_2$ + 4OH$^-$ + 2O$_2$ (eqn 2)

[0053] It is known that KMnO$_4$ decomposes in water (eqn. 2). It is believed that this decomposition is what can lead to the flower-like shape of the MnO$_2$ observed on the surface of OLC. The TEM image of the nanoribbons shown in FIG. 6(a) revealed that the interplanar spacing of MnO$_4$ nanoribbons is about 0.7 nm. The length of MnO$_2$ nanoribbons was estimated to be about 100 nm for MnO$_2$/OLC nanocomposite. The nanocomposite product obtained appeared to possess a birnessite-type MnO$_2$, which has interlayer water and potassium doping. The EDX spectroscopy results shown in FIG. 6(b) indicated that the K/Mn ratio is about 0.23.

[0054] FIG. 7(a) show photographs of solid flexible MnO$_2$/OLC- MSCs. The electrochemical characterizations of one solid flexible MnO$_2$/OLC- MSC in FIG. 7(a) are shown in FIGs. 7(b) to 7(d). The capacitance of the MnO$_2$/OLC-MSCs in FIG. 7(a) can reach up to about 3.8 mF/cm$^2$ under a current density of about 0.02 mA/cm$^2$. The device performance can be further improved by optimizing the fabrication conditions, employing other active materials, and the varying the MSC dimensions.

EXAMPLES

Example 1: Preparation of onion-like carbon

[0055] Ethanol, Ferric nitrate (FN) and phenolic formaldehyde resin (PF) (in a molar ratio of 1:16 FN: PF) were placed in a flask and the resulting mixture was stirred until a homogeneous solution was formed. The solvent was then removed under vacuum to obtain a solid [29]. Hexamethylenetetramine (14 wt%) and acetone were added to the resulting solid and the resulting mixture was subjected to ultrasonic vibration for 20 minutes. The mixture was then heated in an oven at about 60°C to remove the acetone, and then the temperature was increased to about 150°C to produce a cross-linked structure. Carbonization of the resulting cross-linked structure was accomplished by heating the cross-linked structure to about 1000 °C for about 10 h under an atmosphere of nitrogen to obtain the carbon/iron composite. The iron was removed by treating the carbon/iron composite with 37 wt% hydrochloric acid (HCl) for about 48 hours to obtain the desired product. The
resulting product was washed with distilled water until the pH of the filtrate was approximately 1 or neutral.

**Example 2: Preparation of Manganese Oxide (MnO)₂/ Onion-like Carbon Nanocomposite**

[0056] 150 mg of potassium permanganate (KMnO₄) was dissolved in 25 ml deionized (DI) water. 50 mg of onion-like carbon (OLC) was then added and the resulting mixture was stirred at about 55°C for about 6 hours. The mixture was transferred to a 50 ml Teflon-lined stainless steel autoclave, sealed and heated in an oven at about 150°C for 12 hours. After 12 hours, the resulting mixture was cooled to room temperature and the desired product was isolated as a solid by centrifugation. The product was then washed several times with deionized water and dried at 100°C overnight.

[0057] Morphologies of the nanocomposites were examined by field emission scanning electron microscopy (FESEM) and transmission electron microscopy (TEM). Compositional investigation of nanocomposites was carried out with energy-dispersive X-ray (EDX).

**Example 3: Preparation of the manganese oxide/onion-like carbon active material ink**

[0058] 80 wt% MnO₂/OLC, 10 wt% conductive carbon black and 10 wt% polyvinylidifluoride (PVDF) binder in N-Methylpyrroliodine (NMP) were placed in an agate mortar and mixed until a slurry was formed. The slurry can then be used as the active material ink in the fabrication of the micro supercapacitor.

**Example 4: Preparation of the Electrolyte Solution**

[0059] 3 g of polyvinyl alcohol (PVA), 3 g phosphoric acid (H₃PO₄) and 30 ml deionized water (DI) water were placed in a flask and heated to about 85°C for 2 hours to form a clear solution. The resulting solution was used to form the solid electrolyte.

**Example 5: Preparation of the Micro Supercapacitor**

[0060] Silver (Ag) electrodes (current collector) were screen printed directly on a polyethylene terephthalate (PET) substrate using silver metal ink and dried in a
vacuum for 2 hours at temperature of about 200 °C. The manganese oxide/onion-like active material ink was then screen printed onto the Ag electrode and dried in a vacuum oven at about 110°C for 10 h. Once dried, the electrolyte solution was drop-cast onto manganese oxide/onion-like Ag electrode and then allowed to solidify overnight to form the solid electrolyte and complete the fabrication of the micro supercapacitor.

Example 6: Electrochemical Characterization of the MSCs

The MSCs were characterized to determine their capacitance, voltage window, and other parameters.

The galvanostatic charge/discharge test was performed using a voltage range of 0 to 1 volt and at varying current densities of about 0.02 milliampere per square centimeter (mA cm⁻²) to 0.2 mA cm⁻² on a Newware battery tester (Shenzhen, China). The values of specific capacitance reported herein were measured using cyclic Voltammetry (CV). CV was carried out using an electrochemical workstation VMP3, manufactured by Bio-Logic, France. CV measurements were carried out at different scan rates. The electrochemical characterization results for the CNT-MSC can be found in FIG. 3, for the solid flexible CNT-MSC can be found in FIG. 4, and for the solid flexible Mn⁴⁺/OLC-MSC can be found in FIG. 7.

REFERENCES

[0063] The term "about" generally refers to a range of numbers that one of skill in the art would consider equivalent to the recited value (i.e., having the same function or result). In some versions the term "about" refers to ±10% of the stated value, in other versions the term "about" refers to ±2% of the stated value.

[0064] The teachings of all patents, published applications and references cited herein are incorporated by reference in their entirety.

[0065] While this invention has been particularly shown and described with references to example embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the scope of the invention encompassed by the appended claims.
CLAIMS

What is claimed is:

1. A micro supercapacitor, comprising:
   a substrate;
   a first metal electrode;
   a second metal electrode;
   an active material coating the first metal electrode and the second metal electrode, comprising manganese oxide (MnO₂), carbon nanostructures and optionally a binder; and
   an electrolyte,
   wherein the first metal electrode and the second metal electrode are located in the same plane on the substrate.

2. The micro supercapacitor of claim 1, wherein the carbon nanostructure comprises onion like carbon, carbon nanotubes, conductive carbon black, or a combination thereof.

3. The micro supercapacitor of claim 1, wherein the substrate is flexible.

4. The micro supercapacitor of claim 1, wherein the substrate comprises polyethylene terephthalate (PET), polyethylene naphthalate (PEN), polycarbonate (PC), polyethersulfone (PES), photographic paper, insulated thermal tape, or a combination thereof.

5. The micro supercapacitor of claim 1, wherein the metal electrode comprises a metal selected from silver (Ag), gold (Au), copper (Cu), aluminum (Al), platinum (Pt), or a combination or alloys thereof.

6. The micro supercapacitor of claim 1, wherein the electrolyte comprises a solid electrolyte.
7. The micro supercapacitor of claim 1, wherein the binder is a polymer or copolymer comprising vinylidene fluoride, trifluoroethylene, chlorotrifluoroethylene, tetrafluoroethylene, hexafluoropropylene, 1,1-chlorofluoroethylene, poly(methyl methacrylate), 11-aminoundecanoic acid, thiourea, or a combination thereof.

8. The micro supercapacitor of claim 1, wherein the active material comprises manganese oxide (MnO₂) deposited on the surface of onion-like carbon.

9. The micro supercapacitor of claim 1, wherein the active material comprises manganese oxide (MnO₂) and carbon nanotubes.

10. The micro supercapacitor of claim 1, wherein the first metal electrode and the second metal electrode are patterned.

11. The micro supercapacitor of claim 10, wherein the first metal electrode and the second metal electrode are patterned to create channels between the first metal electrode and the second metal electrode.

12. The micro supercapacitor of claim 11, wherein the channel width is less than about 1 mm.

13. A method of making a micro supercapacitor, comprising
   a) screen printing a metal ink on a substrate to form a first metal electrode and a second metal electrode;
   b) drying the first metal electrode and the second metal electrode under vacuum and elevated temperature;
   c) screen printing an active material ink on top of the first metal electrode and the second metal electrode to form an active material on the first and second metal electrode;
   d) drying the active material on the first and second metal electrode at an elevated temperature; and
   e) drop-casting a solid electrolyte onto the active material on the first and second metal electrode to form the micro supercapacitor.
14. The method of claim 13, wherein the active material comprises a carbon nanostructure, a metal oxide, or combination thereof.

15. The method of claim 13, wherein the active material comprises manganese oxide (MnO₂) and carbon nanotubes.

16. The method of claim 13, wherein the active material comprises manganese oxide (MnO₂) and onion-like carbon.

17. The method of claim 13, wherein the active material comprises manganese oxide (MnO₂) and graphene.

18. The method of claim 13, wherein the first metal electrode and the second metal electrode are patterned to create channels between the first metal electrode and the second metal electrode.

19. An active material, comprising:
   manganese oxide (MnO₂) grown on the surface of onion-like carbon.

20. The active material of claim 19, wherein the onion-like carbon has a diameter between about 15 nm and about 40 nm.

21. The active material of claim 19, wherein the manganese oxide (MnO₂) grown on the surface of onion-like carbon forms a nanocomposite having a diameter between about 50 nm and about 400 nm.

22. The active material of claim 19, wherein the nanocomposite exhibits a flower-like structure composed of manganese oxide (MnO₂) nanoribbons radiating from the onion-like carbon center of the nanocomposite.

INTERNATIONAL SEARCH REPORT

international application No. PCT/SG2013/000444

A. CLASSIFICATION OF SUBJECT MATTER

H01G 11/34 (2013.01)

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and where practicable, search terms used)

Group 1: WPI, EPDOC, INSPEC: micro supercapacitor, electrode, substrate, active material, electrolyte, metal and similar terms Google, Google Scholar, Google Patents: interdigital supercapacitor electrolyte substrate

Group 2: WPT, EPDOC, INSPEC: micro supercapacitor, electrode, screen printing, ink and similar terms Google, Google Scholar, Google Patents: "screen printing" "metal ink" method substrate; Common examples of solvent-based coating techniques include drop casting, spin-coating, doctor-blading, inkjet printing and screen printing

C. DOCUMENTS CONSIDERED TO BE RELEVANT

[S]: Special categories of cited documents

[A]: document defining the general state of the art which is not considered to be of particular relevance

[E]: earlier application or patent but published on or after the international filing date

[L]: document which may throw doubts on priority claims of which it is cited to establish the publication date of another citation or other special reason (as specified)

[O]: document referring to an oral disclosure, use, exhibition or other means

[P]: document published prior to the international filing date but later than the priority date claimed

[I]: later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

[N]: document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

[Y]: document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is taken in combination with one or more other such documents, such combination being obvious to a person skilled in the art

&: document member of the same patent family

Form PCT/IP/A/210 (fifth sheet) (My 2009)
**INTERNATIONAL SEARCH REPORT**

**Box No. I**  
Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [ ] Claims Nos.:  
   because they relate to subject matter not required to be searched by this Authority, namely:
   the subject matter listed in Rule 39 on which, under Article 17(2)(a)(i), an international search is not required to be earned out, including

2. [ ] Claims Nos.:  
   because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. [ ] Claims Nos.:  
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a)

**Box No. II**  
Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

**See Supplemental Box for Details**

1. [ ] As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. [ ] As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.

3. [x] As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.: 1-18

4. [ ] No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**

[ ] The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

[ ] The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

[ ] No protest accompanied the payment of additional search fees.

Continuation of: Box 111

This International Application does not comply with the requirements of unity of invention because it does not relate to one invention or to a group of inventions so linked as to form a single general inventive concept.

This Authority has found that there are different inventions based on the following features that separate the claims into distinct groups:

- Claims 1-12 are directed to a micro supercapacitor. The feature of the first metal electrode and the second metal electrode are located in the same plane on the substrate is specific to this group of claims.

- Claims 13-18 are directed to a method for making a micro supercapacitor. The feature of screen printing the electrodes and drop-casting a solid electrolyte onto the active material on the first and second electrodes to form the micro supercapacitor is specific to this group of claims.

- Claims 1-10 are directed to an active material. The feature of the active material being manganese dioxide grown on the surface of onion-like carbon is specific to this group of claims.

PCT Rule 13.2, first sentence, states that unity of invention is only fulfilled when there is a technical relationship among the claimed inventions involving one or more of the same or corresponding special technical features. PCT Rule 13.2, second sentence, defines a special technical feature as a feature which makes a contribution over the prior art.

When there is no special technical feature common to all the claimed inventions there is no unity of invention.

In the above groups of claims, the identified features may have the potential to make a contribution over the prior art but are not common to all the claimed inventions and therefore cannot provide the required technical relationship. Therefore there is no special technical feature common to all the claimed inventions and the requirements for unity of invention are consequently not satisfied a priori.
This Annex lists known patent family members relating to the patent documents cited in the above-mentioned international search report. The Australian Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
