(57) **ABSTRACT**

Systems, devices and methods are provided to improve performance of integrated circuits by providing a low-k insulator. One aspect is an integrated circuit insulator structure. One embodiment includes a solid structure of an insulator material, and a precisely determined arrangement of at least one void formed within the solid structure which lowers an effective dielectric constant of the insulator structure. One aspect is a method of forming a low-k insulator structure. In one embodiment, an insulator material is deposited, and a predetermined arrangement of at least one hole is formed in a surface of the insulator material. The insulator material is annealed such that the low-k dielectric material undergoes a surface transformation to transform the arrangement of at least one hole into predetermined arrangement of at least one empty space below the surface of the insulator material. Other aspects are provided herein.

TECHNICAL FIELD OF THE INVENTION

[0003] This invention relates generally to integrated circuits and, more particularly, to integrated circuit dielectrics useful for reducing the signal delay time attributable to interconnects.

BACKGROUND OF THE INVENTION

[0004] The semiconductor industry continuously strives to reduce the size and cost of integrated circuits. One method for measuring the performance of an integrated circuit uses the maximum clock speed at which the circuit operates reliably, which depends on how fast transistors can be switched and how fast signals can propagate.

[0005] One particular problem confronting the semiconductor industry is that, as integrated circuit scaling continues, the performance improvement is limited by the signal delay time attributable to interconnects in the integrated circuit. According to one definition, integrated circuit interconnects are three-dimensional metal lines with submicrometer cross sections surrounded by insulating material. One definition of an interconnect delay is the product of the interconnect resistance (R) and the parasitic capacitance (C) for the interconnect metal to the adjacent layers. Because of the progressive scaling, the parasitic capacitance (C) has significantly increased due to closer routing of wires, and the interconnect resistance (R) has significantly increased due to a continuous reduction of the wire section.

[0006] The following approximations for various generations of integrated circuit technology illustrates this problem. For example, the delay in 0.7 μm technology is about 500 ps, in which about 200 ps seconds are attributable to gate delays and about 300 ps are attributable to interconnect delays. The delay in 0.18 μm technology is about 230 ps, in which about 30 ps are attributable to gate delays and about 200 ps are attributable to interconnect delays. As integrated circuit scaling continues, it is desirable to lower the interconnect RC time

constant by using metals with a high conductivity. One high conductivity metal used to lower the RC constant is copper. The use of copper in 0.18 μm technology improves the interconnect delays to about 170 ps. However, even though the delay attributable to the gates continues to decrease as scaling continues beyond the 0.18 μm technology, the overall delay increases significantly because the interconnect delay is significantly increased. It has been estimated that as much as 90 percent of the signal delay time in future integrated circuit designs may be attributable to the interconnects and only 10 percent of the signal delay may be attributable to transistor device delays. As such, it is desirable to lower the interconnect RC time constant by using materials with a low dielectric constant (k).

[0007] Low-k dense materials are available having a k in a range between 2.5 and 4.1. The fluorination of dielectric candidates, such as Teflon®, achieve a k of about 1.9.

[0008] Air has a k of about 1. One direction for developing low-k dielectrics incorporates air into dense materials to make them porous. The dielectric constant of the resulting porous material is a combination of the dielectric constant of air (k≈1) and the dielectric constant of the dense material. As such, it is possible to lower the dielectric constant of a low-k dense material by making the dense material porous.

[0009] FIG. 1 illustrates a known Xerogel process for forming porous, silica-based material with a lower dielectric constant (k). Xerogels and Aerogels based on silica incorporate a large amount of air in voids, such that dielectric constants of 1.95 and lower have been achieved with voids that are as small as 5-10 nm. However, it is difficult to control the preparation of Xerogel and Aerogel low-k films. Furthermore, large amounts of liquid solvents and non-solvents have to be removed to form the voids, which tend to produce variability in the void size, shape and density, and tend to produce shrinkage that can cause high internal stress and cracking.

[0010] Therefore, there is a need in the art to provide a system and method that improves integrated circuit performance by reducing the interconnect RC time constant. There is a need in the art to provide a low-k dielectric insulator for the interconnects that is easily prepared, that is consistently formed and that does not suffer from high internal stress and cracking.

SUMMARY OF THE INVENTION

[0011] The above mentioned problems are addressed by the present subject matter and will be understood by reading and studying the following specification. The present subject matter provides a low-k dielectric insulator for integrated circuit interconnects that is easily prepared, that is consistently formed and that does not suffer from high internal stress and cracking. The low-k dielectric insulator of the present invention includes empty spaces formed using surface transformation. As such, the present invention provides a system and method that improves integrated circuit performance by reducing the interconnect RC time constant.

[0012] One aspect of the present subject matter is an integrated circuit insulator structure. One embodiment of the structure includes a solid structure of an insulator material, and a precisely determined arrangement of at least one void formed within the solid structure. The precisely-determined arrangement of at least one void within the solid structure lowers an effective dielectric constant of the insulator structure. According to one embodiment of the structure, the precisely determined arrangement of at least one void is formed

within the solid structure by surface transformation. According to various embodiments, the at least one void includes spherical, pipe-shaped and plate-shaped voids.

[0013] One aspect of the present subject matter is a method of forming a low-k insulator structure. In one embodiment, an insulator material is deposited, and a predetermined arrangement of at least one hole is formed in a surface of the insulator material. In one embodiment, the at least one hole includes a cylindrical hole. The insulator material is annealed such that the low-k dielectric material undergoes a surface transformation to transform the arrangement of at least one hole into predetermined arrangement of at least one empty space below the surface of the insulator material. According to various embodiments, the predetermined arrangement of at least one hole is formed as one or more spheres, one or more plate-shaped voids, and/or one or more pipe-shaped voids.

[0014] One aspect of the present subject matter is a method of forming an integrated circuit. In one embodiment, an inter-layer insulator is formed and a metal level is formed on the inter-layer insulator. The interlayer insulator is formed by depositing a low-k, relatively low melting dielectric material. A predetermined arrangement of holes is formed in a surface of the low-k dielectric material. The low-k dielectric material is annealed such that the low-k dielectric material undergoes a surface transformation to transform the arrangement of at least one hole into a predetermined arrangement of at least one empty space below the surface of the low-k dielectric material. According to various embodiments, the holes are formed and the material is annealed either before or after the metal level is formed on the inter-layer insulator.

[0015] These and other aspects, embodiments, advantages, and features will become apparent from the following description of the invention and the referenced drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0016] FIG. 1 illustrates a known Xerogel process for forming porous, silica-based material with a lower dielectric constant (k).

[0017] FIGS. 2A-2F illustrate a portion of a silicon substrate undertaking a sequence of steps for single sphere-shaped empty space formation.

[0018] FIGS. 3A-3C illustrate a portion of a silicon substrate undertaking a sequence of steps for single pipe-shaped empty space formation.

[0019] FIGS. 4A-4B illustrate a portion of a silicon substrate undertaking a sequence of steps for plate-shaped empty space formation.

[0020] FIG. 5 illustrates a parallel capacitor model for two distinct dielectrics in parallel with each other, the first dielectric having a permittivity of ϵ_1 , or a permittivity of free space (ϵ_0), and the second dielectric having a permittivity of ϵ_2 .

[0021] FIG. 6 illustrates a series capacitor model for two distinct dielectrics in series with each other, the first dielectric having a permittivity of ϵ_1 , or a permittivity of free space (ϵ_0), and the second dielectric having a permittivity of ϵ_2 .

[0022] FIG. 7 illustrates plots of $k_{eff(P)}$ and $k_{eff(S)}$ which are plotted as a function of the filling factor "F", which is shown in FIGS. 5 and 6, and for k_2 equal to 4.0.

[0023] FIG. 8 illustrates a transformation formed stack of empty plates with a filling factor "F" approximately equal to 0.78 and an effective dielectric constant k_{eff} approximately equal to 1.2.

[0024] FIG. 9 illustrates metal levels for an integrated circuit.

[0025] FIG. 10 illustrates a dielectric volume, such as that bounded by the metal levels shown in FIG. 9, with a single empty sphere formed therein.

[0026] FIG. 11 illustrates a dielectric volume, such as that bounded by the metal levels shown in FIG. 9, with a close-pack structure of spheres formed therein.

[0027] FIG. 12 illustrates a dielectric volume, such as that bounded by the metal levels shown in FIG. 9, with a stack of empty plates formed therein.

[0028] FIG. 13 illustrates the binary system $\{K_2O-Al_2O_3-4SiO_2\}$ leucite-SiO₂.

[0029] FIG. 14 illustrates a phase equilibrium diagram of the ternary system Na₂-CaO-SiO₂ showing boundary curves and tie-lines.

[0030] FIG. 15 illustrates a phase equilibrium diagram of ternary system Na₂-CaO-SiO₂ showing isotherms.

[0031] FIG. 16 illustrates one embodiment for forming a integrated circuit.

[0032] FIG. 17 illustrates one embodiment for forming a low-k insulator for device isolation regions and/or inter-layer dielectrics.

[0033] FIG. 18 is a simplified block diagram of a high-level organization of an electronic system according to the teachings of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0034] The following detailed description of the invention refers to the accompanying drawings which show, by way of illustration, specific aspects and embodiments in which the invention may be practiced. In the drawings, like numerals describe substantially similar components throughout the several views. These embodiments are described in sufficient detail to enable those skilled in the art to practice the invention. Other embodiments may be utilized and structural, logical, and electrical changes may be made without departing from the scope of the present invention. The following detailed description is, therefore, not to be taken in a limiting sense, and the scope of the present invention is defined only by the appended claims, along with the full scope of equivalents to which such claims are entitled.

[0035] The present subject matter improves integrated circuit performance by reducing the RC time delays attributable to interconnects. The present subject matter provides a low-k dielectric insulator of greater uniformity and dimensional stability for advanced integrated circuits. The low-k dielectric insulator of the present invention includes empty spaces, which reduces the effective dielectric constant (k_{eff}) of the insulator, that are controllably formed using surface transformation.

[0036] As analyzed by Nichols et al. (F. A. Nichols et al., Trans. AIME 233, (10), p 1840, 1965) when a solid is heated to a higher temperature, a solid with a cylindrical hole that is beyond a critical length (λ_c) becomes unstable. The cylindrical hole is transformed into one or more empty spheres formed along the cylinder axis. The number (N) of spheres formed depends on the length (L) and radius (R_c) of the cylinder. Two models of diffusion are surface diffusion and pure volume diffusion. With respect to surface diffusion, for example, the relation between the cylinder length (L), cylinder radius (R_c), and number of spheres (N) is expressed by the following equation:

$$8.89 \times R_c \times N \leq L \leq 8.89 \times R_c \times (N+1). \quad (1)$$

Equation (1) predicts that no empty spheres will form if $L < 8.89 \times R_C$. Each empty sphere that forms has a radius (R_S) expressed by the following equation:

$$R_S = 1.88 \times R_C \quad (2)$$

If the cylinder has sufficient length L to form two spheres, the center-to-center spacing between the spheres corresponds to the critical length (λ_C) and is provided by the equation:

$$\lambda_C = 8.89 \times R_C \quad (3)$$

Pure volume diffusion provides similar results, with slightly different constants. For example, depending on the exact magnitude of the diffusion parameters, λ_C can vary from $9.02 \times R_C$ to $12.96 \times R_C$. One of ordinary skill in the art will understand that the diffusion model is capable of being determined by experiment. The remainder of this disclosure assumes surface diffusion. One of ordinary skill in the art will understand, upon reading and comprehending this disclosure, how to apply the teachings of the present invention to another diffusion model.

[0037] As analyzed by Sato et al. (T. Sato et al., VLSI Dig., p 206, 1998), a deep trench in silicon, which has a melting temperature of 1400°C ., is transformed into empty spheres along the axis of the original trench at a reducing ambient of 10 Torr of hydrogen and an annealing temperature of 1100°C . The empty spheres are uniformly sized and spaced.

[0038] As analyzed by Sato et al. (T. Sato et al., 1999 IEDM Digest, paper 20.6.1), various shaped empty spaces such as spheres, pipes, and plates are capable of being formed under the surface of a silicon substrate. The shape of the empty spaces formed during the annealing conditions depends on the size, number and spacing of the cylindrical holes that are initially formed at a lower temperature.

[0039] FIGS. 2A-2F illustrate a portion of a silicon substrate undertaking a sequence of steps for single sphere-shaped empty space formation. A cylindrical hole **210** is formed in the surface **212** of a volume of a solid material **214**. As used here, the term hole refers to a void defined by the solid material. The material **214** is heated (annealed) and undergoes the transformation illustrated in FIGS. 2B through 2F. The result of the surface transformation process is an empty sphere formed below the surface **212** of the volume of material **214**.

[0040] In order to form a single sphere, which holds true for forming a single pipe or plate, the length (L) and radius (R_C) of the cylindrical holes are chosen such that equation (1) with $N=1$ is satisfied. It is pointed out that a vertical stacking of N empty spaces results if the length of the cylindrical holes is such that equation (1) is satisfied.

[0041] In order for single surface-transformed spheres to combine with other surface-transformed spheres, the center-to-center spacing (D_{NT}) between the initial cylindrical holes will satisfy the following equation:

$$2 \times R_C < D_{NT} < 3.76 \times R_C \quad (4)$$

Satisfying this equation prevents the adjacent initial cylindrical holes from touching, yet allows the adjacent surface-transformed spheres to combine and form pipe and plate empty spaces, as shown in FIGS. 3A-3C and FIGS. 4A-4B and described below.

[0042] FIGS. 3A-3C illustrate a portion of a silicon substrate undertaking a sequence of steps for single pipe-shaped empty space formation. A linear array of cylindrical holes **310** is formed in a surface **312** of a solid material **314**. The cylindrical holes **310** have a center-to-center spacing (D_{NT}) as

calculated using equation (4). The material **314** is heated (annealed) and undergoes the transformation illustrated in FIGS. 3B through 3C. The result of the surface transformation process is an empty pipe-shaped void **318** formed below the surface **312** of the volume of material **314**. The radius (R_P) of the pipe **318** is provided by the following equation:

$$R_P = \sqrt{\frac{8.86 \times R_C^3}{D_{NT}}} \quad (5)$$

[0043] FIGS. 4A-4B illustrate a portion of a silicon substrate undertaking a sequence of steps for plate-shaped empty space formation. A two-dimensional array of cylindrical holes **410** is formed in a surface **412** of a solid material **414**. The cylindrical holes **410** have a center-to-center spacing (D_{NT}) as calculated using equation (4). The material **414** is heated (annealed) and undergoes the transformation illustrated in FIG. 4B. The result of the surface transformation process is an empty plate-shaped void **420** formed below the surface **412** of the volume of material **414**. The thickness (T_P) of a plate **420** is given by the following equation:

$$T_P = \frac{27.83 \times R_C^3}{D_{NT}^2} \quad (6)$$

[0044] The present subject matter forms low-k materials using surface transformation. That is, the present subject matter incorporates surface transformation formed empty spaces to lower the effective dielectric (k_{eff}) of an insulator. The size, shape and spacing of empty spaces is controlled by the diameter, depth and spacing of cylindrical holes initially formed in a solid dielectric material that has a defined melting temperature. Empty spaces or voids are formed after annealing below the defined melting temperature. The empty spaces or voids are capable of being formed with a spherical, pipe, or plate shape, or combinations of these shapes.

[0045] The surface transformed empty spaces do not provide additional stress or produce a tendency to crack because the volume of air incorporated in the surface transformed empty spaces is equal to the volume of air within the initial starting pattern of cylindrical holes. It is noted that if the cylinder length (L) is equal to an integer of a critical length (λ_C) such as $1 \times \lambda_C$ to form one sphere, $2 \times \lambda_C$ to form two spheres, $3 \times \lambda_C$ to form three spheres, etc., then the surface will be smooth after the surface transformed empty spaces are formed. However, if the cylinder length (L) is not equal to an integer of a critical length (λ_C), then the surface will have dimples caused by air in the cylinder attributable to the length beyond an integer of a critical length (λ_C). That is, for a given length L and λ_C , the number of spheres formed is the integer of L/λ_C , and the remainder of L/λ_C contributes to the dimples on the surface.

[0046] FIG. 5 illustrates a parallel capacitor model for two distinct dielectrics in parallel with each other, the first dielectric having a permittivity of ϵ_1 , or a permittivity of free space (ϵ_0), and the second dielectric having a permittivity of ϵ_2 . The capacitor **522** has a first electrode **524** and a second electrode **526**. The first electrode **524** and the second electrode **526** both have a length (A) and are separated by a distance (d). A first dielectric **528** is formed between the first

and second electrodes, and a second dielectric **530** is formed between the first and second electrodes and parallel to the first dielectric. The first dielectric extends a distance A_1 , which is a fraction of the length A , from one end of the electrodes as provided by the following equation:

$$A_1 = f \times A. \quad (7)$$

[0047] The variable f represents the fraction (or filling factor) of the first dielectric **528**, which is air ($k \approx 1$) in one embodiment. The second dielectric **530** extends a distance A_2 , which is a fraction of the length A , from the opposing end of the electrodes as provided by the following equation:

$$A_2 = A - A_1 = (1 - f) \times A. \quad (8)$$

The effective dielectric constant ($k_{eff(P)}$) for the parallel capacitor model is represented by the following equation:

$$k_{eff(P)} = f + k_2 \times (1 - f). \quad (9)$$

[0048] FIG. 6 illustrates a series capacitor model for two distinct dielectrics in series with each other, the first dielectric having a permittivity of ϵ_1 , or a permittivity of free space (ϵ_0), and the second dielectric having a permittivity of ϵ_2 . The capacitor **622** has a first electrode **624** and a second electrode **626** both have a length (A) and are separated by a distance (d). A first dielectric **628** is formed in series with a second dielectric **630** between the first and second electrodes. The first dielectric **628** has a width d_1 , which is a fraction of the distance d as represented by the following equation:

$$d_1 = f \times d. \quad (10)$$

The variable f represents the fraction (or filling factor) of the first dielectric **628**, which is air ($k \approx 1$) in one embodiment. The second dielectric has a width d_2 , which is fraction of the distance d as represented by the following equation:

$$d_2 = d - d_1 = (1 - f) \times d. \quad (11)$$

The effective dielectric constant ($k_{eff(S)}$) for the series capacitor model is represented by the following equation:

$$k_{eff(S)} = \frac{1}{f + (1 - f) \times \frac{1}{k_2}}. \quad (12)$$

[0049] FIG. 7 illustrates plots of $k_{eff(P)}$ and $k_{eff(S)}$ which are each plotted as a function of the filling factor variable “ f ” and for k_2 equal to 4.0. One of ordinary skill in the art will recognize that similar plots can be made for other dielectric constant values. The effective dielectric constant (k_{eff}) of a material of dielectric constant k_2 with embedded empty spaces depends on the detailed size, shape orientation and spacing of the empty spaces relative to a set of parallel electrodes. However, the k_{eff} for the material with a dielectric constant k_2 with embedded empty spaces is bounded between the effective capacitance for the parallel capacitor model ($k_{eff(P)}$) and the effective capacitance of the series capacitor model ($k_{eff(S)}$).

[0050] FIG. 8 illustrates a transformation formed stack of empty plates with a filling factor “ f ” approximately equal to 0.78 and an effective dielectric constant k_{eff} approximately equal to 1.2. This figure illustrates one example of the effective dielectric constant (k_{eff}) for a dielectric film of SiO_2 , which has a dielectric constant (k) of 4.34 and a melting temperature of 1610°C ., that incorporates surface transfor-

mation formed empty spaces. In the illustrated example, the surface transformation produces a vertical stack of empty plates in the dielectric film between the electrodes **624** and **626**. The number of empty plates formed depends on the length of the cylindrical holes.

[0051] From equation (6), it is determined that the thickness T_p of the empty plate has a maximum value of $6.95 \times R_C$ when D_{NT} is near the minimum allowed value of $2 \times R_C$ as inferred from equation (4). From equation (3), the center-to-center spacing (λ) of empty plates is $8.89 \times R_C$. It can be calculated that $f \approx 0.78$. The expression of $k_{eff}(s)$ applies and results in $k_{eff} = 1.2$ for $k_2 = 4.34$ and $f = 0.78$.

[0052] FIG. 9 illustrates metal levels for an integrated circuit. The figure illustrates a first metal level **940**, a second metal level **942**, and a third metal level **944**. The metal levels lie in approximately parallel planes. Individual lines within the metal levels typically run either parallel to or orthogonally to individual lines in other metal levels. The metal levels are separated by inter-layer dielectrics (not shown). The metal levels form boundaries for dielectric regions, or volumes, between the individual lines and the metal levels. For simplicity, the dielectric volumes are illustrated as a rectilinear volume in FIGS. 10 through 12. A goal is to maximize the amount of air that is incorporated into these dielectric volumes using surface transformation formed empty spaces.

[0053] FIG. 10 illustrates a dielectric volume **1014**, such as that bounded by the metal levels shown in FIG. 9, with a single empty sphere **1010** formed therein. The dielectric volume often will have various shapes and sizes. As such, smaller spheres are used to obtain a larger filling factor when the empty spheres are packed or arranged with other spheres.

[0054] FIG. 11 illustrates a dielectric volume **1114**, such as that bounded by the metal levels shown in FIG. 9, with a close-pack structure of spheres **1110** formed therein. The spheres **1110** illustrated in FIG. 11 are smaller than the spheres **1010** illustrated in FIG. 10, and as such are capable of being packed into a variety of dielectric volumes.

[0055] FIG. 12 illustrates a dielectric volume, such as that bounded by the metal levels shown in FIG. 9, with a stack of empty plates formed therein. This figure illustrates that other shapes of surface transformation formed empty spaces are capable of being used to lower the effective dielectric constant (k_{eff}) of the dielectric volume. One of ordinary skill in the art will appreciate that various shapes and sizes of voids are capable of being used to pack various shapes and sizes of dielectric volumes.

[0056] In the example above, SiO_2 (quartz), which has a melting point of 1610°C ., is used as the bulk dielectric material. For process compatibility reasons it may be desirable or necessary to employ other solid materials notably with lower melting temperature (and preferably lower dielectric constant). That is, the solid materials used should be capable of being annealed at a temperature that does not unduly interfere or compromise existing integrated circuit structures.

[0057] SiO_2 has been widely used in microelectronics technology as an inter-layer dielectric, as trench isolation and as passivation between active silicon device regions and interconnects. In microelectronics technology, metal contacts, via and interconnects are fabricated after device processing in silicon, while device isolation regions are fabricated prior to device processing. The processing temperature for contacts and interconnects is required to be low enough not to significantly alter impurity profiles in silicon. Corresponding thermal budgets allowed must be below 1000°C . for time periods

less than a minute, with appropriate compatibility with interconnect metallurgy. An example of such an SiO_2 -based dielectric is the $\{\text{K}_2\text{O}-\text{Al}_2\text{O}_3-4\text{SiO}_2\}$ leucite- SiO_2 binary system.

[0058] FIG. 13 illustrates the binary system $\text{K}_2\text{O}-\text{Al}_2\text{O}_3-4\text{SiO}_2$ (leucite)- SiO_2 . FIG. 13 shows a phase diagram and associated low temperature eutectic at ~55% SiO_2 concentration. In one embodiment, such a dielectric is sputter-deposited with Tungsten metallurgy as studs and as first and second levels of interconnects. In one embodiment, the dielectric is applied earlier in the process for device isolation. In these applications, the electric deposition is followed by the creation of an appropriate array of cylindrical holes into the dielectric. These cylindrical holes are transformed to an empty space, such as empty spheres, pipes or plates through an annealing process.

[0059] One embodiment uses laser pulse annealing to an appropriate temperature close to the melting point of the dielectric, thus achieving a desired empty space filling factor (porosity) and low k value. In various embodiments, tungsten interconnect technology is employed by standard damascene or metal inlaid process.

[0060] Creating voids in an isolation regions reduces parasitic inter-diffusion capacitance and lateral noise propagation within silicon as well as parasitic line to substrate capacitance. Creating voids within the inter-layer dielectric reduces parasitic gate-to-diffusion, line-to-diffusion and substrate capacitance components as well as inter-level and intra-level line to line capacitance. Benefits in microelectronic chip design include: parasitic bitline capacitance reduction; sense-amp signal improvement in array designs, such as DRAM, SRAM, NVRAM and the like; improved random logic cell designs that result in improved density speed and power; and improved analog and digital design integration within the chip by reducing noise propagation.

[0061] FIG. 14 illustrates a phase equilibrium diagram of the ternary system $\text{Na}_2-\text{CaO}-\text{SiO}_2$ showing boundary curves and tie-lines. FIG. 15 illustrates a phase equilibrium diagram of ternary system $\text{Na}_2-\text{CaO}-\text{SiO}_2$ showing isotherms. In one embodiment, the dielectric is a multi-component $\text{Na}_2\text{O}-\text{CaO}-\text{SiO}_2$ glass. In one embodiment, the dielectric is a ternary eutectic composition of the glass. The lowest-melting eutectic of soda (Na_2O) and silica (SiO_2) is at 793°C . and of soda, lime and silica is at 725°C . These are shown in the ternary diagrams of FIGS. 14 and 15. In choosing a glass composition several factors are considered. One factor is whether the glass forms a suitable insulator. Another factor is whether the composition is stable during the formation of the empty spaces. As such, it is desirable to use glass compositions which are thermodynamically invariant.

[0062] In one embodiment, the dielectric includes organic polymers such as polytetrafluoroethylene (Teflon®). Another method for producing porous polymers for integrated circuit applications is discussed by Farrar in U.S. Pat. No. 6,077,792 entitled "Method of Forming Foamed Polymeric Material for an Integrated Circuit." In one embodiment, the dielectric includes lead acetate with a melting point of 280°C . and a dielectric constant (k) of 2.6.

[0063] The figures presented and described in detail above are similarly useful in describing the method aspects of the present subject matter. The methods described below are nonexclusive as other methods may be understood from the specification and the figures described above. One aspect provides a method for forming a wide variety of insulators in

semiconductor applications, such as interconnect dielectrics, and other applications that require or desire an insulator with a low dielectric constant.

[0064] FIG. 16 illustrates one embodiment for forming a integrated circuit. According to this embodiment, device isolation regions are formed at 1610, and one or more devices are formed at 1612. An inter-layer dielectric over the devices is formed at 1614. At 1616, a metal level is formed over the inter-layer dielectric and is appropriately connected or coupled to the devices. One method for depositing a metal pattern is the dual damascene process. Other methods includes the single damascene or subtractive etch metal process. It is determined at 1618 whether another metal level is to be formed. If it is determined that another metal level is to be formed, then the process returns to 1614 to form another inter-layer dielectric and to form a metal level over the dielectric at 1616 with the appropriate connections to the devices. If it is determined at 1618 that another metal level is not to be formed, then the process terminates. This process can be forming another inter-layer dielectric and forming another metal level can be repeated as many times as necessary to produce the required number of metal levels. It is noted that the dielectric material is chosen that has an appropriate annealing temperature to perform the surface transformation process without damaging other parts of the integrated circuit. Different dielectric materials are capable of being used in different parts of the integrated circuit, as desired or required by the application.

[0065] FIG. 17 illustrates one embodiment for forming a low-k insulator for device isolation regions and/or inter-layer dielectrics, shown previously at 1610 and 1614 in FIG. 16. According to one embodiment, a low-k dielectric is deposited at 1720. Holes are formed in the low-k dielectric at 1722. At 1724, the low-k dielectric material is annealed to cause surface transformation. The result of the surface transformation is that the holes that were previously formed in the low-k dielectric are transformed into empty spaces under the surface of the dielectric. These empty spaces lower the effective dielectric constant. Furthermore, the use of the surface transformation technique allows the spaces to be arranged in such a manner as to maximize the amount of void space in the dielectric to minimize the effective dielectric constant.

[0066] It is noted that the formation of the holes in the dielectric, as represented by element 1722, and/or the annealing of the dielectric, as represented by the element 1724, can be performed either before or after the metal level is formed on the low-k dielectric. For example, upon completion of the metal level, an appropriate resist layer is applied and imaged with a series of holes where the hole diameter is at least one half or less of the line to line spacing. Again, a goal is to pack as much air in the dielectric volume because increasing the filling factor (f) of air decreases the effective dielectric constant (k_{eff}) of the dielectric volume. In one embodiment of the present invention, the diameter of the voids within the dielectric volume ranges from 1 micron to 0.2 micron.

[0067] It is possible to define the pattern using direct write e-beam lithography, but this is an expensive and time consuming process. A dense pattern of holes is all that is required to reduce the dielectric constant and the associated capacitive loading effects. Various techniques are available to form the holes in the solid material. One technique is imprint lithography. It may be desired to imprint the mask twice with an random offset of the mask between the printings in order to achieve a high density of holes. Another technique is to form

a stencil using a method described by Asoh et al. (H. Asoh et al., "Fabrication of Ideally Ordered Anodic Porous Alumina with 3 nm Hole Periodicity Using Sulfuric Acid", J. Vac. Technol., B 19(2), Mar./Apr. 2001, pp. 569-572) by first producing a metal mask that can be used repeatedly.

[0068] Continuing with the example, once the insulator has been patterned and holes are etched, the surface is heated rapidly to a temperature near the melting point of the insulator and the surface transformation of cylindrical holes to buried empty spaces takes place. The heating is accomplished by using a pulsed incoherent light or laser source that is applied for a few microseconds to a few milliseconds, thereby only heating the uppermost layer of the wafer. The wafer is rapidly cooled after the heat source is extinguished by the large thermal mass of the wafer.

[0069] FIG. 18 is a simplified block diagram of a high-level organization of an electronic system according to the teachings of the present invention. The electronic system **1800** has functional elements, including a processor or arithmetic/logic unit (ALU) **1802**, a control unit **1804**, a memory device unit **1806** and an input/output (I/O) device **1808**. Generally such an electronic system **1800** will have a native set of instructions that specify operations to be performed on data by the processor **1802** and other interactions between the processor **1802**, the memory device unit **1806** and the I/O devices **1808**. The control unit **1804** coordinates all operations of the processor **1802**, the memory device **1806** and the I/O devices **1808** by continuously cycling through a set of operations that cause instructions to be fetched from the memory device **1806** and executed. The processor **1802** and memory device **1804**, for example, are formed as integrated circuits with a low-k dielectric material according to the teachings of the present invention, thus lowering the RC time delay and improving the performance of the integrated circuits and the overall electronic system.

CONCLUSION

[0070] The present subject matter improves integrated circuit performance by reducing the RC time constant of interconnects. The present subject matter provides a low-k dielectric insulator of greater uniformity and dimensional stability for advanced integrated circuits. The low-k dielectric insulator of the present invention includes empty spaces controllably formed using surface transformation. Forming low dielectric constant materials by incorporating surface transformed empty spaces enables greater control of low-k dielectric properties while avoiding stress and cracking problems which are found in Xerogels and Aerogels.

[0071] Although specific embodiments have been illustrated and described herein, it will be appreciated by those of ordinary skill in the art that any arrangement which is calculated to achieve the same purpose may be substituted for the specific embodiment shown. This application is intended to cover any adaptations or variations of the present invention. It is to be understood that the above description is intended to be illustrative, and not restrictive. Combinations of the above embodiments, and other embodiments will be apparent to those of skill in the art upon reviewing the above description. The scope of the invention includes any other applications in which the above structures and fabrication methods are used. The scope of the invention should be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

What is claimed is:

1. A structure, comprising:
 - an insulator structure of an insulator material; and
 - the insulator structure including an arrangement of a plurality of voids having a predetermined void-to-void spacing, wherein each void has a shape and size formed through a surface transformation process, wherein the surface transformation process includes:
 - forming holes with predetermined dimensions and spacing through a surface of the insulator structure; and
 - annealing the insulator structure to transform the holes through the surface of the insulator structure into the arrangement of the voids with the predetermined void-to-void spacing, wherein the void-to-void spacing and the shape and size of each void is controlled by the predetermined dimensions and spacing of the holes,
- wherein the arrangement of at least one void within the insulator structure lowers an effective dielectric constant of the insulator structure.
2. The structure of claim 1, wherein the insulator material is a low-k insulator material.
3. The structure of claim 2, wherein the insulator material includes silicon.
4. The structure of claim 2, wherein the insulator material includes a multi-component composition.
5. The structure of claim 2, wherein the insulator material includes a eutectic multi-component composition.
6. The structure of claim 1, wherein the insulator material has a low annealing temperature.
7. The structure of claim 6, wherein the insulator material includes lead acetate.
8. The structure of claim 6, wherein the insulator material includes a eutectic multi-component composition.
9. The structure of claim 1, wherein the plurality of voids includes a plate-shaped void.
10. The structure of claim 9, wherein the plurality of voids includes a stack of a plate-shaped voids.
11. The structure of claim 1, wherein the plurality of voids includes at least one pipe-shaped void.
12. A structure, comprising:
 - an insulator structure of a low-k insulator material; and
 - the insulator structure including an arrangement of a plurality of sphere-shaped voids having a predetermined void-to-void spacing, wherein each void has a shape and size formed through a surface transformation process, wherein the surface transformation process includes:
 - forming holes with predetermined dimensions and spacing through a surface of the insulator structure; and
 - annealing the insulator structure to transform the holes through the surface of the insulator structure into the arrangement of the voids with the predetermined void-to-void spacing, wherein the void-to-void spacing and the shape and size of each void is controlled by the predetermined dimensions and spacing of the holes,
- wherein the precisely-determined arrangement of at least one void within the solid structure lowers an effective dielectric constant of the insulator structure.
13. The structure of claim 12, wherein the arrangement of the plurality of sphere-shaped voids includes a close-packed structure of empty spheres.

14. The structure of claim **12**, wherein at least one of the plurality of sphere-shaped voids has a diameter of approximately 1 micron.

15. The structure of claim **12**, wherein at least one of the plurality of sphere-shaped voids has a diameter of approximately 0.2 micron.

16. An electronic system, comprising:

a processor; and

a memory coupled to the processor,

wherein the processor and the memory are formed as at least one integrated circuit, including:

a plurality of devices;

at least one metal level operatively coupled to the plurality of devices; and

an insulator structure of an insulator material between the plurality of devices and the at least one metal level, the insulator structure including an arrangement of a plurality of voids having a predetermined void-to-void spacing, wherein each void has a shape and size formed through a surface transformation process, wherein the surface transformation process includes:

forming holes with predetermined dimensions and spacing through a surface of the insulator structure; and
annealing the insulator structure to transform the holes through the surface of the insulator structure into the arrangement of the voids with the predetermined

void-to-void spacing, wherein the void-to-void spacing and the shape and size of each void is controlled by the predetermined dimensions and spacing of the holes,

wherein the arrangement of the plurality of voids within the insulator structure lowers an effective dielectric constant of the insulator structure and improves the performance of the processor and the memory.

17. The electronic system of claim **16**, wherein the insulator material is a low-k insulator material.

18. The electronic system of claim **17**, wherein the insulator material includes silicon.

19. The electronic system of claim **17**, wherein the insulator material includes a multi-component composition.

20. The electronic system of claim **16**, wherein the insulator material includes a eutectic multi-component composition.

21. The electronic system of claim **16**, wherein the insulator material includes a material having a low melting temperature such that the insulator material is capable of being annealed at a low annealing temperature.

22. The electronic system of claim **16**, wherein the arrangement of the plurality of voids includes a close-packed structure.
