It has been found that the compounds of general formula I and I' as well as individual isomers, racemic or non-racemic mixtures thereof (hereinafter: Active Compounds) are selective monoamine oxidase B inhibitors.

Monoamine oxidase (MAO, EC 1.4.3.4) is a flavin-containing enzyme responsible for the oxidative deamination of endogenous monoamine neurotransmitters such as dopamine, serotonin, adrenaline, or noradrenaline, and trace amines, e.g. phenylethyl-amine, as well as a number of amine xenobiotics. The enzyme exists in two forms, MAO-A and MAO-B, encoded by different genes [Bach et al., Proc. Natl. Acad. Sci. USA 85:4934-4938 (1988)] and differing in tissue distribution, structure and substrate specificity. MAO-A has higher affinity for serotonin, octopamine, adrenaline, and noradrenaline; whereas the natural substrates for MAO-B are phenylethylamine and tyramine. Dopamine is thought to be oxidised by both isoforms. MAO-B is widely distributed in several organs including brain [Cesura and Pletscher, Prog. Drug Research 38:171-297 (1992)]. Brain MAO-B activity appears to increase with age. This increase has been attributed to the gliosis associated with aging [Fowler et al., J. Neural. Transm. 49:1-20 (1980)]. Additionally, MAO-B activity is significantly higher in the brains of patients with Alzheimer’s disease [Dostert et al., Biochem. Pharmacol. 38:555-561 (1989)] and it has been found to be highly expressed in astrocytes around senile plaques [Saura et al., Neuroscience 70:755-774 (1994)]. In this context, since oxidative deamination of primary monoamines by MAO produces NH$_3$, aldehydes and H$_2$O$_2$, agents with established or potential toxicity, it is suggested that there is a rationale for the use of selective MAO-B inhibitors for the treatment of dementia and Parkinson’s disease. Inhibition of MAO-B causes a reduction in the enzymatic inactivation of dopamine and thus prolongation of the availability of the neurotransmitter in dopaminergic neurons. The degeneration processes associated with age and Alzheimer’s and Parkinson’s diseases may also be attributed to oxidative stress due to increased MAO activity and consequent increased formation of H$_2$O$_2$ by MAO-B. Therefore, MAO-B inhibitors may act by both reducing the formation of oxygen radicals and elevating the levels of monoamines in the brain.

Given the implication of MAO-B in the neurological disorders mentioned above, there is considerable interest to obtain potent and selective inhibitors that would permit control over this enzymatic activity. The pharmacology of some known MAO-B inhibitors is for
example discussed by Bentué-Ferrer et al. [CNS Drugs 6:217-236 (1996)]. Whereas a major limitation of irreversible and non-selective MAO inhibitor activity is the need to observe dietary precautions due to the risk of inducing a hypertensive crisis when dietary tyramine is ingested, as well as the potential for interactions with other medications [Gardner et al., J. Clin. Psychiatry 57:99-104 (1996)], these adverse events are of less concern with reversible and selective MAO inhibitors, in particular of MAO-B. Thus, there is a need for MAO-B inhibitors with a high selectivity and without the adverse side-effects typical of irreversible MAO inhibitors with low selectivity for the enzyme.

In another embodiment the present invention provides a process for the preparation of 
compounds of formula I comprising reacting a compound of formula II
wherein $R^1$, $R^{1.1}$, $R^{1.2}$, $R^{21}$, $R^{22}$, $R^{23}$, $R^4$, $-X-Y-$ and $Q$ have the above meanings and $R^*$ is hydrogen or $(C_1-C_6)$-alkyl

(a) with an amine of formula $H_2N-CH_3$, obtaining compounds of formula I wherein $R^3$ is $-C(O)N(H)CH_3$; or

(b) reducing a compound of formula II to a compound of formula III

wherein $R^1$, $R^{1.1}$, $R^{1.2}$, $R^{21}$, $R^{22}$, $R^{23}$, $R^4$, $-X-Y-$ and $Q$ have the above meanings and reacting this compound with a cyanide salt, obtaining compounds of formula I wherein $R^3$ is $CH_2CN$.

The compounds of general formula $I^*$ can be manufactured by reacting a compound of formula $II^*$

wherein $R^1$, $R^{21}$, $R^{22}$, $R^{23}$, $R^{24}$ and $n$ have the above meanings with an amine of formula $H_2N-R^5$, wherein $R^5$ has the above meaning, to obtain a compound of formula $Ia^*$

or, alternatively, reducing a compound of formula $II^*$ to the corresponding alcohol of formula $III^*$
and reacting this compound with a cyanide salt to obtain a compound of formula Ib*

or, alternatively,

reacting a compound of formula IV*

wherein X is halogen, with a cyanide salt, to obtain a compound of formula Ic*

In accordance with the present invention, scheme 1 shows the main routes to compounds of the formula I wherein \( R^3 \) is \(-\text{C}(\text{O})\text{N(H)CH}_3\), i.e. compounds of formula I**. The reaction of the intermediates IV and IVa with itaconic acid V is preferentially done neat at temperatures between 80°C and 200°C. Compounds of formula IIa and IVa are then transformed to esters of formula IIIb and VIa by methods known per se. Compounds of formula VIa can then be alkylated by Williamson-ether synthesis using optionally substituted benzylic halides, tosylates, mesylates or triflates. Bases used can be, e.g., alcohohates or carbonates, like e.g. sodium, potassium or cesium carbonate. Examples for solvents are lower alcohols, acetonitrile or lower ketones. The temperature may be, e.g. in the range of from 20°C to reflux temperature. Another approach is the Mitsunobu-coupling of optionally substituted benzylic alcohols with phenol VIa. The reaction may be done as usual in inert solvents like, e.g., diethyl ether or tetrahydrofurane, using dialkyl-azo-dicarboxylates in the presence of phosphines (e.g. tributyl- or triphenyl-phosphine).
The hydrolysis of compounds of formula VIa can be performed by methods known per se like hydrolysis under acidic conditions, e.g. with hydrochloric acid, or basic conditions, e.g. lithium, sodium- or potassium hydroxide in mixtures of alcohols and water as the solvent.

In compounds of formula I** or IIb where –X–Y- has the meaning of –CH₂–O–, the optionally substituted benzyl residue can function as a transient group which can be cleaved by hydrogenolysis. The resulting phenols VIa and Vlb can then be re-alkylated by a different benzyl group under the aforementioned conditions. As known to those skilled in the art, this process is only possible on condition that the other substituents are stable under the aforementioned reaction conditions for the hydrogenolysis and alkylation reaction.

Scheme 1
Amides of formula I** or VIIb can be obtained by aminolysis of esters of formula IIb or VIa with amines of formula R^5-NH_2 at a temperature in the range of from room temperature (RT) and 120°C, e.g. in sealed tubes using solvents inert under these conditions, like e.g. dimethoxyethane, dioxane, or methanol. Alternatively, acids of formula IIa may be transformed into compounds of formula I** using standard procedures. They can be activated via, e.g., acid chloride or mixed anhydride. Especially for the preparation of enantiopure derivatives, condensation reagents like carbodiimides, e.g. dicyclohexyl-carbodiimide, or benzotriazol derivatives, e.g. O-(benzotriazol-1-yl)-N,N,N',N'-tetramethyluronium-hexafluorophosphate (HBTU) may be applied.

wherein LG is a leaving group, e.g. halogen, e.g. Cl, Br or I, or SnR_3 or B(OH)_2, and R^3' is -CONHR^5 or -CH_2CN or alkoxy carbonyl.

In accordance with the present invention, a possibility to prepare the intermediates of general formula IV, wherein \(-X-Y-\) is \(-\text{CH}_2\text{-O}-\), i.e. a compound of formula IVb, is shown in scheme 3: The intermediates of formula XII are accessible through nucleophilic substitution of aromatic nitro compounds of formula XI containing p-substituted leaving groups with benzylic alcohols of formula X. Leaving groups in para-position can be, e.g., halogens (F, Cl, Br, I), tosylates, mesylates or triflates. These substitution reactions can be conducted neat or in inert solvents like, e.g., toluene or xylene. The reaction temperature may be in the range of from 50°C to 150°C. Alternatively, compounds of formula XII can be prepared by Williamson-ether synthesis, starting from p-nitrophenols of formula XIV and benzylic halides, tosylates, mesylates or triflates of formula XIII. Bases used can be, e.g., alcohohates or carbonates (sodium, potassium or cesium carbonate). Examples for solvents are lower alcohols, acetonitrile or lower ketones. The temperature may be in the
range of from 20°C to reflux temperature. Another approach is the Mitsunobu-coupling of benzyl alcohol with \( p \)-nitrophenols of formula XIV. The reaction is done as usual in inert solvents like for example diethyl ether or tetrahydrofurane, using dialkyl azodicarboxylates in the presence of phosphites like e.g. tributyl- or triphenyl-phosphine.

The key intermediates of formula XII are reduced to the amino compounds of formula IVb using catalytic hydrogenation, like e.g. using platinum on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofurane. An alternative is the reduction of the nitro-group by metals like iron, tin, or zinc in acidic media, like diluted hydrochloric acid or acetic acid. Metals can also be replaced by metal salts like e.g. tin-(II)-chloride.

wherein LG is a leaving group, e.g. halogen, OTf, etc., and \( \text{Y} \) is a leaving group, e.g. halogen, OTf, etc. or OH (for Mitsunobu-coupling).

In accordance with the present invention, a possibility to prepare the intermediates of formula IVd (wherein \(-X-\text{Y}=-\text{CH}==\text{CH}_2\)) and IVc (wherein \(-X-\text{Y}=-\text{CH}_2==\text{CH}_2\)) is shown in scheme 4: The intermediates of formula XVII are accessible by olefination reaction of optionally substituted aromatic aldehydes of formula XV with dialkyl (4-nitro-benzyl)-phosphonates of formula XVI in the presence of a base, like e.g. sodium hydride, yielding the corresponding nitro-olefins of formula XVII.

Scheme 4
The key intermediates of formula XVII can be reduced selectively to the amino-olefins of formula IVd using catalytic hydrogenation like e.g. using platinum on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofuran as the solvent, or, by metals or metal salts, like e.g. tin-(II)-chloride. The amino derivatives of formula IVc can be obtained directly from the nitro derivatives of formula XVII or from the amino-olefins of formula IVd by hydrogenation using palladium on charcoal as the catalyst in lower alcohols, ethyl acetate or tetrahydrofuran as the solvent.

Alternatively, compounds of formula II can be reduced to the intermediate compound of formula III. This may be done by first converting the acids of formula II into their esters (alcohol / acid catalysis) followed by reduction with reagents like sodium borohydride in solvents like tetrahydrofuran at a temperature in the range of from 20°C to 65°C. Activation of the alcohol of formula III via mesylate or triflate and reaction with sodium or potassium cyanide at a temperature in the range of from 40°C to 80°C leads to the desired compounds of formula I wherein R³ is CH₂CN, i.e. nitriles of formula Ib.

Scheme 5
Compounds of general formula I can also exist in optical pure form. Separation into enantiomers can be affected according methods known per se, either at an early stage of the synthesis, e.g. starting with compounds of formula IIa by salt formation with an optically active amine such as, for example, (+)- or (-)-1-phenylethylamine or (+)- or (-)-1-naphthylethylamine and separation of the diastereomeric salts by fractional crystallisation, or by derivatisation with a chiral auxiliary substance such as, for example, (+)- or (-)-2-butanol, (+)- or (-)-1-phenylethanol, or (+)- or (-)-menthol and separation of the diastereomeric products by chromatography and/or crystallisation and subsequent cleavage of the bond to the chiral auxiliary substance; or, on the very last stage, by separation of the enantiomers of formula I by chromatography on a chiral phase. Furthermore, compounds of formula I can also be obtained from enantiopure intermediates obtained by biotransformation, e.g. by hydrolysis of esters of formula VIa by enzymes, such as e.g. cholesterase from Candida cylindracea. In order to determine the absolute configuration of the pyrrolidonone derivative obtained, the pure diastereomeric salts or derivatives can be analysed by conventional spectroscopic methods, e.g. with X-ray spectroscopy on single crystals.

The Active Compounds are, as already mentioned above, monoamine oxidase B inhibitors and can be used for the treatment or prevention of diseases in which MAO-B inhibitors might be beneficial. These include acute and chronic neurological disorders, cognitive disorders and memory deficits. Treatable neurological disorders are for instance traumatic or chronic degenerative processes of the nervous system, such as Alzheimer's disease, other types of dementia, minimal cognitive impairment or Parkinson's disease. Other indications include psychiatric diseases such as depression, anxiety, panic attack, social phobia, schizophrenia, eating and metabolic disorders such as obesity, as well as the prevention and treatment of withdrawal syndromes induced by abuse of alcohol, nicotine and other
addictive drugs. Other treatable indications may be peripheral neuropathy caused by cancer chemotherapy (WO 97/33,572), reward deficiency syndrome (WO 01/34,172), or the treatment of multiple sclerosis (WO 96/40,095), and other neuroinflammatory diseases.

The Active Compounds are especially useful for the treatment and prevention of Alzheimer's disease and senile dementia.

The pharmacological activity of the compounds was tested using the following method:

The cDNAs encoding human MAO-A and MAO-B were transiently transfected into EBNA cells using the procedure described by Schlaeger and Christensen [Cytotechnology 15:1-13 (1998)]. After transfection, cells were homogenised by means of a Polytron homogenizer in 20 mM Tris HCl buffer, pH 8.0, containing 0.5 mM EGTA and 0.5 mM phenylmethanesulfonyl fluoride. Cell membranes were obtained by centrifugation at 45,000 x g and, after two rinsing steps with 20 mM Tris HCl buffer, pH 8.0, containing 0.5 mM EGTA, membranes were eventually re-suspended in the above buffer and aliquots stored at -80°C until use.

MAO-A and MAO-B enzymatic activity was assayed in 96-well-plates using a spectrophotometric assay adapted from the method described by Zhou and Panchuk-Voloshina [Analytical Biochemistry 253:169–174 (1997)]. Briefly, membrane aliquots were incubated in 0.1 M potassium phosphate buffer, pH 7.4, for 30 min at 37°C containing different concentrations of the compounds. After this period, the enzymatic reaction was started by the addition of the MAO substrate tyramine together with 1 U/ml horse-radish peroxidase (Roche Biochemicals) and 80 µM N-acetyl-3,7-dihydroxyphenoxazine (Amplex Red, Molecular Probes). The samples were further incubated for 30 min at 37°C in a final volume of 200 µl and absorbance was then determined at a wavelength of 570 nm using a SpectraMax plate reader (Molecular Devices). Background (non-specific) absorbance was determined in the presence of 10 µM clorgyline for MAO-A or 10 µM L-deprenyl for MAO-B. IC₅₀ values were determined from inhibition curves obtained using nine inhibitor concentrations in duplicate, by fitting data to a four parameter logistic equation using a computer program.

The compounds of the present invention are specific MAO-B inhibitors. The IC₅₀ values of preferred Active Compounds as measured in the assay described above are in the range of 1 µM or less, typically 0.1 µM or less, and ideally 0.02 µM or less.

The Active Compounds can be used as medicaments, e.g. in the form of pharmaceutical preparations. The pharmaceutical preparations can be administered orally, e.g. in the form
of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions. However, the administration can also be effected rectally, e.g. in the form of suppositories, or parenterally, e.g. in the form of injection solutions.

The Active Compounds can be processed with pharmaceutically inert, inorganic or organic carriers for the production of pharmaceutical preparations. Lactose, corn starch or derivatives thereof, talc, stearic acid or its salts and the like can be used, for example, as such carriers for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carriers for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi-solid and liquid polyols and the like; depending on the nature of the active substance no carriers are, however, usually required in the case of soft gelatine capsules. Suitable carriers for the production of solutions and syrups are, for example, water, polyols, sucrose, invert sugar, glucose and the like. Adjuvants, such as alcohols, polyols, glycerol, vegetable oils and the like, can be used for aqueous injection solutions of water-soluble salts of Active Compounds, but as a rule are not necessary. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

In addition, the pharmaceutical preparations can contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They may also contain other therapeutically valuable substances.

As mentioned earlier, medicaments containing an Active Compound and a therapeutically inert excipient are also an object of the present invention, as is a process for the production of such medicaments which comprises bringing one or more Active Compound and, if desired, one or more other therapeutically valuable substances into a galenical dosage form together with one or more therapeutically inert carriers.

The dosage can vary within wide limits and will, of course, be fitted to the individual requirements in each particular case. In general, the effective dosage for oral or parenteral administration is between 0.01-20 mg/kg/day, with a dosage of 0.1-10 mg/kg/day being preferred for all of the indications described. The daily dosage for an adult human being weighing 70 kg accordingly lies between 0.7-1400 mg per day, preferably between 7 and 700 mg per day.

The following examples are provided for illustration of the invention. They should not be considered as limiting the scope of the invention, but merely as being representative thereof. The abbreviation „RT“ means „room temperature“.
Example 1: (RS)-1-[4-(3-Fluoro-benzylxoy)-phenyl]-5-oxo-pyrrolidine-3-carboxylic acid methylamide

a) (RS)-1-(4-Benzylxoy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid
18.8 g (94.4 mmol) 4-benzylxoyaniline are mixed with 12.28 g (94.4 mmol) itaconic acid. The mixture is heated to 130°C. After 20 min the melted material solidifies. The resulting solid is triturated with ethyl acetate to yield 28.26 g (96 %) of a greyish solid. MS: m/e = 311 (M⁺).

b) (RS)-1-(4-Benzylxoy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid methyl ester
7.46 g (24 mmol) (RS)-1-(4-benzylxoy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid is dissolved in a mixture of 40 ml dichloromethane and 7.5 ml methanol. 0.13 ml concentrated sulfuric acid is added and the reaction mixture hold under reflux over night. The solvent is evaporated and the residue triturated with diethyl ether to yield 7.26 g (93%) of a colorless solid (used in the next step without further purification).

After addition of 726 mg palladium 10% on charcoal hydrogenation is performed at RT and normal pressure. After 3 hours, the catalyst is filtered off and the solvent evaporated to yield 6.04 g of crude product (used in the next step without further purification).

d) (RS)-1-[4-(3-Fluoro-benzylxoy)-phenyl]-5-oxo-pyrrolidine-3-carboxylic acid methyl ester

The reaction mixture is heated at 90°C for 5 hours, cooled and poured into water. Extraction with ethyl acetate gives a crude material which is subjected to chromatography (silica gel, n-hexane / ethyl acetate 1:1). This gives 2.10 g (24 %) of a colorless solid. The reaction vessel is tightly stopped and held at 120°C for 48 hours. Water is added and the product extracted with ethyl acetate. Drying and evaporation yields 92 mg (31 %) of a slightly yellowish product. MS: m/e = 343.3 (M+ H)⁺.

In a metallic pan, 257.0 g (2.355 mol) of 4-aminophenol and 301.75 g (2.32 mol) of itaconic acid are mixed in solid form. Under stirring with a metal spatula, the mixture was carefully heated on a heating plate. The temperature was measured by a thermometer. At 60°C, the powder started to become viscous, at 110-120°C it became liquid and the colour turned to dark brown while the rest of solid material was also dissolved. The exothermic reaction started under boiling and, while the temperature raised to 150°C, the reaction mass turned to a beige solid. The sandy product was left to cool down to RT within 1-2 hours. The crude (RS)-1-(4-hydroxyoxy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid was engaged in the next step without further purification or characterisation.

In a 10 l 4-necked flask equipped with a reflux condenser, a thermometer, and a mechanical stirrer, the crude (RS)-1-(4-hydroxyoxy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid is dissolved in a mixture of 5000 ml of methanol, 24 ml of concentrated sulfuric acid and 400 ml of 2,2-dimethoxypropane and stirred under reflux during 2 h. For the working-up, the reaction solution is reduced to half of its volume by distillation, then transferred into a 20 l vessel. Under stirring at 40°C, a mixture of 2500 ml of water/ice (1:1) is added.

Crystallisation started immediately, and, thereupon, the fine white crystals are collected on a filter funnel. They are washed with total 2000 ml of cold water until the filtrate, at the beginning brownish-rose, becomes colourless and neutral. The well pressed and pre-dried product from the filter funnel is dried under reduced pressure to yield 980 g (84% of theory, 2 steps) of the (RS)-1-(4-hydroxyoxy-phenyl)-5-oxo-pyrrolidine-3-carboxylic acid methyl ester as a white solid; MS: m/e = 234 (M+ H)⁺.
