PYRIDO[3,2-E]PYRAZINES, PROCESS FOR PREPARING THE SAME, AND THEIR USE AS
INHIBITORS OF PHOSPHODIESTERASE

FIELD OF THE INVENTION

The invention relates to pyrido[3,2-e]pyrazines, which are inhibitors of phosphodiesterase and useful for treating diseases related to the central nervous system as well as obesity and metabolic disorders.

BACKGROUND

Psychotic disorders, especially schizophrenia, are severe mental disorders which extremely impair daily life. The symptoms of psychosis may be divided into two fractions. In the acute phase, it is predominated by hallucinations and delusions being called the positive symptoms. When the agitated phase abates the so called negative symptoms become obvious. They include cognitive deficits, social phobia, reduced vigilance, indifference and deficits in verbal learning and memory, verbal fluency and motor function.

Although several antipsychotics are available since, the present therapy of psychosis is not satisfactory. The classic antipsychotics, such as haloperidol, with a high affinity to dopamine D2 receptor show extreme side effects, such as extrapyramidal symptoms (=EPS) and do not improve the negative symptoms of schizophrenia so that they do not enable the patient to return to everyday life.

Clozapine which has emerged as a benchmark therapeutic ameliorating positive, negative and cognitive symptoms of schizophrenia and devoid of EPS shows agranulocytosis as a major, potential lethal side-effect (Capuano et al., Curr Med Chem 9: 521-548, 2002). Besides, there is still a high amount of therapy resistant cases (Lindenmayer et al., J Clin Psychiatry 63: 931-935, 2002).

In conclusion, there is still a need for developing new antipsychotics which ameliorate positive, negative and cognitive symptoms of psychosis and have a better side effect profile.

The exact pathomechanism of psychosis is not yet known. A dysfunction of several neurotransmitter systems has been shown. The two major neurotransmitter systems that are involved are the dopaminergic and the glutamatergic system:

Thus, acute psychotic symptoms may be stimulated by dopaminergic drugs (Capuano et al., Curr Med Chem 9: 521-548, 2002) and classical antipsychotics, like haloperidol, have a high affinity to the dopamine D2 receptor (Nyberg et al., Psychopharmacology 162: 37-41, 2002). Animal models based on a hyperactivity of the dopaminergic neurotransmitter system (amphetamine hyperactivity, apomorphine climbing) are used to mimic the positive symptoms of schizophrenia.

Additionally there is growing evidence that the glutamatergic neurotransmitter system plays an important role in the development of schizophrenia (Millan, Prog Neurobiol 70: 83-244, 2005). Thus, NMDA antagonists like phencyclidine and ketamine are able to stimulate schizophrenic
symptoms in humans and rodents (Abi-Saab et al., Pharmacopsychiatry 31 Suppl 2: 104-109, 1998; Lahti et al., Neuropsychopharmacology 25: 455-467, 2001). Acute administration of phencyclidine and MK-801 induce hyperactivity, stereotypies and ataxia in rats mimicking psychotic symptoms. Moreover, in contrast to the dopaminergic models the animal models of psychosis based on NMDA antagonists do not only mimic the positive symptoms but also the negative and cognitive symptoms of psychosis (Abi-Saab et al., Pharmacopsychiatry 31 Suppl 2: 104-109, 1998; Jentsch and Roth, Neuropsychopharmacology 20: 201-225, 1999). Thus, NMDA antagonists, additionally induce cognitive deficits and social interaction deficits.

Eleven families of phosphodiesterases have been identified in mammals so far (Essayan, J Allergy Clin Immunol 108: 671-680, 2001). The role of PDEs in the cell signal cascade is to inactivate the cyclic nucleotides cAMP and/or cGMP (Soderling and Beavo, Proc Natl Acad USA 96(12):7071-7076, 2000). Since cAMP and cGMP are important second messenger in the signal cascade of G-protein-coupled receptors PDEs are involved in a broad range of physiological mechanisms playing a role in the homeostasis of the organism.

The PDE families differ in their substrate specificity for the cyclic nucleotides, their mechanism of regulation and their sensitivity to inhibitors. Moreover, they are differentially localized in the organism, among the cells of an organ and even within the cells. These differences lead to a differentiated involvement of the PDE families in the various physiological functions.

PDEIO (PDEIOA) is primarily expressed in the brain and here in the nucleus accumbens and the caudate putamen. Areas with moderate expression are the thalamus, hippocampus, frontal cortex and olfactory tubercle (Menniti et al., William Harvey Research Conference, Porto, December 6th - 8th, 2001). All these brain areas are described to participate in the pathomechanism of schizophrenia (Lapiz et al., Neurosci Behav Physiol 33: 13-29, 2003) so that the location of the enzyme indicates a predominate role in the pathomechanism of psychosis.

In the striatum PDEI OA is predominately found in the medium spiny neurons and they are primarily associated to the postsynaptic membranes of these neurons (Xie et al., Neuroscience 139: 597-607, 2006). By this location PDEIOA may have an important influence on the signal cascade induced by dopaminergic and glutamatergic input on the medium spiny neurons two neurotransmitter systems playing a predominate role in the pathomechanism of psychosis.

Phosphodiesterase (PDE) 10A, in particular, hydrolyses both cAMP and cGMP having a higher affinity for cAMP (K_m = 0.05 μM) than for cGMP (K_m =3 μM) (Soderling et al., Curr. Opin. Cell Biol 12: 174-179, 1999).

Psychotic patients have been shown to have a dysfunction of cGMP and cAMP levels and its downstream substrates (Kaiya, Prostaglandins Leukot Essent Fatty Acids 46: 33-38, 1992; Muly, Psychopharmacol Bull 36: 92-105, 2002; Garver et al., Life Sci 31: 1987-1992, 1982). Additionally, haloperidol treatment has been associated with increased cAMP and cGMP levels in rats and patients, respectively (Leveque et al., J Neurosci 20: 401 1-4020, 2000; Gattaz et al., Biol Psychiatry 19: 1229-
As PDElOA hydrolyses both cAMP and cGMP (Kotera et al., Biochem Biophys Res
Commun 261: 551-557, 1999), an inhibition of PDElOA would also induce an increase of cAMP and
cGMP and thereby have a similar effect on cyclic nucleotide levels as haloperidol.

The antipsychotic potential of PDElOA inhibitors is further supported by studies of
Kostowski et al. (Pharmacol Biochem Behav 5: 15-17, 1976) who showed that papaverine, a
moderate selective PDElOA inhibitor, reduces apomorphine-induced stereotypies in rats, an animal
model of psychosis, and increases haloperidol-induced catalepsy in rats while concurrently reducing
dopamine concentration in rat brain, activities that are also seen with classical antipsychotics. This is
further supported by a patent application establishing papaverine as a PDElOA inhibitor for the

In addition to classical antipsychotics which mainly ameliorate the positive symptoms of
psychosis, PDElOA also bears the potential to improve the negative and cognitive symptoms of
psychosis.

Focusing on the dopaminergic input on the medium spiny neurons, PDElOA inhibitors by up-
regulating cAMP and cGMP levels act as D1 agonists and D2 antagonists because the activation of
Gs-protein coupled dopamine D1 receptor increases intracellular cAMP, whereas the activation of the
Gi-protein coupled dopamine D2 receptor decreases intracellular cAMP levels through inhibition of
adenylyl cyclase activity (Mutschler et al., Mutschler Arzneimittelwirkungen. 8th ed. Stuttgart:

Elevated intracellular cAMP levels mediated by D1 receptor signalling seems to modulate a
series of neuronal processes responsible for working memory in the prefrontal cortex (Sawaguchi,
Parkinsonism Relat Disord 7: 9-19, 2000), and it is reported that D1 receptor activation may improve
working memory deficits in schizophrenic patients (Castner et al., Science 287: 2020-2022, 2000).
Thus, it seems likely that a further enhancement of this pathway might also improve the cognitive
symptoms of schizophrenia.

Further indication of an effect of PDElOA inhibition on negative symptoms of psychosis was
given by Rodefer et al. (Eur.J Neurosci 21: 1070-1076, 2005) who could show that papaverine
reverses attentional set-shifting deficits induced by subchronic administration of phencyclidine, an
NMDA antagonist, in rats. Attentional deficits including an impairment of shifting attention to novel
stimuli belongs to the negative symptoms of schizophrenia. In the study the attentional deficits were
induced by administering phencyclidine for 7 days followed by a washout period. The PDElOA
inhibitor papaverine was able to reverse the enduring deficits induced by the subchronic treatment.

The synthesis of imidazo[1,5-a]pyrido[3,2-e]pyrazinones and some medical uses are well
described in patents and the literature.

The documents EP 0 400 583 and US 5,055,465 from Berlex Laboratories, Inc. report a group
of imidazoquinoxalinones, their aza analogs and a process for their preparation. These compounds
have been found to have inodilatory, vasodilatory and yenodilatory effects. The therapeutic activity is based on the inhibition of phosphodiesterase 3 (PDE3).

WO 00/43392 reports pyrido[3,2-e]pyrazinones and a process for their preparation. These compounds are described to have anti-asthmatic and anti-allergic properties. Examples of this invention are inhibitors of PDE4 and PDE5.

WO 00/43392 reports pyrido[3,2-e]pyrazinones which are inhibitors of PDE3 and PDE5 for the therapy of erectile dysfunction, heart failure, pulmonic hypertonia and vascular diseases which are accompanied by insufficient blood supply.

Another group of pyrido[3,2-e]pyrazinones, reported in WO 01/68097 are inhibitors of PDE5 and can be used for the treatment of erectile dysfunction.

WO 92/22552 refers to imidazo[1,5-a]quinoxalines which are generally substituted at position 3 with a carboxylic acid group and derivatives thereof. These compounds are described to be useful as anxiolytic and sedative-hypnotic agents.

In contrast, only a limited number of imidazo[1,5-a]pyrido[3,2-e]pyrazines and their medical use are already published.

Further PDE10 inhibitors are reported in U.S. Application Serial Nos. 11/753,207 and 11/753,260.

Particular preference is given to using oral, parenteral, e.g. intravenous or intramuscular, intranasal, e.g. dry powder or sublingual preparations of the compounds according to the invention. The customary galenic preparation forms, such as tablets, sugar-coated tablets, capsules, dispersible powders, granulates, aqueous solutions, alcohol-containing aqueous solutions, aqueous or oily suspensions, syrups, juices or drops, are used.

Solid medicinal forms can comprise inert components and carrier substances, such as calcium carbonate, calcium phosphate, sodium phosphate, lactose, starch, mannitol, alginates, gelatine, guar gum, magnesium stearate, aluminium stearate, methyl cellulose, talc, highly dispersed silicic acids, silicone oil, higher molecular weight fatty acids, (such as stearic acid), gelatine, agar agar or vegetable or animal fats and oils, or solid high molecular weight polymers (such as polyethylene glycol);
preparations which are suitable for oral administration can comprise additional flavourings and/or sweetening agents, if desired.

Liquid medicinal forms can be sterilized and/or, where appropriate, comprise auxiliary substances, such as preservatives, stabilizers, wetting agents, penetrating agents, emulsifiers, spreading agents, solubilizers, salts, sugars or sugar alcohols for regulating the osmotic pressure or for buffering, and/or viscosity regulators.

Examples of such additives are tartrate and citrate buffers, ethanol and sequestering agents (such as ethylenediaminetetraacetic acid and its nontoxic salts). High molecular weight polymers, such as liquid polyethylene oxides, microcrystalline celluloses, carboxymethyl celluloses, polyvinylpyrrolidones, dextrins or gelatine, are suitable for regulating the viscosity. Examples of solid carrier substances are starch, lactose, mannitol, methyl cellulose, talc, highly dispersed silicic acids, high molecular weight fatty acids (such as stearic acid), gelatine, agar agar, calcium phosphate, magnesium stearate, animal and vegetable fats, and solid high molecular weight polymers, such as polyethylene glycol.

Oily suspensions for parenteral or topical applications can be vegetable synthetic or semisynthetic oils, such as liquid fatty acid esters having in each case from 8 to 22 C atoms in the fatty acid chains, for example palmitic acid, lauric acid, tridecanoic acid, margaric acid, stearic acid, arachidic acid, myristic acid, behenic acid, pentadecanoic acid, linoleic acid, elaidic acid, brasic acid, erucic acid or oleic acid, which are esterified with monohydric to trihydric alcohols having from 1 to 6 C atoms, such as methanol, ethanol, propanol, butanol, pentanol or their isomers, glycol or glycerol. Examples of such fatty acid esters are commercially available miglyols, isopropyl myristate, isopropyl palmitate, isopropyl stearate, PEG 6-capric acid, caprylic/capric acid esters of saturated fatty alcohols, polyoxyethylene glycerol trioleates, ethyl oleate, waxy fatty acid esters, such as artificial ducktail gland fat, coconut fatty acid isopropyl ester, oleyl oleate, decyl oleate, ethyl lactate, dibutyl phthalate, diisopropyl adipate, polyol fatty acid esters, inter alia. Silicone oils of differing viscosity, or fatty alcohols, such as isotridecyl alcohol, 2-octyldecanol, cetylstearyl alcohol or oleyl alcohol, or fatty acids, such as oleic acid, are also suitable. It is furthermore possible to use vegetable oils, such as castor oil, almond oil, olive oil, sesame oil, cotton seed oil, groundnut oil or soybean oil.

Suitable solvents, gelatinizing agents and solubilizers are water or watermiscible solvents.

Examples of suitable substances are alcohols, such as ethanol or isopropyl alcohol, benzyl alcohol, 2-octyldecanol, polyethylene glycols, phthalates, adipates, propylene glycol, glycerol, di- or tripropylene glycol, waxes, methyl cellulose, cellosolve, esters, morpholines, dioxane, dimethyl sulphoxide, dimethylformamide, tetrahydrofuran, cyclohexanone, etc.

Cellulose ethers which can dissolve or swell both in water or in organic solvents, such as hydroxypropylmethyl cellulose, methyl cellulose or ethyl cellulose, or soluble starches, can be used as film-forming agents.
Mixtures of gelatinizing agents and film-forming agents are also perfectly possible. In this case, use is made, in particular, of ionic macromolecules such as sodium carboxymethyl cellulose, polyacrylic acid, polymethacrylic acid and their salts, sodium amylopectin semiglycolate, alginic acid or propylene glycol alginate as the sodium salt, gum arabic, xanthan gum, guar gum or carrageenan. The following can be used as additional formulation aids: glycerol, paraffin of differing viscosity, triethanolamine, collagen, allantoin and novantisolic acid. Use of surfactants, emulsifiers or wetting agents, for example of Na laurel sulphate, fatty alcohol ether sulphates, di-Na-N-lauryl-β-iminodipropionate, polyethoxylated castor oil or sorbitan monooleate, sorbitan monostearate, polysorbates (e.g. Tween), cetyl alcohol, lecithin, glycerol monostearate, polyoxyethylene stearate, alkylphenol polyglycol ethers, cetyltrimethylammonium chloride or mono-/dialkylpolyglycol ether orthophosphoric acid monoethanolamine salts can also be required for the formulation. Stabilizers, such as montmorillonites or colloidal silicic acids, for stabilizing emulsions or preventing the breakdown of active substances such as antioxidants, for example tocopherols or butylhydroxyanisole, or preservatives, such as p-hydroxybenzoic acid esters, can likewise be used for preparing the desired formulations.

Preparations for parenteral administration can be present in separate dose unit forms, such as ampoules or vials. Use is preferably made of solutions of the active compound, preferably aqueous solution and, in particular, isotonic solutions and also suspensions. These injection forms can be made available as ready-to-use preparations or only be prepared directly before use, by mixing the active compound, for example the lyophilisate, where appropriate containing other solid carrier substances, with the desired solvent or suspending agent.

Intranasal preparations can be present as aqueous or oily solutions or as aqueous or oily suspensions. They can also be present as lyophilisates which are prepared before use using the suitable solvent or suspending agent.

Inhalable preparations can present as powders, solutions or suspensions. Preferably, inhalable preparations are in the form of powders, e.g. as a mixture of the active ingredient with a suitable formulation aid such as lactose.

The preparations are produced, aliquoted and sealed under the customary antimicrobial and aseptic conditions. As indicated above, the compounds of the invention may be administered as a combination therapy with further active agents, e.g. therapeutically active compounds useful in the treatment of central nervous system disorders.

These further compounds may be PDE 10 inhibitors or compounds which have an activity which is not based on PDE 10 inhibition such as dopamine D2 receptor modulating agents or NMDA modulating agents.

For a combination therapy, the active ingredients may be formulated as compositions containing several active ingredients in a single dose form and/or as kits containing individual active
ingredients in separate dose forms. The active ingredients used in combination therapy may be
coadministered or administered separately.

Compounds currently used to treat schizophrenia have been associated with several undesirable side effects. These side effects include weight gain, hyperprolactinemia, elevated triglyceride levels, metabolic syndrome (markers: diabetes, hyperlipidemia, hypertension, and obesity), glucose abnormalities (such as hyperglycemia, elevated blood glucose and impaired glucose tolerance), and the exhibition of extrapyramidal symptoms. The weight gain observed with conventional atypical antipsychotics, such as risperidone and olanzapine, has been associated with an increased risk of cardiovascular disease and diabetes mellitus.

In contrast, compounds of the present invention are useful in treating schizophrenia to effect a clinically relevant improvement such as reduction of a PANSS total score in a patient, while maintaining body weight, maintaining or improving glucose levels and/or tolerance, maintaining and/or improving triglycerides levels and/or total cholesterol levels and/or maintaining an EPS profile similar to baseline measurements before administration.

The PDE10 inhibitors of the invention are further useful in the prevention and treatment of obesity, type 2 diabetes (non-insulin dependent diabetes), metabolic syndrome, glucose intolerance, and related health risks, symptoms or disorders. As such, the compounds can also be used to reduce body fat or body weight of an overweight or obese individual. In some embodiments, the PDE10 inhibitor is selective for PDE10, meaning that it is a better inhibitor of PDE10 than for any other PDE.
In some embodiments, the selective PDE10 inhibitor can reduce PDE10 activity at least 10-fold or at least 100-fold compared to other PDE's.

As used herein, the terms "overweight" and "obese" are meant to refer to adult persons 18 years or older having a greater than ideal body weight (or body fat) measured by the body mass index (BMI). BMI is calculated by weight in kilograms divided by height in meters squared (kg/m^2) or, alternatively, by weight in pounds, multiplied by 703, divided by height in inches squared (lbs x 703/in^2). Overweight individuals typically have a BMI of between 25 and 29, whereas obese individuals typically have a BMI of 30 or more (see, e.g., National Heart, Lung, and Blood institute, Clinical Guidelines on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults, The Evidence Report, Washington, DC: U.S. Department of Health and Human Services, NIH publication no. 98-4083, 1998). Other means for indicating excess body weight, excess body fat, and obesity include direct measure of body fat and/or waist-to-hip ratio measurements.

The term "metabolic syndrome" is used according to its usual meaning in the art. The American Heart Association characterizes metabolic syndrome as having at least 3 of the 5 below symptoms: 1) Elevated waist circumference (>102 cm (40 inches)) in men; (>88 cm (35 inches)) in women, 2) Elevated triglycerides (>150 mg/dL (>1.7 mmol/L) or drug treatment for elevated triglycerides), 3) Reduced HDL-C (<40 mg/dL (1.03 mmol/L) in men <50 mg/dL (1.3 mmol/L) in women or drug treatment for reduced HDL-C), 4) Elevated blood pressure (>130/85 mmHg or drug treatment for hypertension), and 5) Elevated fasting glucose (>100 mg/dL or drug treatment for elevated glucose). See, Grundy, S.M. et al., Circulation, 2005, 112(17), e285 (online at circ.ahajournals.org/cgi/reprint/112/17/e285). Metabolic syndrome according to the World Health Organization (See, Alberti et al., Diabet. Med. 15, 539-553, 1998) includes individuals suffering from diabetes, glucose intolerance, low fasting glucose, or insulin resistance plus two or more of 1) High blood pressure (>160/90 mmHg), 2) Hyperlipidemia (triglycerides >150 mg/dL or HDL cholesterol <35 mg/dL in men and <39 mg/dL in women), 3) Central obesity (waist-to-hip ratio of >0.90 for men and >0.85 for women or BMI >30 kg/m2), and 4) Microalbuminuria (urinary albumin excretion rate >20 µg/min or an albumin-to-creatinine ratio >20 µg/kg).

The present methods relating to reduction of body fat or body weight, as well as the treatment or prevention of obesity, type 2 diabetes (non-insulin dependent diabetes), metabolic syndrome, glucose intolerance, and related health risks, symptoms or disorders can be carried out by the administration of one or more compounds of the present invention. In some embodiments, one or more additional therapeutic agents can be administered such as anti-obesity agents. Example anti-obesity agents include apolipoprotein-B secretion/microsomal triglyceride transfer protein (apo-B/MTP) inhibitors, 11-beta-hydroxysteroid dehydrogenase-1 (11beta-HSD type 1) inhibitors, peptide YY3-36 or analogs thereof, MCR-4 agonists, cholecystokinin-A (CCK-A) agonists, monoamine reuptake inhibitors (such as sibutramine), cannabinoid receptor-I antagonists (such as rimona an, sympathomimetic agents, P3 adrenergic receptor agonists, 5 dopamine agonists; (such as
bromocriptine), melanocyte-stimulating hormone receptor analogs, SHT2c agonists, melanin
concentrating hormone antagonists, leptin (the OB protein), leptin analogs, leptin receptor agonists,

as the compounds described in U.S. Patent Nos. 6,566,367; 61649,624; 61638,942; 61605,720;
61495,569; 61462,053; 61388,077; 6,335,345; and 6,326,375; US Pat. Appl. Publ. Nos. 2002/0151456
and 20031036652; and PCT Publication Nos. WO 031010175, WO 03/082190 and
receptor agonists or antagonists, orexin receptor antagonists, glucagon-like peptide-1 receptor
agonists, ciliary neurotrophic factors, human agouti-related proteins (AGRP), ghrelin receptor
agonists, histamine 3 receptor antagonists or inverse agonists, neuromedin U receptor agonists and
the like. Other anti-obesity agents are readily apparent to one of ordinary skill in the art.

Scheme 4

6-Methoxy-2-(4-methyl-1H-imidazol-1-yl)-3-nitropyridine (IB)

To a N,N-dimethylformamide (500 mL) solution of 4-methylimidazole (8.5 g, 103 mmol) was added freshly powdered KOH (6.72 g, 120 mmol) in two portions under N₂ at 0°C, followed by addition of 2-chloro-6-methoxy-3-nitropyridine (18.9 g, 100 mmol). The resulting solution was warmed to room temperature and stirred for 2 hours. Majority of solvent was removed under vacuum and the residue was diluted with water and extracted with ethyl acetate three times. The organic layer was combined and washed two more times with water to remove additional dimethyl formamide and dried over magnesium sulfate. Solvent was evaporated under vacuum and the residue was purified by column (15-25% gradient eluent of ethyl acetate in dichloromethane) to provide compound IB as a yellow oil (21.9 g, 93% yield) which becomes yellow solid after standing on bench.

1H NMR (400MHz, DMSO) δ ppm 8.48 (d, 1H), 8.00 (s, 1H), 7.18 (s, 1H), 7.01 (d, 1H), 3.97 (s, 3H), 2.12 (s, 3H); EIMS 235.0 [M+H]+.

9-Bromo-6,7-dimethylimidazo[1,5-a]pyrido[3,2-e]pyrazin-2(1H)-one (8B)

To a mixture of substrate 5B (306 mg, 1 mmol) in 10 mL dichloroethane was added BBr$_3$ (0.8 mL, 8 mmol) dropwise at 0 °C. The resulting mixture was stirred at 80 °C overnight and then cooled to room temperature, poured into a solution of 2 g K$_2$CO$_3$ in 20 mL ice water. The crude product precipitated and was filtered, which was purified by column using 5% methanol in dichloromethane as eluent to provide 160 mg (55% yield) of product 8B as a yellow powder. [M+H]$^+$ 292.9 (ESI).

**Intermediate 1**: 2-Methyl-3-(4,4,5,5-tetramethyl-[1,3,2]dioxaborolan-2-yl)-pyridine

To this was added potassium acetate (2g, 20.3 mmol) followed by 4,4,5,5,4',4',5',5'-octamethyl-[2,2']bi[1,3,2]dioxaborolanyl] (1.9 g, 7.5 mmol) and [1,1-bis(diphenylphosphino)ferrocene]palladium(II) bis methylene chloride (0.47g, 10%mol).

5 Example A

Inhibition of PDE10

Method A

Phosphodiesterase isoenzyme 10 (PDE10) activity was determined in preparations of human recombinant PDE10A and PDE10 from pig striatum, respectively.

The DNA of PDE10A (AB 020593, 2340 bp) was synthesized and cloned into the vector pCR4.TOPO (Entelechon GmbH, Regensburg, Germany). The gene was then inserted into a baculovirus vector, ligated with the baculovirus DNA. The enzyme-protein was expressed in SF21-cells. The enzyme was isolated from these cells by harvesting the cells by a centrifugation at 200 g to collect the cells. The cells were resuspended in 50 mM Tris-HCl/5 mM MgCl2 buffer (pH=7.4) and lysed by a sonication of the cells. The cytosolic PDE10A was obtained by a centrifugation at 48000 g for 1 h in the supernatant and stored at -70°C.

Striatum from male hybrid pigs (150kg) were collected and frozen at -70°C. At the day of preparation 0.5 g striatum was homogenised in 10 ml 50 mM Tris/Mg-buffer at 4°C and centrifuged for one hour at 100000 g. The supernatant was removed and the pellet was resuspended in the same buffer, but containing 1% Triton and incubated for 45 min at 4°C. The membrane fraction was applied onto a 5 ml Hi TrapTM QHP column at the Äkta-FPLC. After washing the column the bound PDE protein was eluted with an increasing sodium chloride gradient (0 mM-500 mM sodium chloride) in 50 mM Tris/Mg-buffer at 4°C in the presence of 1% Triton. The eluted and collected fractions were tested with 100 nM [3H]-cAMP for PDE10-activity in the presence and without a specific PDE-Inhibitor at a concentration, were a 100% inhibition is expected. The fractions with PDE10-activity were pooled and frozen in aliquots until use at -20°C.

PDE10 activity was determined in a one step procedure in microtiterplates. The reaction mixture of 100 µl contained 50 mM Tris-HCl/5 mM MgCl2 buffer (pH=7.4) (Sigma, Deisenhofen, Germany; Merck, Darmstadt, Germany) 0.1 µM [3H]-cAMP (Amersham, Buckinghamshire, UK) and the enzyme. Nonspecific activity was tested without the enzyme. The reaction was initiated by addition of the substrate solution and was carried out at 37°C for 30 minutes. Enzymatic activity was
stopped by addition of 25 µl YSi-SPA-beads (Amersham-Pharmacia). One hour later the mixture was measured in a liquid scintillation counter for microtiterplates (Microbeta Trilux). To pipette the incubation mixture a robot Biomek (Fa. Beckman) is used. The determined Km-values for the substrate cAMP is 88 nM for pig striatum and 130 nM for human recombinant PDEIOA respectively. The optimal amount of enzyme in the assay has been determined and optimised for each enzyme preparation before using the enzyme in compound testing. For determination of IC50 values the Hill-plot, 2-parameter-model, was used. Specific inhibitors of other PDE-Subtypes do not inhibit the PDEIO preparation significantly. Papaverine was used as the most common PDEIO inhibitor and inhibits the PDEIO with IC50 values of 89 nM and 103 nM for PDEIO from human recombinant PDE IOA and PDE IO from striatum of pig respectively.

Method B

The phosphodiesterase isoenzyme 10 (PDEIO) activity was determined in preparations of rat, pig and guinea pig striatum respectively. Striatum from male Wistar rats (180-200 g), male hybrid pigs (150 kg) and male guinea pigs (CRL (HA), 500 g) respectively were collected and frozen at -70°C.

At the day of preparation 0.5 g striatum was homogenized in 10 ml 50 mM Tris/Mg-buffer at 4°C and centrifuged for one hour at 100000 g. The supernatant is called the cytosolic fraction and was removed and stored on ice. The pellet was resuspended in the same buffer, but containing 1% Triton and incubated for 45 min at 4°C. Both fractions were independently applied onto a 5ml Hi TrapTM QHP column at the Äkta-FPLC. After washing the columns the bound PDE protein was eluted with an increasing sodium chloride gradient (0 mM-500 mM sodium chloride) in 50 mM Tris/Mg-buffer at 4°C for the cytosolic fraction and in the presence of 1% Triton for the membrane fraction. The eluted and collected fractions were tested with 100 nM [3H]-cAMP for PDEIO-activity in the presence and without a specific PDE-Inhibitor at a concentration, were a 100% inhibition is expected. The fractions with PDE IO-activity were pooled and frozen in aliquots until use at -20°C.

The eluted fractions from the FPLC were additionally characterized by Western blot (Fig. 1). It was shown, that the PDEIOA containing pooled fractions include a great number of other proteins. Nevertheless PDEIO was detected with specific antibodies by Western blot clearly.

The protein was proven in the preparation of the striatum of the rat, the pig and the guinea pig. The main part of protein was found in the membrane fraction (Fig. 2).

In the prepared brain areas gene segments containing the catalytic domain of the PDE IO were amplified and the sequence determined.

Therefore the RNA from the frozen striatum of the different animals was isolated according to the instructions of the RNeasy kit (Qiagen; Hilden; Germany) and transcribed into cDNA using Oligo-Primer provided with the 1st strand cDNA synthese kit for RT-PCR (Roche; Mannheim; Germany). These cDNA was used as template for the PCR-reaction to amplify the catalytic domain of
the PDElO. For the PCR reaction Taq-Polymerase (Promega; Mannheim; Germany) was used. Therefore it was possible to clone the amplificates directly by TA-cloning in the pCR2.1 vector (Invitrogen; Karlsruhe; Germany). The cloning vector was transformed into E.coli's (XL-2), replicated within the cells, prepared and the included gene sequence determined for the pig and the guinea pig.

The following primers were used for the PCR-reaction:

Compound Data

The compounds of formula (I) are potent inhibitors of PDE10. A substance is considered to effectively inhibit PDE10 if it has an IC_{50} of less than 10 µM, e.g., less than 1 µM. IC_{50} values for select compounds are provided in Tables 7, 8, and 9, where "+" indicates that the IC_{50} value is less than or equal to 10 nM; "++" indicates that the IC_{50} value is between 10 -100 nM; and "+++" indicates that the IC_{50} value is equal to or greater than 100 nM.
