(54) **Title: AN ELECTRICALLY HEATED SMOKING SYSTEM WITH IMPROVED HEATER**

(57) **Abrégé/Abstract:**

There is provided an electrically heated smoking system for receiving an aerosol-forming substrate. The system comprises at least one heater for heating the aerosol-forming substrate to form the aerosol, and a power supply for supplying power to the at least one heater. The at least one heater comprises one or more electrically conductive tracks on an electrically insulating substrate. In one arrangement, the one or more electrically conductive tracks have temperature coefficient of resistance characteristics such that the one or more electrically conductive tracks can act as resistive heaters and as a temperature sensor. In another arrangement, the electrically heated smoking system further comprises a thermally insulating material for insulating the at least one heater from the outside of the electrically heated smoking system.

ABSTRACT

There is provided an electrically heated smoking system for receiving an aerosol-forming substrate. The system comprises at least one heater for heating the aerosol-forming substrate to form the aerosol, and a power supply for supplying power to the at least one heater. The at least one heater comprises one or more electrically conductive tracks on an electrically insulating substrate. In one arrangement, the one or more electrically conductive tracks have temperature coefficient of resistance characteristics such that the one or more electrically conductive tracks can act as resistive heaters and as a temperature sensor. In another arrangement, the electrically heated smoking system further comprises a thermally insulating material for insulating the at least one heater from the outside of the electrically heated smoking system.

AN ELECTRICALLY HEATED SMOKING SYSTEM WITH IMPROVED HEATER

This application is a division of Canadian Patent Application No. 2778903 filed October 28, 2010.

The present invention relates to an electrically heated smoking system including a heater for heating an aerosol-forming substrate.

US-A-5 353 813, discloses a bladed tubular array for use as an external heating element in an electrical smoking article. The heating element comprises a number of carbon blades arranged around a reinforcing tube of spiral wound paper board. One electrical connection is formed at a free end of the blades, while a common ring of carbon connects the other end of the carbon blades to form a common electrical connection. When the blades are powered, they heat to provided a heating zone with a temperature in the range of 300 °C to about 900 °C.

The inventors have appreciated that it would be advantageous to provide an electrically heated smoking system which is easier to manufacture and also requires fewer components in its construction.

According to a first aspect of the invention, there is provided an electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising: at least one heater for heating the substrate to form the aerosol, and a power supply for supplying power to the at least one heater, wherein the at least one heater comprises one or more electrically conductive tracks on an electrically insulating substrate, the one or more electrically conductive tracks having temperature coefficient of resistance characteristics such that the one or more electrically conductive tracks can act as both a resistive heater and as a temperature sensor.

According to the first aspect of the invention, there is also provided a heater for use in an electrically heated smoking system, the heater comprising one or more electrically conductive tracks on an electrically insulating substrate.

According to the first aspect of the invention, there is also provided use of a heater in an electrically heated smoking system, the heater comprising one or more electrically conductive tracks on an electrically insulating substrate, the one or more electrically conductive tracks having temperature coefficient of resistance characteristics such that the one or more electrically conductive tracks can act as both a resistive heater and as a temperature sensor.

By using a heater comprising electrically conductive tracks on an electrically insulating substrate, which can act as both a heater and as a temperature sensor, the number and size of components required in the electrically heated smoking system can be reduced. This allows the size of the electrically heated smoking system to be reduced. In addition, the electrically insulating substrate can be very thin, allowing further size reduction. In addition, some or all of the necessary electronics, wiring and connections may be incorporated on the same electrically insulating

substrate as the heater. In addition, the heater may be manufactured more straightforwardly and cost effectively than some prior art heaters which require each heating element to be individually formed. The heater allows a great deal of flexibility in the design: the electrically conductive tracks can be arranged on the electrically insulating substrate as desired and in order to give the desired heat distribution.

Preferably, the electrically heated smoking system further comprises electronic circuitry arranged to control supply of power from the power supply to the at least one heater.

Preferably, the power supply supplies power to the at least one heater in dependence upon the temperature sensed by the one or more electrically conductive tracks and a desired temperature. That is to say, feedback is provided which allows the power supply to maintain the heater, and the aerosol-forming substrate, at a particular desired temperature. This is achieved without the need for a separate temperature sensor. Preferably, the electrically heated smoking system includes electronic circuitry arranged for this purpose. Preferably, the desired temperature is a temperature at which the heater heats, but does not burn, the aerosol-forming substrate.

Preferably, the electrically heated smoking system further comprises a thermally insulating material for insulating the at least one heater. The thermally insulating material may insulate the material from the outside of the electrically heated smoking system. Preferably, the heater comprises a portion of electrically insulating substrate which has a thermally insulating or/and reflective structure thereon.

According to a second aspect of the invention, there is provided an electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising: at least one heater for heating the substrate to form the aerosol, the at least one heater comprising one or more electrically conductive tracks on an electrically insulating substrate; a power supply for supplying power to the at least one heater; and a thermally insulating material for insulating the at least one heater.

According to the second aspect of the invention, there is also provided a thermally insulating material for use in an electrically heated smoking system having a heater comprising one or more electrically conductive tracks on an electrically insulating substrate.

According to the second aspect of the invention, there is also provided use of a thermally insulating material in an electrically heated smoking system having a heater comprising one or more electrically conductive tracks on an electrically insulating substrate.

The thermally insulating material reduces heat loss from the heater and also protects a user using the electrically heated smoking system from burning. The thermally insulating material is preferably positioned around the aerosol forming substrate so as to provide the greatest thermal

insulation. The thermally insulating material must be a material which will not degrade in the high temperatures reached in the electrically heated smoking system. Not all thermally insulating materials will be suitable. Preferably, the thermally insulating material comprises a metal or another non-combustible material. In one example, the metal is gold. In another example, the metal is silver. A metal is advantageous as it may reflect heat back into the electrically heated smoking system.

Preferably, the thermally insulating material comprises a plurality of air cavities. The air cavities are arranged in a regular pattern. In one preferred embodiment, the air cavities are hexagonal and arranged in a honeycomb structure. The thermally insulating material may be provided on the electrically insulating substrate in addition to the electrically conductive tracks. This allows the electrically conductive tracks and thermally insulating material to be manufactured as one element. For some methods of manufacture, the electrically conductive tracks and the thermally insulating material may be made as part of the same process. Alternatively, the thermally insulating material may be provided in the electrically heated smoking system as a separate element.

As in the first aspect of the invention, the electrically insulating substrate can be very thin, allowing size reduction. In addition, some or all of the necessary electronics, wiring and connections may be incorporated on the same electrically insulating substrate as the heater. In addition, the heater may be manufactured more straightforwardly and cost effectively than some prior art heaters which require each heating element to be individually formed. The heater allows a great deal of flexibility in the design: the electrically conductive tracks can be straightforwardly arranged on the electrically insulating substrate as desired and in order to give the desired heat distribution.

Preferably, the electrically heated smoking system further comprises electronic circuitry arranged to control supply of power from the power supply to the at least one heater.

Preferably, the power supply supplies power to the at least one heater in dependence upon a desired temperature. Preferably, the electrically heated smoking system includes electronic circuitry arranged for this purpose. Preferably, the desired temperature is a temperature at which the heater heats, but does not burn, the aerosol-forming substrate.

Preferably, the one or more electrically conductive tracks have temperature coefficient of resistance characteristics such that the one or more electrically conductive tracks can act as resistive heaters and as a temperature sensor.

In one embodiment of either aspect of the invention, the one or more electrically conductive tracks comprise a plurality of portions, each portion being separately connectable to the power

supply. This provides a number of advantages. First, it allows the different portions to be heated for different durations, which may enhance the smoking experience, depending on the nature of the aerosol-forming substrate. Second, it allows the different portions to be heated at different temperatures, which may also enhance the smoking experience, depending on the nature of the aerosol-forming substrate. Third, it allows a particular portion of the heater to be activated at any one time. This allows only a portion of the aerosol-forming substrate to be heated at any one time. This may be advantageous as it means that each portion of the aerosol-forming substrate may be heated only once, and not reheated.

In one embodiment of either aspect of the invention, the electrically conductive track or tracks comprise a single track of electrically conductive material. A first end of the single track is connectable to the power supply and a second end of the single track is connectable to the power supply. In that case, the power supply may also be connectable to one or more central sections of the single track to provide a plurality of portions, each portion being separately connectable to the power supply. In another embodiment of either aspect of the invention, the electrically conductive track or tracks comprise a plurality of tracks of electrically conductive material, each track being separately connectable to the power supply.

In both aspects of the invention, the electrically conductive tracks are arranged on the electrically insulating substrate in a formation most suitable to heat the aerosol-forming substrate. Any number of configurations is possible.

In a first embodiment of either aspect of the invention, the electrically insulating substrate is rigid and is arranged to be inserted into the aerosol-forming substrate. If the electrically insulating substrate is appropriately sized and is rigid, it may be inserted directly into the aerosol-forming substrate. The electrically insulating substrate may be reinforced in some way in order to provide sufficient rigidity. In that case, if a thermally insulating material is provided, it may be provided to surround the aerosol-forming substrate.

In a second embodiment of either aspect of the invention, the electrically insulating substrate is tubular and the one or more electrically conductive tracks are on the inside of the tubular electrically insulating substrate. Such an arrangement may be used as an external heater. The external heater may be used to surround or partially surround the aerosol-forming substrate. In one embodiment, the aerosol-forming substrate is solid and is in the form of a cylindrical plug. In that case, preferably the internal diameter of the external heater is the same as or slightly bigger than the external diameter of the aerosol-forming plug. In the second embodiment, if a thermally insulating material is provided, it may be provided to surround the aerosol-forming substrate and external heater. The thermally insulating material may be provided on the electrically insulating

substrate and the external heater may be formed by rolling the electrically insulating substrate so that the electrically conductive tracks are towards the inside of the tube and the thermally insulating material is towards the outside of the tube.

In a third embodiment of either aspect of the invention, the electrically insulating substrate is tubular and the one or more electrically conductive tracks are on the outside of the tubular electrically insulating substrate. Such an arrangement may be used as an internal heater. The internal heater may be inserted into the aerosol-forming substrate. In one embodiment, the aerosol-forming substrate is solid and comprises a hollow tube of aerosol-forming substrate. In that case, preferably the external diameter of the internal heater is the same as or slightly smaller than the internal diameter of the tube of aerosol-forming substrate. In that case, if a thermally insulating material is provided, it may be provided to surround the aerosol-forming substrate.

In both aspects of the invention, the at least one heater may comprise an end heater for heating the end of the aerosol-forming substrate, the end heater comprising one or more electrically conductive tracks on an electrically insulating substrate. In one embodiment, the end heater comprises a spiral electrically conductive track on a circular or substantially circular electrically insulating substrate.

In both aspects of the invention, the electrically conductive tracks preferably comprise an electrically resistive material. More preferably, the electrically conductive tracks are metallic. Most preferably, the electrically conductive tracks comprise one or more of: silver, platinum, copper, nickel and palladium. Other materials are possible, for example electrically "conductive" ceramics (such as, for example, molybdenum disilicide), carbon, graphite, metal alloys and composite materials made of a ceramic material and a metallic material. Such composite materials may comprise doped or undoped ceramics. Examples of suitable doped ceramics include doped silicon carbides. Examples of suitable metals, as well as those listed above, include titanium, zirconium and tantalum. Examples of suitable metal alloys include stainless steel, nickel-, cobalt-, chromium-, aluminium- titanium- zirconium-, hafnium-, niobium-, molybdenum-, tantalum-, tungsten-, tin-, gallium-, manganese- and iron-containing alloys, and super-alloys based on nickel, iron, cobalt, stainless steel, Timetal® and iron-manganese-aluminium based alloys. Timetal® is a registered trade mark of Titanium Metals Corporation, 1999 Broadway Suite 4300, Denver, Colorado. In composite materials, the electrically resistive material may optionally be embedded in, encapsulated or coated with an insulating material or vice-versa, depending on the kinetics of energy transfer and the external physicochemical properties required.

In both aspects of the invention, the electrically conductive tracks may be plated with a protective layer. The electrically conductive tracks may be plated with one or more of: gold, nickel

and glass. Plating the electrically conductive tracks may be advantageous if the electrically conductive tracks comprise a material which will readily oxidize or corrode in some way.

In both aspects of the invention, preferably, the electrically insulating substrate comprises one or more of: paper, glass, ceramic, anodized metal, coated metal, and Polyimide. The ceramic may comprise mica, Alumina (Al_2O_3) or Zircona (ZrO_2). Other suitable materials may be used.

In a first embodiment of either aspect of the invention, the at least one heater is formed by: providing the electrically insulating substrate; depositing an electrically conductive paste onto the electrically insulating substrate using a template to define a pattern for the electrically conductive paste; and drying the electrically conductive paste to form the electrically conductive tracks.

In that first embodiment, the electrically insulating substrate may be any suitable electrically insulating material but is preferably a ceramic or an anodized metal. In that first embodiment, the electrically conductive paste may be any suitable paste but preferably includes metal particles. The metal may be silver. The electrically conductive paste may also include binders and plasticizers.

In a second embodiment of either aspect of the invention, the at least one heater is formed by: providing the electrically insulating substrate; covering substantially the entire surface of the electrically insulating substrate with an electrically conductive material; protecting portions of the electrically conductive material with a mask defining a pattern for the electrically conductive material; and removing the unprotected portions of the electrically conductive material.

In that second embodiment, the electrically insulating substrate may be any suitable electrically insulating material but is preferably polyimide. In that second embodiment, the electrically conductive material may be any suitable material but preferably includes metal alloys. The metal may be copper. The electrically conductive tracks may be plated with one or more protective layers. In one embodiment, the copper electrically conductive tracks are plated with a first layer of nickel and a second layer of gold.

In a third embodiment of either aspect of the invention, the at least one heater is formed by: providing the electrically insulating substrate; coating the electrically insulating substrate with a metal film; coating the metal film with a layer of photoresist material; protecting portions of the photoresist material with a mask defining a pattern for the electrically conductive paste; removing the unprotected portions of the photoresist material using a light source and chemicals (the exposed photoresist material being soluble in specific solution); removing the portions of the metal film unprotected by the photoresist material; and removing the remaining photoresist material to reveal the metal film in the form of the electrically conductive tracks.

In that third embodiment, the electrically insulating substrate may be any suitable electrically insulating material but is preferably ceramic. Most preferably, the substrate is Alumina (Al_2O_3) or

Zirconia (ZrO_2). In that third embodiment, the metal film may be any suitable metal film but is preferably platinum film. The electrically conductive tracks may be plated with one or more protective layers. In one embodiment, the electrically conductive tracks are plated with a layer of glass.

In both aspects of the invention, the aerosol-forming substrate preferably comprises a tobacco-containing material containing volatile tobacco flavour compounds which are released from the aerosol-forming substrate upon heating. Alternatively, the aerosol-forming substrate may comprise a non-tobacco material.

In both aspects of the invention, preferably, the aerosol-forming substrate further comprises an aerosol former. Examples of suitable aerosol formers are glycerine and propylene glycol.

In both aspects of the invention, the aerosol-forming substrate is preferably a solid substrate. In a preferred embodiment, the aerosol-forming substrate comprises a tubular substrate having a cavity for receiving the at least one heater. The solid substrate may comprise, for example, one or more of: powder, granules, pellets, shreds, spaghettis, strips or sheets containing one or more of: herb leaf, tobacco leaf, fragments of tobacco ribs, reconstituted tobacco, homogenised tobacco, extruded tobacco and expanded tobacco. The solid substrate may be in loose form, or may be provided in a suitable container or cartridge. Optionally, the solid aerosol-forming substrate may contain additional tobacco or non-tobacco volatile flavour compounds, to be released upon heating of the substrate.

In both aspects of the invention, optionally, the solid aerosol-forming substrate may be provided on or embedded in a thermally stable carrier. In a preferred embodiment, the carrier is a tubular carrier having a thin layer of the solid substrate deposited on its inner surface, or on its outer surface, or on both its inner and outer surfaces. Such a tubular carrier may be formed of, for example, a paper, or paper like material, a non-woven carbon fibre mat, a low mass open mesh metallic screen, or a perforated metallic foil or any other thermally stable polymer matrix. Alternatively, the carrier may take the form of powder, granules, pellets, shreds, spaghettis, strips or sheets.

In both aspects of the invention, the solid aerosol-forming substrate may be deposited on the surface of the carrier in the form of, for example, a sheet, foam, gel or slurry. The solid aerosol-forming substrate may be deposited on the entire surface of the carrier, or alternatively, may be deposited in a pattern in order to provide a non-uniform flavour delivery during use.

In both aspects of the invention, alternatively, the carrier may be a non-woven fabric or fibre bundle into which tobacco components have been incorporated. The non-woven fabric or fibre bundle may comprise, for example, carbon fibres, natural cellulose fibres, or cellulose derivative

fibres.

In both aspects of the invention, alternatively, the aerosol-forming substrate may be a liquid substrate. If a liquid aerosol-forming substrate is provided, the electrically heated smoking system preferably comprises means for retaining the liquid. For example, the liquid aerosol-forming substrate may be retained in a container. Alternatively or in addition, the liquid aerosol-forming substrate may be absorbed into a porous carrier material. The porous carrier material may be made from any suitable absorbent plug or body, for example, a foamed metal or plastics material, polypropylene, terylene, nylon fibres or ceramic. The liquid aerosol-forming substrate may be retained in the porous carrier material prior to use of the electrically heated smoking system or alternatively, the liquid aerosol forming substrate material may be released into the porous carrier material during, or immediately prior to use. For example, the liquid aerosol-forming substrate may be provided in a capsule. The shell of the capsule preferably melts upon heating and releases the liquid aerosol-forming substrate into the porous carrier material. The capsule may optionally contain a solid in combination with the liquid.

If the aerosol-forming substrate is a liquid aerosol-forming substrate, the electrically heated smoking system may further comprise means for heating a small amount of liquid at a time. The means for heating a small amount of liquid at a time may include, for example, a liquid passageway in communication with the liquid substrate. The liquid aerosol-forming substrate is typically forced into the liquid passageway by capillary force. The at least one heater is preferably arranged such that during use, only the small amount of liquid aerosol-forming substrate within the liquid passageway, and not the liquid within the container, is heated and volatilised.

Alternatively, or in addition, if the aerosol-forming substrate is a liquid aerosol-forming substrate, the electrically heated smoking system may further comprise an atomiser in contact with the liquid aerosol-forming substrate source and including the at least one heater. In addition to the heater, the atomiser may include one or more electromechanical elements such as piezoelectric elements. Additionally or alternatively, the atomiser may also include elements that use electrostatic, electromagnetic or pneumatic effects. The electrically heated smoking system may still further comprise a condensation chamber.

In both aspects of the invention, the aerosol-forming substrate may alternatively be any other sort of aerosol-forming substrate, for example, a gas aerosol-forming substrate, or any combination of the various types of aerosol-forming substrate.

In both aspects of the invention, during operation, the aerosol-forming substrate may be completely contained within the electrically heated smoking system. In that case, a user may puff on a mouthpiece of the electrically heated smoking system. Alternatively, during operation, the

aerosol-forming substrate may be partially contained within the electrically heated smoking system. In that case, the aerosol-forming substrate may form part of a separate article and the user may puff directly on the separate article.

In both aspects of the invention, the electrically heated smoking system may further comprise a sensor to detect air flow indicative of a user taking a puff. In that embodiment, preferably, the sensor is connected to the power supply and the system is arranged to energise the at least one heater when the sensor senses a user taking a puff. Alternatively, the system may further comprise a manually operable switch, for a user to initiate a puff.

In both aspects of the invention preferably, the electrically heated smoking system further comprises a housing for receiving the aerosol-forming substrate and designed to be grasped by a user. The housing preferably houses the at least one heater, the power supply and any other components required for the system, such as electronic circuitry. In one embodiment, the housing comprises a shell and a replaceable mouthpiece.

In both aspects of the invention, in one preferred embodiment, the power supply is a DC voltage source. In one embodiment, the power supply is a Lithium-ion battery. Alternatively, the power supply may be a Nickel-metal hydride battery, a Nickel cadmium battery or a Lithium Phosphate battery.

Features described in relation to one aspect of the invention may also be applicable to another aspect of the invention. In particular, features and advantages of the one or more electrically conductive tracks acting as both a resistive heater and as a temperature sensor described in relation to the first aspect of the invention may also be applicable to the second aspect of the invention. Features and advantages of the thermally insulating material described in relation to the second aspect of the invention may also be applicable to the first aspect of the invention.

The invention will be further described, by way of example only, with reference to the accompanying drawings, in which:

Figures 1a to 1d show a first embodiment of a method for forming a heater for an electrical smoking system;

Figures 2a to 2e show a second embodiment of a method for forming a heater for an electrical smoking system;

Figures 3a to 3f show a third embodiment of a method for forming a heater for an electrical smoking system;

Figure 4 shows a first embodiment of a heater for use in an electrically heated smoking system; and

Figures 5a and 5b show a second embodiment of a heater for use in an electrically heated

smoking system.

As discussed above, the invention provides an electrically heated smoking system including a heater. The heater comprises one or more electrically conductive tracks on an electrically insulating substrate. The heater may be formed by a number of different manufacturing processes. Figures 1a to 1d show a first manufacturing process. Figures 2a to 2d show a second manufacturing process. Figures 3a to 3d show a third manufacturing process.

Figures 1a to 1d show a manufacturing process using a technique similar to that used in screen printing. This manufacturing process may be used with the first or second aspect of the invention. Referring to Figure 1a, firstly an electrically insulating substrate 101 is provided. The electrically insulating substrate may comprise any suitable electrically insulating material, for example, but not limited to, a ceramic such as MICA, glass or paper. Alternatively, the electrically insulating substrate may comprise an electrical conductor that is insulated from the electrically conductive tracks (produced in Figure 1b and discussed below), for example, by oxidizing or anodizing its surface or both. One example is anodized aluminium. Alternatively, the electrically insulating substrate may comprise an electrical conductor to which is added an intermediate coating called a glaze. In that case, the glaze has two functions: to electrically insulate the substrate from the electrically conductive tracks, and to reduce bending of the substrate. Folds existing in the electrically insulating substrate can lead to cracks in the electrically conductive paste (applied in Figure 1b and discussed below) causing defective resistors.

Referring to Figure 1b, the electrically insulating substrate is held securely, such as by a vacuum, while a metal paste 105 is coated onto the electrically insulating substrate using a cut out 107. Any suitable metal paste may be used but, in one example, the metal paste is silver paste. In one particularly advantageous example, the paste comprises 20% to 30% of binders and plasticizers and 70% to 80% of metal particles, typically silver particles. The cut out 107 provides a template for the desired electrically conductive tracks. After the metal paste 105 has been coated onto the electrically insulating substrate 101, the electrically insulating substrate and paste are fired, for example, in a sintering furnace. In a first firing phase at between 200°C and 400°C, the organic binders and solvents are burned out. In a second firing phase at between 350°C and 500°C the metal particles are sintered.

Referring to Figure 1c, the result is an electrically insulating substrate 101 having an electrically conductive track or tracks 103 thereon. The electrically conductive track or tracks comprises heating resistors and the necessary connection pads.

Finally, the electrically insulating substrate 101 and electrically conductive tracks 103 are formed into the appropriate form for use as a heater in an electrically heated smoking system.

Referring to Figure 1d, the electrically insulating substrate 101 may be rolled into tubular form, such that the electrically conductive tracks lie on the inside of the electrically insulating substrate (Figure 1d(i)). In that case, the tube may function as an external heater for a solid plug of aerosol-forming material. The internal diameter of the tube may be the same as or slightly bigger than the diameter of the aerosol-forming plug. Alternatively, the electrically insulating substrate 101 may be rolled into tubular form, such that the electrically conductive tracks lie on the outside of the electrically insulating substrate (Figure 1d(ii)). In that case, the tube may function as an internal heater and can be inserted directly into the aerosol-forming substrate. This may work well when the aerosol-forming substrate takes the form of a tube of tobacco material, for example, such as tobacco mat. In that case, the external diameter of the tube may be the same as or slightly smaller than the internal diameter of the aerosol-forming substrate tube. Alternatively, if the electrically insulating substrate is sufficiently rigid or is reinforced in some way, some or all of the electrically insulating substrate and electrically conductive tracks may be used directly as an internal heater (Figure 1d(iii)) simply by inserting the electrically insulating substrate and electrically conductive tracks directly into the aerosol-forming substrate.

Figures 2a to 2e show a second manufacturing process for a heater for an electrically heated smoking system. This manufacturing process may be used with the first or second aspect of the invention. This manufacturing process is based on PCB manufacturing technology. Referring to Figure 2a, firstly an electrically insulating substrate 201 is provided. Again, the electrically insulating substrate may comprise any suitable electrically insulating material. In this example, the electrically insulating substrate 201 comprises polyimide.

Referring to Figure 2b, secondly a metal foil 205 is applied over substantially the entire electrically insulating substrate 201. This may be achieved by lamination or by a physical vapour deposition (PVD) process, followed by galvanic reinforcement. Any suitable metal may be used but, in one example, the metal foil is copper. Copper has the advantage that it has a high temperature coefficient of resistance. This may mean that it is relatively straightforward to use the electrically conductive tracks as a temperature sensor as well as a heater. This is discussed more fully below. Other metals may be used, however, for example, but not limited to, nickel or platinum.

After the metal foil 205 has been applied to the electrically insulating substrate, unwanted areas of the copper are removed with a subtractive method. Referring to Figure 2c, typically a mask 207 is used combined with chemical etching, which dissolves the copper in all areas unprotected by the mask. This results in the device shown in Figure 2c which comprises electrically insulating substrate 201 with electrically conductive areas 209.

Referring to Figure 2d, the electrically conductive areas 209 may then be plated. Figure 2d

shows a single electrically conductive area 209 for simplicity. Plating is advantageous if using copper, as copper oxidizes quickly. It may be difficult to solder the copper, to form the necessary connections, if an oxide layer has already formed. In this example, the electrically conductive areas 209 are plated with a double layer comprising a first layer 211 of nickel followed by a second layer 213 of gold. The result is an electrically insulating substrate 201 having an electrically conductive track or tracks 203 thereon. The electrically conductive track or tracks comprises heating resistors and the necessary connection pads.

Finally, the electrically insulating substrate 201 and electrically conductive tracks 203 are formed into the appropriate form for use as a heater in an electrically heated smoking system. Referring to Figure 2e, the electrically insulating substrate 201 may be rolled into tubular form, such that the electrically conductive tracks lie on the inside of the electrically insulating substrate (Figure 2e(i)). In that case, the tube may function as an external heater for an aerosol-forming substrate. Alternatively, the electrically insulating substrate 201 may be rolled into tubular form, such that the electrically conductive tracks lie on the outside of the electrically insulating substrate (Figure 2e(ii)). In that case, the tube may function as an internal heater and can be inserted directly into the aerosol-forming substrate. Alternatively, if the electrically insulating substrate is sufficiently rigid or is reinforced in some way, some or all of the electrically insulating substrate and electrically conductive tracks may be used as an internal heater (Figure 2e(iii)) simply by inserting the electrically insulating substrate and electrically conductive tracks directly into the aerosol-forming substrate.

Note that the method described with reference to Figures 2a to 2e may also be used to form an additional thermally insulating, reflective layer. This will be discussed in detail below.

Figures 3a to 3f show a third manufacturing process for a heater for an electrically heated smoking system. This manufacturing process may be used with the first or second aspect of the invention. This manufacturing process is based on a photolithography technique. Referring to Figure 3a, first an electrically insulating substrate 301 is provided. Again, the electrically insulating substrate may comprise any suitable electrically insulating material. In this example, the electrically insulating substrate 301 comprises a thick ceramic, for example, but not limited to, Alumina (Al_2O_3) or Zirconia (ZrO_2).

Referring to Figure 3b, a structured metal film 305 is formed over the electrically insulating substrate 301. Any suitable metal may be used but, in this example, the metal film is platinum.

Referring to Figure 3c, a photoresist layer 307 is then applied over the metal film 305. The photoresist layer may be applied by any suitable technique, for example, but not limited to spin coating.

Referring to Figure 3d, unwanted areas of the photoresist are removed. This is achieved by using a mask 309 and exposing the photoresist to intense light from a light source 311. A chemical change occurs in the exposed areas of the photoresist, which allows those areas to be subsequently removed by a chemical agent called a developer.

Once the photoresist has been removed in the non protected areas, the metal film 305 is etched by wet or dry etching. This dissolves the metal film in all areas unprotected by the photoresist. Once the metal has been etched, the remaining photoresist is removed by a solvent. This results in the device shown in Figure 3e which comprises electrically insulating substrate 301 with electrically conductive areas 313.

Referring to Figure 3f, finally the electrically insulating substrate 301 and electrically conductive areas 313 may optionally be coated with a passivation layer 315 to prevent corrosion or oxidation of the electrically conductive areas. In this example, the passivation layer is a glass layer. The result is an electrically insulating substrate 301 having an electrically conductive track or tracks 303 thereon. The electrically conductive track or tracks comprises heating resistors and the necessary connection pads.

This heater can be mounted in the electrically heated smoking system using a special frame, for example a metallic clamp, or the heater may be an integral part of a monolithic ceramic base sitting within the electrically heated smoking system.

Figures 4 and 5a and 5b show two alternative embodiments of the heater of the invention.

Figure 4 shows a first embodiment of the heater in use with an aerosol-forming substrate. In Figure 4, the heater 400 comprises a flat, rigid electrically insulating substrate 401 having thereon electrically conductive tracks 403. (The heater may be of the form shown in Figure 1d(iii) or Figure 2e(iii).) The electrically conductive tracks are connectable to a power supply (not shown) via connections 405. The heater 400 may be inserted directly into a plug of aerosol-forming substrate, shown schematically at 407. The heater shown in Figure 4 may be used in either the first or second aspect of the invention. If the electrically conductive tracks have suitable temperature coefficient of resistance characteristics, they may act as resistive heaters as well as a temperature sensor. The heater may be combined with a thermally insulating material for thermally insulating the at least one heater from the outside of the electrically heated smoking system with which it is used.

Figures 5a and 5b show a second embodiment of the heater. In Figures 5a and 5b, the heater comprises an electrically insulating substrate 501. On a first portion 509 of the electrically insulating substrate, there are electrically conductive tracks 503. The electrically conductive tracks 503 are connectable to a power supply (not shown) via connections 505. On a second portion 511 of the electrically insulating substrate 501, a thermally insulating reflective honeycomb structure

507 is formed on the electrically insulating substrate. The heater of Figure 5a is designed to be rolled into a tube from left to right, such that the portion 509 of the electrically insulating substrate having the electrically conductive tracks is on the inside and the portion 511 of the electrically insulating substrate having the thermally insulating honeycomb structure 507 is on the outside. Preferably the thermally insulating material is also highly reflective. The resulting heater is shown schematically in Figure 5b. The honeycomb structure may then be used to thermally insulate the heater and is preferably metal. The heater shown in Figure 5b may be used as an external heater, with the thermally insulating reflective honeycomb structure 507 on the outside so as to insulate the heater from the outside of the electrically heated smoking system with which it is used. This reduces heat loss and also protects a user's hand from burning.

In Figures 5a and 5b, the thermally insulating reflective honeycomb structure is shown as an integral part of the heater. Alternatively, however, the honeycomb structure may be formed separately and used in the electrically heated smoking system as an independent element. For an external heater, the honeycomb structure may be wrapped around the electrically insulating substrate and electrically conductive tracks. For an internal heater, the honeycomb structure may be provided around the aerosol-forming substrate. In addition, alternative structural arrangements for the thermally insulating material are possible.

The heater shown in Figures 5a and 5b may also be used in the first aspect of the invention: if the electrically conductive tracks have suitable temperature coefficient of resistance characteristics, they may act as resistive heaters as well as a temperature sensor.

As already mentioned, the manufacturing process illustrated in Figures 2a to 2e may also be used to create the honeycomb structure 507. In a similar way to Figure 2d, individual areas on the electrically insulating substrate may be plated. If the underlying area is then dissolved or removed in another way, the plating will form air cavities providing thermal insulation. In a preferred arrangement, the air cavities are provided in a honeycomb structure, but other arrangements are also envisaged. In addition, the greatest thermal insulation is provided when several layers of the thermally insulating structure are used, for example, by rolling around or stacking up several layers. Advantageously, the plating may comprise only a single layer of gold. Gold is particularly useful as it will also reflect heat towards the inside of the electrically heated smoking system, further reducing heat loss. Alternatively, the plating may comprise a single layer of another metal, such as silver. Alternatively, the plating may comprise two layers, similar to that shown in Figure 2d.

A number of advantages are provided by using a heater comprising electrically conductive tracks formed on an electrically insulating substrate. The size of components required in the electrically heated smoking system can be reduced. This allows the size of the electrically heated

smoking system to be reduced. In addition, the electrically insulating substrate can be very thin allowing further size reduction. In addition, some or all of the necessary electronics, wiring and connections may be incorporated on the same electrically insulating substrate as the heater.

In addition, the heater may be manufactured more straightforwardly and cost effectively than some prior art heaters which require each heating element to be individually formed. The heater allows a great deal of flexibility in the design: the electrically conductive tracks can be straightforwardly arranged on the electrically insulating substrate as desired and in order to give the desired heat distribution.

In addition, assuming the material used for the electrically conductive tracks has appropriate temperature coefficient of resistance characteristics, the electrically conductive tracks can act both as resistive heaters and as a temperature sensor. This can further reduce the size of the electrically heated smoking system, since no separate temperature sensor will be required. This will now be described in more detail.

The temperature coefficient of resistance is a measure of the change in resistance with a given change in temperature. The general formula is given by:

$$R = R_0(1 + \alpha T)$$

where R is resistance, R_0 is the resistance at a given temperature (usually 0 °C), T is the temperature, and α is the temperature coefficient of resistance. The temperature dependence of conductors is substantially linear.

In one method, the voltage across and the current through the electrically conductive track may be measured and the resistance determined. Then, assuming knowledge of R_0 and α (both of which will be known for a given material), the temperature may be determined. That is to say, the electrically conductive track can act as temperature sensor as well as a resistive heater.

The material must have a reasonably reliable temperature coefficient of resistance, α . That is to say, one that does not change considerably over time or under certain conditions. In addition, there may be advantages in using a material having a large value of the temperature coefficient of resistance, α , since this will mean that a relatively small change in temperature results in a large change in resistance. Materials having a large value of α include platinum, nickel and copper.

WE CLAIM:

1. An electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising:

 at least one heater for heating the aerosol-forming substrate to form an aerosol, a power supply for supplying power to the heater, the heater comprising one or more electrically conductive tracks on an electrically insulating substrate, the one or more electrically conductive tracks comprising a plurality of portions, each portion being separately connectable to the power supply,

 electronic circuitry arranged to control supply of power from the power supply to the at least one heater so that different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.
2. An electrically heated smoking system according to claim 1, wherein the electrically insulating substrate is tubular.
3. An electrically heated smoking system according to claim 1 or 2, wherein the one or more electrically conductive tracks are on the inside of the tubular electrically insulating substrate.
4. An electrically heated smoking system according to claim 1 or 2, wherein the one or more electrically conductive tracks are on the outside of the tubular electrically insulating substrate.
5. An electrically heated smoking system according to any one of claims 1 to 4, further comprising a thermally insulating element for insulating the at least one heater, wherein the thermally insulating element comprises a metal.
6. An electrically heated smoking system according to any one of claims 1 to 5, wherein the electrically insulating substrate is formed from polyimide.
7. An electrically heated smoking system according to any one of claims 1 to 6, wherein the electrically conductive tracks comprise stainless steel.

8. An electrically heated smoking system according to any one of claims 1 to 7, wherein the system comprises an aerosol-forming substrate comprising a tobacco-containing material containing volatile tobacco flavour compounds which are released from the aerosol-forming substrate upon heating.
9. An electrically heated smoking system according to claim 8, wherein during operation, the aerosol-forming substrate is partially contained within the electrically heated smoking system.
10. An electrically heated smoking system according to claim 9, wherein the aerosol-forming substrate forms part of a separate article and during operation the user puffs directly on the separate article.
11. Use of a heater in an electrically heated smoking system, the electrically heated smoking system comprising a power supply for supplying power to the heater, the heater comprising one or more electrically conductive tracks on an electrically insulating substrate, the one or more electrically conductive tracks comprising a plurality of portions, each portion being separately connectable to the power supply,

wherein different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.
12. An electrically heated smoking system according to claim 11, wherein the at least one heater surrounds or partially surrounds the aerosol-forming substrate.
13. An electrically heated smoking system according to claim 12, wherein the thermally insulating element comprises a cavity.
14. An electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising:

a housing for receiving the aerosol-forming substrate; at least one heater for heating the aerosol-forming substrate to form an aerosol, a power supply for supplying power to the at

least one heater, electronic circuitry arranged to control a supply of power from the power supply to the at least one heater, and a thermally insulating element for insulating the at least one heater,

wherein the thermally insulating element comprises a metal, wherein the at least one heater comprises one or more electrically conductive, stainless steel tracks on an electrically insulating substrate, wherein the one or more electrically conductive tracks comprise a plurality of portions, each portion being separately connectable to the power supply, wherein the electrically insulating substrate is formed from polyimide and is rolled into a tube, and wherein the housing is designed to be grasped by a user and houses the at least one heater, the thermally insulating element, the power supply and the electronic circuitry.

15. An electrically heated smoking system according to claim 14, further comprising electronic circuitry arranged to control supply of power from the power supply to the at least one heater so that different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.
16. An electrically heated smoking system according to claim 14 or 15, wherein the one or more electrically conductive tracks are on the inside of the tube of electrically insulating substrate.
17. An electrically heated smoking system according to claim 14 or 15, wherein the one or more electrically conductive tracks are on the outside of the tube of electrically insulating substrate.
18. An electrically heated smoking system according to any one of claims 14 to 17, wherein the system comprises an aerosol-forming substrate comprising a tobacco-containing material containing volatile tobacco flavour compounds which are released from the aerosol-forming substrate upon heating.
19. An electrically heated smoking system according to claim 18, wherein during operation, the aerosol-forming substrate is partially contained within the electrically heated smoking system.

20. An electrically heated smoking system according to claim 19, wherein the aerosol-forming substrate forms part of a separate article and during operation the user puffs directly on the separate article.
21. An electrically heated smoking system according to claim 14, wherein the at least one heater surrounds or partially surrounds the aerosol-forming substrate.
22. An electrically heated smoking system according to claim 14, wherein the thermally insulating element comprises a cavity.
23. An electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising:

at least one heater for heating the aerosol-forming substrate to form an aerosol, and a power supply for supplying power to the at least one heater, wherein the at least one heater comprises one or more electrically conductive tracks on an electrically insulating substrate, wherein the electrically insulating substrate is formed from polyimide and is tubular,

wherein each portion of the aerosol-forming substrate is heated only once and not reheated.
24. An electrically heated smoking system according to claim 23, further comprising a thermally insulating element for insulating the at least one heater, wherein the thermally insulating element comprises a metal.
25. An electrically heated smoking system according to claim 23 or 24, wherein the one or more electrically conductive tracks comprise a plurality of portions, each portion being separately connectable to the power supply.
26. An electrically heated smoking system according to claim 25, further comprising electronic circuitry arranged to control supply of power from the power supply to the at least one heater so that different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.

27. An electrically heated smoking system according to any one of claims 23 to 26, wherein the one or more electrically conductive tracks are on the inside of the tube of electrically insulating substrate.
28. An electrically heated smoking system according to any one of claims 23 to 26, wherein the one or more electrically conductive tracks are on the outside of the tube of electrically insulating substrate.
29. An electrically heated smoking system according to any one of claims 23 to 28, wherein the electrically insulating substrate is rolled into tube.
30. An electrically heated smoking system according to any one of claims 23 to 29, wherein the system comprises an aerosol-forming substrate comprising a tobacco-containing material containing volatile tobacco flavour compounds which are released from the aerosol-forming substrate upon heating.
31. An electrically heated smoking system according to claim 30, wherein during operation, the aerosol-forming substrate is partially contained within the electrically heated smoking system.
32. An electrically heated smoking system according to claim 31, wherein the aerosol-forming substrate forms part of a separate article and during operation the user puffs directly on the separate article.
33. An electrically heated smoking system according to claim 23, wherein the at least one heater surrounds or partially surrounds the aerosol-forming substrate.
34. An electrically heated smoking system according to claim 24, wherein the thermally insulating element comprises a cavity.
35. Use of a heater in an electrically heated smoking system, the electrically heated smoking system comprising a power supply for supplying power to the heater, the heater comprising one or more electrically conductive tracks on an electrically insulating substrate, the one

or more electrically conductive tracks comprising a plurality of portions, each portion being separately connectable to the power supply,

wherein different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.

36. An electrically heated smoking system for receiving an aerosol-forming substrate, the system comprising:

a power supply for supplying power to the at least one heater; and

at least one heater for heating the substrate to form the aerosol, the at least one heater comprising a single track of electrically conductive material on an electrically insulating substrate, wherein the electrically insulating substrate is tubular, a first end of the single track being connectable to the power supply and a second end of the single track being connectable to the power supply,

wherein the power supply is also connectable to one or more central sections of the single track to provide a plurality of portions, each portion being separately connectable to the power supply.

37. An electrically heated smoking system according to claim 36, further comprising electronic circuitry arranged to control supply of power from the power supply to the at least one heater so that different portions of the one or more electrically conductive tracks are heated for different durations, or to different temperatures, or both for different durations and different temperatures.
38. An electrically heated smoking system according to claim 36 or 37, wherein the one or more electrically conductive tracks are on the inside of the tubular electrically insulating substrate.
39. An electrically heated smoking system according to claim 36 or 37, wherein the one or more electrically conductive tracks are on the outside of the tubular electrically insulating substrate.

40. An electrically heated smoking system according to any one of claims 36 to 39, further comprising a thermally insulating element for insulating the at least one heater, wherein the thermally insulating element comprises a metal.
41. An electrically heated smoking system according to any one of claims 36 to 40, wherein the electrically insulating substrate is formed from polyimide.
42. An electrically heated smoking system according to any one of claims 36 to 41, wherein the electrically conductive tracks comprise stainless steel.
43. An electrically heated smoking system according to any one of claims 36 to 42, wherein the system comprises an aerosol-forming substrate comprising a tobacco-containing material containing volatile tobacco flavour compounds which are released from the aerosol-forming substrate upon heating.
44. An electrically heated smoking system according to claim 43, wherein during operation, the aerosol-forming substrate is partially contained within the electrically heated smoking system.
45. An electrically heated smoking system according to claim 44, wherein the aerosol-forming substrate forms part of a separate article and during operation the user puffs directly on the separate article.
46. An electrically heated smoking system according to claim 36, wherein the at least one heater surrounds or partially surrounds the aerosol-forming substrate.
47. An electrically heated smoking system according to claim 40, wherein the thermally insulating element comprises a cavity.
