(54) Title: PROBE ASSEMBLY FOR CREATING CIRCUMFERENTIAL LESIONS WITHIN OR AROUND A VESSEL OS-
TIUM

(57) Abstract: A probe assembly for ablating tissue around a vessel ostium, including an outer probe including an elongate probe body having a distal ablative structure, a lumen having an exit port, and one or more ablative elements mounted to the distal ablative structure; and an inner probe configured to be slidably disposed within the lumen of the outer probe, the inner probe including an elongate probe body having a distal diagnostic structure configured to extend out the exit port, and one or more diagnostic elements mounted to the distal diagnostic structure.

WO 2005/030072 A1

PROBE ASSEMBLY FOR CREATING CIRCUMFERENTIAL LESIONS WITHIN OR
AROUND A VESSEL OSTIUM

FIELD OF THE INVENTION

5 This invention relates to medical ablation systems, and more particularly to systems for ablating tissue in and around vessels ostiums.

BACKGROUND OF THE INVENTION

Surgical methods of treating atrial fibrillation by interrupting pathways for reentry circuits include the so-called "maze procedure," which relies on a prescribed
10 pattern of incisions to anatomically create a convoluted path, or maze, for electrical propagation within the left and right atria. Maze-like procedures have also been developed utilizing catheters, which can form lesions on the endocardium (the lesions being 1 to 15 cm in length and of varying shape) to effectively create a maze for electrical conduction in a predetermined path. The formation of these lesions by
15 soft tissue coagulation (also referred to as "ablation") can provide the same therapeutic benefits that the complex incision patterns that the surgical maze procedure provides, but without invasive, open heart surgery.

One lesion that has proven to be difficult to form with conventional devices is the circumferential lesion that is used to isolate the pulmonary vein and cure ectopic
20 atrial fibrillation. Lesions that isolate the pulmonary vein may be formed within the pulmonary vein itself or in the tissue surrounding the pulmonary vein. Ablation of pulmonary veins is currently performed by placing a diagnostic catheter (such as Biosense Webster's Lasso™ circular ECG catheter, Irvine Biomedical's Afocus™ circular ECG catheter, or Boston Scientific Corporation's Constellation™ ECG
25 catheter) into the pulmonary vein to be treated, and then ablating the pulmonary

tissue adjacent to the distal end of the selected diagnostic catheter with a standard, commercially available ablation catheter. The diagnostic catheter is used to determine if the lesion created by the ablation catheter has been successful in electrically isolating the pulmonary vein.

5 Some physicians may alternatively use a standard linear diagnostic catheter with 2-20 ECG electrodes to evaluate pre-ablation electrocardiogram (ECG) recordings, then swap the diagnostic catheter with a standard ablation catheter either through the same sheath, or in conjunction with the ablation catheter through a second sheath, ablating the pulmonary tissue, and then swapping the ablation
10 catheter with the diagnostic catheter to evaluate post-ablation ECG recordings.

 In any event, the circumferential lesion must be iteratively formed by placing the ablation electrode into contact with a tissue region, ablating the tissue region, moving the ablation electrode into contact with another tissue region, and then ablating again. In a standard procedure, placement of the electrode and ablation of
15 tissue may be repeated from 15-25 times to create the circumferential lesion. It is often difficult to form an effective circumferential lesion, however, by forming a pattern of relatively small diameter lesions. More recently, inflatable balloon-like devices that can be expanded within or adjacent to the pulmonary vein have been introduced. Although the balloon-like devices are generally useful for creating
20 circumferential lesions, these devices have the undesirable effect of occluding blood flow through the pulmonary vein.

 In response to these problems, a corkscrew-type ablation catheter has been recently designed. This catheter comprises a helical distal end on which a plurality of ablation electrodes are mounted. The helical distal end can be inserted into a
25 pulmonary vein to be treated and operated to efficiently produce a circumferential

lesion, while allowing passage of blood. The ablation electrodes on the corkscrew-type ablation catheter can also be used to generate ECG recordings as a frame of reference for the ablation procedure. In use, it has been noted that ECG drops in amplitude are an indicator of potential pulmonary vein electrical isolation. Although
5 this technique has proven successful, the ablation device does not offer as high of an ECG signal resolution as would a dedicated ECG catheter.

SUMMARY OF THE INVENTION

In accordance with a first embodiment of the invention, a probe for ablating
10 tissue, e.g., the tissue within a pulmonary vein, is provided. The probe comprises an outer elongate probe body (e.g., an intravascular catheter body or a surgical probe body) including a distal ablative structure having an open architecture defining an interior space. For example, the distal ablative structure can be a loop structure or an open helical structure. The probe further comprises a lumen extending through
15 the outer probe body. The lumen is configured to slidably receive an inner elongate probe body, and comprises an exit port out which the inner probe body can extend within the interior space of the ablative structure. The probe further comprises one or more ablative elements mounted to the distal ablative structure, wherein the one or more ablative elements are arranged to create a circumferential lesion. For
20 example, the ablative structure of the outer probe body can be configured to be disposed within or around the ostium of a pulmonary vein, in which case, the ablative element(s) can be configured to circumferential contact tissue within or around the ostium of the pulmonary vein.

In accordance with another embodiment of the invention, a probe assembly
25 for ablating tissue is provided. The probe assembly comprises an outer probe body

that includes an ablative structure, e.g., a loop structure, open helical structure, or expandable balloon. The probe assembly further comprises an inner probe configured to be slidably disposed within the lumen of the outer probe. The inner probe includes an elongate probe body having a distal diagnostic structure

5 configured to extend out the exit port, and one or more diagnostic elements (e.g., electrophysiology mapping elements) mounted to the distal diagnostic structure. The diagnostic structure may be formed of a single spline to provide a low profile, or some other structure, such as a basket structure. The diagnostic structure may be configured to assume an curvilinear shape in order to provide a firm and stable

10 contact between the diagnostic elements and the tissue.

BRIEF DESCRIPTION OF THE DRAWINGS

The drawings illustrate the design and utility of embodiments of the invention, in which similar elements are referred to by common reference numerals, and in

15 which:

Fig. 1 is a plan view of one embodiment of a medical treatment system, constructed in accordance with the invention;

Fig. 2 is a plan view of an ablation/mapping catheter assembly that can be used in the medical treatment system of **Fig. 1**;

20 **Fig. 3** is a cross-sectional view of the catheter assembly of **Fig. 2**, taken along the lines 3-3;

Fig. 4 is a plan view of another ablation/mapping catheter assembly that can be used in the medical treatment system of **Fig. 1**;

Fig. 5 is a profile view of the catheter assembly of **Fig. 4**;

Fig. 6 is a plan view of still another ablation/mapping catheter assembly that can be used in the medical treatment system of **Fig. 1**, wherein a balloon electrode structure is particularly shown in a collapsed geometry;

Fig. 7 is a plan view of the catheter assembly of **Fig. 6**, wherein the balloon electrode structure is particularly shown in an expanded geometry; and

Fig. 8 is a plan view showing yet another ablation/mapping catheter assembly to create a circumferential lesion within the ostium of a vessel.

DETAILED DESCRIPTION OF THE ILLUSTRATED EMBODIMENTS

The embodiments disclosed herein may be used within body lumens, chambers or cavities for diagnostic or therapeutic purposes in those instances where access to interior bodily regions is obtained through, for example, the vascular system or alimentary canal and without complex invasive surgical procedures. For example, the embodiments herein have application in the diagnosis and treatment of arrhythmia conditions within the heart. The embodiments herein also have application in the diagnosis or treatment of ailments of the gastrointestinal tract, prostate, brain, gall bladder, uterus, and other regions of the body.

With regard to the treatment of conditions within the heart, the embodiments herein are designed to produce intimate tissue contact with target substrates associated with various arrhythmias, namely atrial fibrillation, atrial flutter, and ventricular tachycardia. For example, the distal portion of a catheter used in the embodiments herein can be used to create lesions within or around the pulmonary vein to treat ectopic atrial fibrillation.

Although the embodiments illustrated herein are catheter-based, the embodiments are adaptable for use with probes other than catheter-based probes. For example, the structures disclosed herein may be used in conjunction with hand

held surgical devices (or "surgical probes"). The distal end of a surgical probe may be placed directly in contact with the targeted tissue area by a physician during a surgical procedure, such as open heart surgery. Here, access may be obtained by way of a thoracotomy, median sternotomy, or thoracostomy. Exemplary surgical probes are disclosed in U.S. Pat. No. 6,142,994.

Referring to **Fig. 1**, an exemplary ablation/diagnostic system 10 constructed in accordance with the invention is shown. The system 10 may be used within body lumens, chambers or cavities for diagnostic or therapeutic purposes in those instances where access to interior bodily regions is obtained through, for example, the vascular system or alimentary canal and without complex invasive surgical procedures. For example, the system 10 has application in the diagnosis and treatment of arrhythmia conditions within the heart. The system 10 also has application in the diagnosis or treatment of ailments of the gastrointestinal tract, prostate, brain, gall bladder, uterus, and other regions of the body. As an example, the system 10 will be described hereinafter for use in pulmonary veins, and specifically, to electrically isolate a pulmonary vein from the left atrium of the heart in order to treat ectopic atrial fibrillation.

The system 10 generally comprises an ablation/diagnostic catheter assembly 12, which includes a guide sheath 14, an ablation catheter 16 that can be guided through the guide sheath 14, and a diagnostic catheter, and specifically, a mapping catheter 18, integrated within the ablation catheter 16. As will be described in further detail below, the catheter assembly 12 is configured to be introduced through the vasculature of the patient, and into the left atrium of the heart, where it can be used to map and ablate the tissue within and around a selected pulmonary vein. The

treatment system 10 further comprises an ablation source, and specifically, a radio frequency (RF) generator 20, and an mapping processor 22.

The mapping processor 22 is configured to record and process ECG signals obtained from the mapping catheter 18 to determine irregular electrical signals within the heart, and specifically electrical signals adjacent the ostia of the pulmonary veins. Recording ECG signals is well known in the art, and thus for purposes of brevity, the mapping processor 22 will not be described in further detail. The RF generator 20 is configured to deliver ablation energy to the ablation catheter 16 in a controlled manner in order to ablate the area around the ostium of the pulmonary vein identified by the mapping processor 22. Alternatively, other types of ablative sources besides the RF generator 20 can be used, e.g., a microwave generator, an ultrasound generator, a cryoablation generator, and a laser or other optical generator. Ablation of tissue within the heart is well known in the art, and thus for purposes of brevity, the RF generator 20 will not be described in further detail. Further details regarding RF generators are provided in U.S. Patent No. 5,383,874.

The ablation catheter 16 is not a steerable catheter and, accordingly, may be advanced through the conventional steerable guide sheath 14 to the target location. The sheath 14, which should be lubricious to reduce friction during movement of the ablation catheter 16, may be advanced over a guidewire in conventional fashion. Alternatively, a steerable sheath may be provided. With respect to materials, the proximal portion of the sheath 14 is preferably a Pebax® material and stainless steel braid composite, and the distal portion is a more flexible material, such as unbraided Pebax®, for steering purposes. The sheath 14 should also be stiffer than the ablation catheter 16. A sheath introducer (not shown), such as those used in combination with basket catheters, may be used when introducing the ablation

catheter 16 into the sheath 14. The guide sheath 14 preferably includes a radio-opaque compound, such as barium, so that the guide sheath 14 can be observed using fluoroscopic or ultrasound imaging, or the like. Alternatively, a radio-opaque marker (not shown) can be placed at the distal end of the guide sheath 14.

5 Referring now to **Fig. 2**, the ablation catheter 16 comprises a flexible catheter body 24 formed of a proximal member 28 and a distal member 26. The proximal member 26 is relatively long (e.g., 80-100 cm), while the distal member 26 is relatively short (e.g., 2-10 cm). The proximal member 26 is preferably formed from a biocompatible thermoplastic material, such as a Pebax® material (polyether block
10 amide) and stainless steel braid composite, which has good torque transmission properties. In some implementations, an elongate guide coil (not shown) may also be provided within the proximal member 26. A handle assembly 31 (shown in **Fig. 1**) is mounted to the proximal end of the proximal member 26. The distal member 26 is preferably formed from a softer, more flexible biocompatible thermoplastic material
15 such as unbraided Pebax® material, polyethylene, or polyurethane. The proximal and distal members, which are about 5 French to about 9 French in diameter, are preferably either bonded together at interface 30 with an overlapping thermal bond or adhesively bonded together end to end over a sleeve in what is referred to as a "butt bond."

20 The distal member 26 of the ablation catheter body 24 forms an unconstrained open helically-shaped ablative structure 32 on which ablation electrodes 34 are mounted. The ablative structure 32 defines a longitudinal axis coincident with the longitudinal axis of the remainder of the catheter body 24. The number of revolutions (or "coils"), length, diameter, orientation and shape of the
25 helical structure will vary from application to application. In the illustrated

embodiment, the ablative structure 32 revolves around the longitudinal axis of the catheter body 24 two and one-half times in its relaxed state, and can be defined with a proximal coil 36, medial coil 38, and distal coil 40.

Although the diameter of the ablative structure 32 can alternatively be
5 substantially constant over its length, as illustrated in **Fig. 2**, the ablative structure 32 preferably has a generally frusto-conical shape, where the diameter decreases in the distal direction. Specifically, when used in pulmonary veins, the proximal coil 36 of the ablative structure 32 preferably has an outer diameter that will cause it abut the pulmonary vein ostium (e.g., between about 15 mm and about 35 mm), and the
10 distal coil 40 of the ablative structure 32 preferably has an outer diameter suitable for placement within the pulmonary vein (e.g., between about 5 mm and about 10 mm). The ablative structure 32 will, therefore, be self-centering when inserted into the pulmonary vein, because the tapered ablative structure 32 will wedge itself against the pulmonary vein ostium and the internal wall of pulmonary vein itself. Not only
15 does this result in proper positioning of the electrodes 34, the wedging effect also prevents beating related movement of the heart from the knocking the ablation catheter 16 out of position once it is in place.

The distal member 26 of the catheter body 24 also forms a distal anchoring structure 42, which allows the ablative structure 32 to be precisely located relative to
20 the pulmonary vein. More specifically, advancing the anchoring structure 42 into the pulmonary vein aligns the ablative structure 32 with the pulmonary vein. In the illustrated embodiment, the anchoring structure 42 is simply the portion of the distal member 26 that is distal to the ablative structure 32. Alternatively, a separate structure may be secured to the distal end of the distal member 26. The exemplary

anchoring structure 42 is approximately 1 to 2 inches in length, although other lengths may be used to suit particular applications.

Referring to **Fig. 3**, the shape of the ablative structure 32 is achieved through the use of a center support 44 that is positioned inside of and passes within the length of the distal member 26. In the illustrated embodiment, the center support 44 is a rectangular wire formed from resilient inert wire, such as Nickel Titanium (commercially available under the trade name Nitinol) or 17-7 stainless steel wire, with a portion thereof heat set into the desired helical configuration. Alternatively, the center support 44 can be circular. The thickness of the rectangular center support 44 is preferably between about 0.010 inch and about 0.015 inch. Resilient injection molded plastic can also be used. Although other cross sectional configurations can be used, such as a round wire, a rectangular cross section arranged such that the longer edge extends in the longitudinal direction is preferred for at least the ablative structure 32.

Such an orientation reduces the amount of torsional force, as compared to a round wire, required to unwind the ablative structure 32 into an expanded configuration and collapse the ablative structure 32 into a linear structure. The center support 44 is preferably housed in an insulative tube 46 formed from material such as Teflon® or polyester. Additional details concerning the placement of a center support within the distal member of a catheter can be found in commonly assigned U.S. Patent No. 6,287,301.

Preferably, the distal portion of the distal member 26 is more flexible than the proximal portion of the distal member 26 in order to prevent tissue damage when attempts are made to insert the ablative structure 32 into a pulmonary vein. In addition, the ablative structure 32 will be more predisposed to easily uncoil for

placement within the sheath 14, remain uncoiled and slide through the sheath 14 until it exits through the distal end of the sheath and re-coils, and then easily uncoil again when pulled back into the sheath after the procedure is completed. Also, the stiffer proximal portion of the distal member 26 allows the physician to press the ablation electrodes 34 against the tissue with more force when lesions are being created.

The flexibility of the distal portion of the distal member 26 can be increased in variety of ways, e.g., by using a core wire (not shown) having a varying stiffness, or by constructing the distal member 26 from different materials. Further details on the construction of helical structures with varying flexibility are disclosed in U.S. Patent No. 6,745,080.

The ablation catheter 16 may comprise an optional stylet (not shown) that enables the physician to manipulate the ablative structure 32 and adjust its shape by longitudinally and/or rotating the stylet. Further details on the construction and use of the stylette, along with a handle assembly specifically designed to manipulate the stylette, are disclosed in U.S. Patent Application Ser. No. 09/832,612.

The ablation catheter 16 comprises a lumen 48 (in addition to other lumens for providing ablation and signals wires described below) for slidably receiving the mapping catheter 18 (shown in **Fig. 2**). The lumen 48 proximally terminates in the handle assembly 31 at an insertion port 50 (shown in **Fig. 1**) and distally terminates in the distal member 26 at an exit port 52 (shown in **Fig. 2**) just proximal to the ablative structure 32. Thus, the mapping catheter 18 can be introduced into the insertion port 50 on the handle assembly 31, through the lumen 48, and out the exit port 52, so that it extends within an interior space 54 created by the ablative structure 32.

The spaced ablation electrodes 34 are preferably in the form of wound, spiral coils. The coils are made of electrically conducting material, like copper alloy, platinum, or stainless steel, or compositions such as drawn-filled tubing (e.g. a copper core with a platinum jacket). The electrically conducting material of the coils can be further coated with platinum-iridium or gold to improve its conduction properties and biocompatibility. A coil electrode is disclosed in U.S. Patent No. 5,797,905. The electrodes 34 are electrically coupled to individual wires 55 (shown in **Fig. 3**) to conduct coagulating energy to them. The wires are passed in conventional fashion through a lumen extending through the associated catheter body into a PC board (not shown) in the handle assembly 31, where they are electrically coupled to a connector (not shown) that is received in a port on the handle assembly 31. The connector plugs into the RF generator 20 (shown in **Fig. 1**).

As an alternative, the ablation electrodes 34 may be in the form of solid rings of conductive material, like platinum, or can comprise a conductive material, like platinum-iridium or gold, coated upon the device using conventional coating techniques or an ion beam assisted deposition (IBAD) process. For better adherence, an undercoating of nickel or titanium can be applied. The electrodes 34 can also be in the form of helical ribbons. The electrodes 34 can also be formed with a conductive ink compound that is pad printed onto a nonconductive tubular body. One such conductive ink compound is a silver-based flexible adhesive conductive ink (polyurethane binder), however other metal-based adhesive conductive inks such as platinum-based, gold-based, copper-based, etc., may also be used to form electrodes 34. Such inks are more flexible than epoxy-based inks.

The flexible electrodes 34 are preferably about 4 mm to about 20 mm in length. In one embodiment, the electrodes are 12.5 mm in length with 1 mm to 3 mm

spacing, which will result in the creation of continuous lesion patterns in tissue when coagulation energy is applied simultaneously to adjacent electrodes 34. For rigid electrodes 34, the length of the each electrode can vary from about 2 mm to about 10 mm. Using multiple rigid electrodes 34 longer than about 10 mm each adversely
5 effects the overall flexibility of the device, while electrodes 34 having lengths of less than about 2 mm do not consistently form the desired continuous lesion patterns.

The portion of the electrodes 34 that are not intended to contact tissue (and be exposed to the blood pool) may be masked through a variety of techniques with a material that is preferably electrically and thermally insulating. This prevents the
10 transmission of coagulation energy directly into the blood pool and directs the energy directly toward and into the tissue. For example, a layer of UV adhesive (or another adhesive) may be painted on preselected portions of the electrodes 34 to insulate the portions of the electrodes not intended to contact tissue. Deposition techniques may also be implemented to position a conductive surface only on those portions of
15 the assembly intended to contact tissue. Alternatively, a coating may be formed by dipping the electrodes 34 in PTFE material.

The electrodes 34 can include a porous material coating, which transmits coagulation energy through an electrified ionic medium. For example, as disclosed in U.S. Pat. No. 5,991,650, electrodes 34 may be coated with regenerated cellulose,
20 hydrogel or plastic having electrically conductive components. With respect to regenerated cellulose, the coating acts as a mechanical barrier between the surgical device components, such as electrodes, preventing ingress of blood cells, infectious agents, such as viruses and bacteria, and large biological molecules such as proteins, while providing electrical contact to the human body. The regenerated
25 cellulose coating also acts as a biocompatible barrier between the device

components and the human body, whereby the components can now be made from materials that are somewhat toxic (such as silver or copper).

The electrodes 34 may be operated in a uni-polar mode, in which the soft tissue coagulation energy emitted by the electrodes 34 is returned through an
5 indifferent patch electrode (not shown) externally attached to the skin of the patient. Alternatively, the electrodes 34 may be operated in a bi-polar mode, in which energy emitted by one or more electrodes 34 is returned through other electrodes 34. The amount of power required to coagulate tissue ranges from 5 to 150 W.

Although ablation electrodes 34 have been described as the operative
10 elements that create the lesion, other operative elements, such as lumens for chemical ablation, laser arrays, ultrasonic transducers, microwave electrodes, and ohmically heated hot wires, and such devices may be substituted for the electrodes 34.

The ablation catheter 16 further comprises temperature sensors (not shown),
15 such as thermocouples or thermistors, which may be located on, under, abutting the longitudinal end edges of, or in between, the electrodes 34. Preferably, the temperature sensors are located at the longitudinal edges of the electrodes 34 on the distally facing side of the ablative structure 32. In some embodiments, a reference thermocouple (not shown) may also be provided. For temperature control
20 purposes, signals from the temperature sensors are transmitted to the source of coagulation energy by way of wires 60 (shown in **Fig. 3**) that are also connected to the aforementioned PC board in the handle assembly 31. Suitable temperature sensors and controllers which control power to electrodes based on a sensed temperature are disclosed in U.S. Pat. Nos. 5,456,682, 5,582,609 and 5,755,715.

The mapping catheter 18 comprises a flexible catheter body 62 formed of a flexible spline composed of a resilient, biologically inert material, like Nitinol metal or silicone rubber. Thus, the mapping catheter body 62 is configured to bend and conform to the endocardial and pulmonary vein tissue surface its contacts. In the
5 illustrated embodiment, the diameter of the mapping catheter body 62 is relatively small (e.g., 3-4F), so that the ablation catheter 16 that houses the mapping catheter 18 assumes a small profile.

The distal end of the mapping catheter body 62 forms a mapping structure 64. The mapping catheter 18 comprises mapping electrodes 58 extending along the
10 mapping structure 64. In the illustrated embodiment, the mapping electrodes 58 are ring electrodes that are composed of a solid, electrically conducting material, like platinum or gold, attached about the catheter body 62. Alternatively, the mapping electrodes 58 can be formed by coating the exterior surface of the catheter body 62 with an electrically conducting material, like platinum or gold. The coating can be
15 applied using sputtering, ion beam deposition, or equivalent techniques. The mapping electrodes 58 can have suitable lengths, such as between 0.5 and 5 mm.

In use, the mapping electrodes 58 sense electrical events in myocardial tissue for the creation of electrograms, and are electrically coupled to the mapping processor 22 (see **Fig. 1**). A signal wire (not shown) is electrically coupled to each
20 mapping electrode 58. The wires extend through the catheter body 62 into an external multiple pin connector 66. The connector 66 electrically couples the mapping electrodes 58 to the mapping processor 22.

As illustrated in **Fig. 2**, the mapping structure 64 extends distally within an interior space 54 of the ablative structure 32, and is curved in an undulated fashion
25 that will resiliently place the mapping electrodes 58 in contact with the tissue of the

vessel in which the ablation and mapping catheters 16 and 18 are placed.

Specifically, the total transverse distance that the mapping structure 64 curves is greater than the diameter of the selected vessel, so that placement of the mapping structure 64 within the vessel will cause the vessel wall to provide a compressive
5 force mapping structure 64, thereby resiliently lodging the mapping structure 64 within the vessel.

In the illustrated embodiment, the mapping structure 64 comprises first and second curved sections 68 and 70 having apices that point in the same direction away from the longitudinal axis of the ablation catheter 16, and an mediate curved
10 section 72 between the proximal and distal curved sections 68 and 70 having an apex that points towards the longitudinal axis of the ablation catheter 16. In this manner, when the mapping structure 64 is deployed from the exit port 52 of the ablation catheter lumen 48, the proximal curved section 68 may come in contact with tissue between the proximal and medial coils 36 and 38 of the ablative structure 32,
15 and the distal curved section 70 may come in contact with tissue between the mediate and distal coils 38 and 40 of the ablative structure 32. The medial curved section 72 provides clearance between the mapping structure 64 and the medial coil 38 of the ablative structure 32.

The distal end of the mapping catheter body 62 further forms a straight distal
20 section 74 that is configured to stabilize the mapping structure 64 by contacting the portion of the vessel wall opposite the portion in which the proximal and distal curved sections 68 and 70 contact. Preferably, the distal section 74 is floppy, similar to the tip of a guidewire, thereby minimizing tissue trauma.

It should be noted that although the mapping catheter body 62 has been
25 described as a linear resilient spline, the catheter body 62 can also have other

shapes, such as, e.g., a spiral, basket, etc., that allow the mapping catheter body 62 to collapse into the lumen 48 of the ablation catheter body 62.

Referring now to **Fig. 4**, an alternative embodiment of a catheter assembly 112 that can be used in the treatment system 10 of **Fig. 1** is shown. The catheter assembly 112 is similar to the previously described catheter assembly 12, with the exception that the ablation catheter body forms a loop-shaped, rather than a helically-shaped, ablative structure. Specifically, an ablation catheter 116 comprises a flexible elongate catheter body 124 having a distal member 126 that forms a loop-shaped ablative structure 132. The ablation catheter 116 further comprises a pull wire 134, which extends from the tip of the distal member 126 back through the sheath 32. The pull wire 134 is used to pull the distal member 116 into a loop configuration. The pull wire 134 also maintains the shape of the ablative structure 132 (thereby insuring good tissue contact) when the loop structure 132 is urged against tissue, such as a pulmonary vein ostium.

In the illustrated embodiment, the ablative structure 132 forms a curved portion with a radius of about 0.5 inch. The curved portion lies in a plane between about 30 and about 60 degrees, and preferably about 45 degrees, out of the horizontal catheter plane, as illustrated in **Fig. 5**. The preset curvature may be accomplished in a variety of ways. Preferably, the curved portion is preset through the use of a thermal forming technique (100° C for 1 hour). The preset curvature may also be accomplished through the use of a pre-shaped core wire (not shown) formed from Nitinol or 17-7 stainless steel. The curved portion will typically be bent out of its pre-bent orientation when the ablative structure 132 is urged against tissue (note the dashed lines in **Fig. 5**). As a result, a spring force that urges the ablative

structure 132 against the tissue is generated, thereby improving tissue/electrode contact.

The pull wire 134 is preferably a flexible, inert cable constructed from strands of metal wire material, such as Nitinol or 17-7 stainless steel, that is about 0.012 inch to about 0.025 inch in diameter. Alternatively, the pull wire 134 may be formed from a flexible, inert stranded or molded plastic material. The pull wire 134 is also preferably round in cross-section, although other cross-sectional configurations can be used. Further details on the construction of loop-shaped ablative structures and pull wires are disclosed in U.S. Patents Nos. 6,745,080 and 6,048,329.

The catheter assembly 112 further comprises a mapping catheter 118 that includes a catheter body 164 with a mapping structure 164 that extends distally through an interior space 156 of the ablative structure 132. The mapping structure 164 is similar to the previously described mapping structure 64, with the exception that it forms a single curve that will extend along one side of the pulmonary vein contralaterally to a straight distal section 174.

Referring now to **Figs. 6 and 7**, another alternative embodiment of a catheter assembly 212 that can be used in the treatment system 10 of **Fig. 1** is shown. The catheter assembly 212 is similar to the previously described catheter assembly 12, with the exception that an expandable-collapsible ablative structure, rather than a helically-shaped ablative structure, is formed at the distal end of the ablation catheter body.

Specifically, an ablation catheter 216 comprises a flexible elongate catheter body 224 having a distal member 226 on which there is mounted an expandable-collapsible ablative structure 232. The ablative structure 232 is formed by a "balloon-like" wall suitably bonded to and disposed about the distal member 226.

The geometry of the ablative structure 232 can be altered between a collapsed, low profile geometry (**Fig. 6**), and an expanded, high profile geometry (**Fig. 13**). The ablation catheter body 224 comprises inflation and venting lumens (not shown) that extend from a handle assembly (not shown) to the interior region of the ablative structure 232. The catheter body 224 comprises a lumen (not shown) that terminates in an exit port 252 out which the previously described mapping structure 164 of the mapping catheter 118 extends. The exit port 252, in this case, is distal to the ablative structure 232.

In order to inflate the ablative structure 232, a liquid inflation medium, such as water, saline solution, or other bio-compatible fluid, is conveyed under positive pressure through a port on the handle assembly, through the inflation lumen extending through the catheter body 224. The liquid medium fills the interior of the ablative structure 232 and exerts pressure on the inside of the ablative structure 232 to urge the ablative structure from its collapsed geometry (**Fig. 6**) to its expanded geometry (**Fig. 7**). Constant exertion of pressure through the inflation lumen maintains the ablative structure 232 in its expanded geometry. The venting lumen is used to vent any air or excess fluid from the ablative structure 232. Alternatively, the inflating fluid medium can comprise a gaseous medium, such as carbon dioxide.

Preferably, the ablative structure 232 is less than 8 French diameter when in a collapsed geometry for ease of manipulation through the vasculature, and about 2.0 cm in circumference around its largest portion when in its expanded geometry and located in a desired ablation region within the pulmonary vein. The ablative structure 232 is preferably made of a suitable biocompatible, thermoplastic or elastomeric material, and can be configured to have any one of many shapes in its expanded

geometry, such as the shape shown in **Fig. 7**, depending on the desired resulting geometry.

Proximate the center of the ablative structure 232 is a pronounced circumferential region 236 having a larger circumference than that of the rest of the ablative structure 232. In this manner, expansion of the ablative structure 232 within the pulmonary vein provides a force that is concentrated between the enlarged circumferential region 236 and the interior surface of a pulmonary vein in which the ablative structure 232 is situated, thus enhancing the lesion creating characteristics of the ablative structure 232.

The ablation catheter 216 comprises an electrode that takes the form of a conductive shell 234 made of a material having a relatively high electrical and thermal conductivity that is suitably deposited on the outer surface of the ablative structure 232 over the enlarged circumferential region 236 using ion deposition or equivalent techniques. Materials possessing these characteristics include, among others, gold, platinum, platinum/iridium, conductive ink epoxy, or a combination thereof. In particular, noble metals are preferred.

The area of the ablative structure 232 located immediately proximal and distal to the enlarged circumferential region 236 is preferably masked prior to the deposition of the conductive material, so that resulting non-conductive regions 238 and 240 are formed on either side of the conductive shell 234. In particular, the masking of the regions on either side on the conductive region assures that the maximum current density will be distributed at the enlarged circumferential region 236 of the ablative structure 232, thereby allowing the ablative structure 232 to efficiently form annular lesions within the pulmonary vein. In order to deliver current,

the conductive shell 234 is coupled to a plurality of insulated ablation wires (not shown), that are in turn coupled to the handle assembly (not shown).

There are many modifications that can be made to the ablative structure 232. For example, the conductive shell 234 may be segmented instead of continuous.

- 5 The ablative structure 232 may be microporous, allowing ions to pass from an interior electrode, through the pores, into the tissue. The ablative structure 232 may have an interior support structure (such as resilient splines or mesh or a foam substance) arranged to apply an outward force against the electrode structure 232 to augment, or replace, the outward force caused by a pressurized liquid medium. The
- 10 ablative structure 232 may comprise blood lumens for allowing the flow of blood through the ablative structure 232 when expanded within the pulmonary vein. The ablative structure 232 may be shaped, such that a portion of the conductive shell 234 engages the ostium of the pulmonary vein.

- Other types of ablative structures, besides balloon-like ablative structures, can
- 15 be envisioned. For example, a basket-type ablative structure having a plurality of resilient splines with ablation electrodes mounted thereon can be used to create a circumferential lesion within the pulmonary vein. Pre-shaped ablative loop structures that are either coplanar with, or orthogonal to, the longitudinal axis of the catheter body can also be used to create lesions within or around the pulmonary vein. In
- 20 each case, a lumen for housing the mapping catheter 118, and an exit port out which the mapping electrode structure 164 extends, can be incorporated into the design.

- In all of the previously described embodiments, the mapping catheters are configured to be introduced through lumens contained within the ablation catheters. Alternatively, as illustrated in **Fig. 8**, the ablation catheter 16 and mapping catheter
- 25 18 can be independently introduced through the lumen of the guide sheath 14.

CLAIMS

1. A probe assembly for ablating tissue around a vessel ostium, comprising:
an outer probe including an elongate probe body having a distal ablative
5 structure, a lumen having an exit port, and one or more ablative elements mounted
to the distal ablative structure; and
an inner probe configured to be slidably disposed within the lumen of the
outer probe, the inner probe including an elongate probe body having a distal
diagnostic structure configured to extend out the exit port, and one or more
10 diagnostic elements mounted to the distal diagnostic structure.
2. The probe assembly of claim 1, wherein the outer probe body is an
intravascular catheter body.
3. The probe assembly of claims 1 or 2, wherein the distal ablative structure is a
loop structure.
- 15 4. The probe assembly of claims 1 or 2, wherein the distal ablative structure is
an open helical structure.
5. The probe assembly of claim 4, wherein the open helical structure is tapered.
6. The probe assembly of claims 1 or 2, wherein the distal ablative structure is
an expandable balloon.
- 20 7. The probe assembly of claims 1 or 2, wherein the distal ablative structure is
an open structure that forms an interior space, and the distal diagnostic structure is
configured to extend within the interior space.
8. The probe assembly of claims 1 or 2, wherein the distal ablative structure is
configured to be disposed within or around the ostium of a pulmonary vein, and the

one or more ablative elements are configured to circumferentially contact tissue within or around the ostium of the pulmonary vein.

9. The probe assembly of any of claims 1 - 8, wherein the distal diagnostic structure comprises a single spline.
- 5 10. The probe assembly of any of claims 1 - 8, wherein the distal diagnostic structure is configured to assume a curvilinear shape.
11. The probe assembly of any of claims 1 - 10, wherein the one or more diagnostic elements comprises one or more electrophysiology mapping elements.
12. The probe assembly of any of claims 1 - 11, further comprising a guide sheath
10 for housing the outer probe.
13. The probe assembly of any of claims 1 - 12, wherein the exit port is proximal to the distal ablative structure.
