COMBINATION THERAPY WITH C-MET AND EGFR ANTAGONISTS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority under 35 USC § 119(e) to U.S. provisional application number 61/034,446, filed March 6, 2008, and U.S. provisional application number 61/044,438, filed April 11, 2008, the contents of which are incorporated herein by reference.

TECHNICAL FIELD

The present invention relates generally to the fields of molecular biology and growth factor regulation. More specifically, the invention relates to combination therapies for the treatment of pathological conditions, such as cancer.

BACKGROUND

HGF is a mesenchyme-derived pleiotrophic factor with mitogenic, motogenic and morphogenic activities on a number of different cell types. HGF effects are mediated through a specific tyrosine kinase, c-met, and aberrant HGF and c-met expression are frequently observed in a variety of tumors. See, e.g., Maulik et al., Cytokine & Growth Factor Reviews (2002), 13:41-59; Danilkovitch-Miagkova & Zbar, J. Clin. Invest. (2002), 109(7):863-867. Regulation of the HGF/c-Met signaling pathway is implicated in tumor progression and metastasis. See, e.g., Trusolino & Comoglio, Nature Rev. (2002), 2:289-300.

phosphorylation and downstream signaling through Gabl and Grb2/Sos mediated PB-kinase and Ras/MAPK activation respectively, which drives cell motility and proliferation (Furge et al., Oncogene (2000), 19, 5582-5589; Hartmann et al., J Biol Chem (1994), 269, 21936-21939; Ponzetto et al., J Biol Chem (1996), 271, 141 19-14123; Royal and Park, J Biol Chem (1995), 270, 27780-27787). Met was shown to be transforming in a carcinogen-treated osteosarcoma cell line (Cooper et al., Nature (1984), 311, 29-33; Park et al., Cell (1986), 45, 895-904). Met overexpression or gene-amplification has been observed in a variety of human cancers. For example, Met protein is overexpressed at least 5-fold in colorectal cancers and reported to be gene-amplified in liver metastasis (Di Renzo et al., Clin Cancer Res (1995), 1, 147-154; Liu et al., Oncogene (1992), 7, 181-185). Met protein is also reported to be overexpressed in oral squamous cell carcinoma, hepatocellular carcinoma, renal cell carcinoma, breast carcinoma, and lung carcinoma (Jin et al., Cancer (1997), 79, 749-760; Morello et al., J Cell Physiol (2001), 189, 285-290; Natali et al., Int J Cancer (1996), 69, 212-217; Olivero et al., Br J Cancer (1996), 74, 1862-1868; Suzuki et al., Br J Cancer (1996), 74, 1862-1868). In addition, overexpression of mRNA has been observed in hepatocellular carcinoma, gastric carcinoma, and colorectal carcinoma (Boix et al., Hepatology (1994), 19, 88-91; Kuniyasu et al., Int J Cancer (1993), 55, 72-75; Liu et al., Oncogene (1992), 7, 181-185).

A number of mutations in the kinase domain of Met have been found in renal papillary carcinoma which leads to constitutive receptor activation (Olivero et al., Int J Cancer (1999), 82, 640-643; Schmidt et al., Nat Genet (1997), 16, 68-73; Schmidt et al., Oncogene (1999), 18, 2343-2350). These activating mutations confer constitutive Met tyrosine phosphorylation and result in MAPK activation, focus formation, and tumorigenesis (Jeffers et al., Proc Natl Acad Sci U S A (1997), 94, 11445-11450). In addition, these mutations enhance cell motility and invasion (Giordano et al., Faseb J (2000), 14, 399-406; Lorenzato et al., Cancer Res (2002), 62, 7025-7030). HGF-dependent Met activation in transformed cells mediates increased motility, scattering, and migration which eventually leads to invasive tumor growth and metastasis (Jeffers et al., Mol Cell Biol (1996), 16, 1115-1125; Meiners et al., Oncogene (1998), 16, 9-20).

Met has been shown to interact with other proteins that drive receptor activation, transformation, and invasion. In neoplastic cells, Met is reported to interact with α6β4 integrin, a receptor for extracellular matrix (ECM) components such as laminins, to promote HGF-dependent invasive growth (Trusolino et al., Cell (2001), 107, 643-654). In addition, the extracellular domain of Met has been shown to interact with a member of the semaphorin family, plexin Bl, and to enhance invasive growth (Giordano et al., Nat Cell Biol (2002), 4, 720-724). Furthermore, CD44v6, which has been implicated in tumorigenesis and metastasis, is also reported to form a complex with Met and HGF and result in Met receptor activation (Orian-Rousseau et al., Genes Dev (2002), 16, 3074-3086).
Met is a member of the subfamily of receptor tyrosine kinases (RTKs) which include Ron and Sea (Maulik et al., Cytokine Growth Factor Rev (2002), 13, 41-59). Prediction of the extracellular domain structure of Met suggests shared homology with the semaphorins and plexins. The N-terminus of Met contains a Sema domain of approximately 500 amino acids that is conserved in all semaphorins and plexins. The semaphorins and plexins belong to a large family of secreted and membrane-bound proteins first described for their role in neural development (Van Vactor and Lorenz, Curr Bio (1999),1 9, R201-204). However, more recently semaphorin overexpression has been correlated with tumor invasion and metastasis. A cysteine-rich PSI domain (also referred to as a Met Related Sequence domain) found in plexins, semaphorins, and integrins lies adjacent to the Sema domain followed by four IPT repeats that are immunoglobulin-like regions found in plexins and transcription factors. A recent study suggests that the Met Sema domain is sufficient for HGF and heparin binding (Gherardi et al., Proc Natl Acad Sci U S A (2003), 100(21):12039-44).

As noted above, the Met receptor tyrosine kinase is activated by its cognate ligand HGF and receptor phosphorylation activates downstream pathways of MAPK, PI-3 kinase and PLC-γ (L. Trusolino and P. M. Comoglio, Nat Rev Cancer 2, 289 (2002); C. Birchmeier et al., Nat Rev Mol Cell Biol 4, 915 (2003)). Phosphorylation of Y1234/Y1235 within the kinase domain is critical for Met kinase activation while Y1349 and Y1356 in the multisubstrate docking site are important for binding of src homology-2 (SH2), phosphotyrosine binding (PTB), and Met binding domain (MBD) proteins (C. Ponzetto et al., Cell 77, 261 (1994); K. M. Weidner et al., Nature 384, 173 (1996); G. Pelicci et al., Oncogene 10, 1631 (1995)) to mediate activation of downstream signaling pathways.

An additional juxtamembrane phosphorylation site, Y1003, has been well characterized for its binding to the tyrosine kinase binding (TKB) domain of the Cbl E3-ligase (P. Peschard et al., Mol Cell 8, 995 (2001); P. Peschard, N. Ishiyama, T. Lin, S. Lipkowitz, M. Park, J Biol Chem 279, 29565 (2004)). Cbl binding is reported to drive endophilin-mediated receptor endocytosis, ubiquitination, and subsequent receptor degradation (A. Petrelli et al., Nature 416, 187 (2002)). This mechanism of receptor downregulation has been described previously in the EGFR family that also harbor a similar Cbl binding site (K. Shtiegalman, Y. Yarden, Semin Cancer Biol 13, 29 (2003); M. D. Marmor, Y. Yarden, Oncogene 23, 2057 (2004); P. Peschard, M. Park, Cancer Cell 3, 519 (2003)). Dysregulation of Met and HGF have been reported in a variety of tumors. Ligand-driven Met activation has been observed in several cancers. Elevated serum and intra-tumoral HGF is observed in lung, breast cancer, and multiple myeloma (J. M. Siegfried et al., Ann Thorac Surg 66, 1915 (1998); P. C. Ma et al., Anticancer Res 23, 49 (2003); B. E. Elliott et al. Can J Physiol Pharmacol 80, 91 (2002); C. Seidel, et al, Med Oncol 15, 145 (1998)). Overexpression of Met and/or HGF, Met amplification or mutation has been reported in various cancers such as colorectal, lung, gastric, and kidney cancer and is thought to drive ligand-independent receptor activation (C. Birchmeier et al, Nat Rev Mol Cell Biol 4, 915 (2003); G. Maulik et al., Cytokine Growth Factor Rev 13, 41 (2002)). Additionally, inducible overexpression of Met in a liver mouse model gives rise to hepatocellular carcinoma demonstrating
that receptor overexpression drives ligand independent tumorigenesis (R. Wang, et al, J Cell Biol 153, 1023 (2001)). The most compelling evidence implicating Met in cancer is reported in familial and sporadic renal papillary carcinoma (RPC) patients. Mutations in the kinase domain of Met that lead to constitutive activation of the receptor were identified as germline and somatic mutations in RPC (L. Schmidt et al., Nat Genet 16, 68 (1997)). Introduction of these mutations in transgenic mouse models leads to tumorigenesis and metastasis. (M. Jeffers et al., Proc Natl Acad Sci USA 94, 11445 (1997)).

The epidermal growth factor receptor (EGFR) family comprises four closely related receptors (HER1/EGFR, HER2, HER3 and HER4) involved in cellular responses such as differentiation and proliferation. Over-expression of the EGFR kinase, or its ligand TGF-alpha, is frequently associated with many cancers, including breast, lung, colorectal, ovarian, renal cell, bladder, head and neck cancers, glioblastomas, and astrocytomas, and is believed to contribute to the malignant growth of these tumors. A specific deletion-mutation in the EGFR gene (EGFRvIII) has also been found to increase cellular tumorigenicity. Activation of EGFR stimulated signaling pathways promote multiple processes that are potentially cancer-promoting, e.g. proliferation, angiogenesis, cell motility and invasion, decreased apoptosis and induction of drug resistance. Increased HER1/EGFR expression is frequently linked to advanced disease, metastases and poor prognosis. For example, in NSCLC and gastric cancer, increased HER1/EGFR expression has been shown to correlate with a high metastatic rate, poor tumor differentiation and increased tumor proliferation.

Mutations which activate the receptor's intrinsic protein tyrosine kinase activity and/or increase downstream signaling have been observed in NSCLC and glioblastoma. However the role of mutations as a principle mechanism in conferring sensitivity to EGF receptor inhibitors, for example erlotinib (TARCEVA®) or gefitinib, has been controversial. Mutant forms of the full length EGF receptor have been reported to predict responsiveness to the EGF receptor tyrosine kinase inhibitor gefitinib (Paez, J. G. et al. (2004) Science 304:1497-1500; Lynch, T. J. et al. (2004) N. Engl. J Med. 350:2129-2139). Cell culture studies have shown that cell lines which express such mutant forms of the EGF receptor (i.e. H3255) were more sensitive to growth inhibition by the EGF receptor tyrosine kinase inhibitor gefitinib, and that much higher concentrations of gefitinib was required to inhibit the tumor cell lines expressing wild type EGF receptor. These observations suggests that specific mutant forms of the EGF receptor may reflect a greater sensitivity to EGF receptor inhibitors, but do not identify a completely non-responsive phenotype.

Despite the significant advancement in the treatment of cancer, improved therapies are still being sought.

**SUMMARY OF THE INVENTION**

The present invention provides combination therapies for treating a pathological condition, such as cancer, wherein a c-met antagonist is combined with an EGFR antagonist, thereby providing
significant anti-tumor activity.

In one aspect, the invention provides methods of treating a cancer in a subject, comprising administering to the subject a therapeutically effective amount of a c-met antagonist and an EGFR antagonist.

Examples of c-met antagonists include, but are not limited to, soluble c-met receptors, soluble HGF variants, aptamers or peptidomimetics that are specific to c-met or HGF, c-met small molecules, anti-c-met antibodies and anti-HGF antibodies. In some embodiment, the c-met antagonist is an anti-c-met antibody.

In one embodiment, the anti-c-met antibody comprises a heavy chain variable domain comprising one or more of CDR1-HC, CDR2-HC and CDR3-HC sequence depicted in Figure 7 (SEQ ID NO: 13-15). In some embodiments, the antibody comprises a light chain variable domain comprising one or more of CDR1-LC, CDR2-LC and CDR3-LC sequence depicted in Figure 7 (SEQ ID NO: 5-7). In some embodiments, the heavy chain variable domain comprises FR1-HC, FR2-HC, FR3-HC and FR4-HC sequence depicted in Figure 7 (SEQ ID NO: 9-12). In some embodiments, the light chain variable domain comprises FR1-LC, FR2-LC, FR3-LC and FR4-LC sequence depicted in Figure 7 (SEQ ID NO: 1-4). In some embodiments, the anti-c-met antibody is monovalent and comprises an Fc region. In some embodiments, the antibody comprises Fc sequence depicted in Figure 7 (SEQ ID NO: 17).

In some embodiments, the antibody is monovalent and comprises a Fc region, wherein the Fc region comprises a first and a second polypeptide, wherein the first polypeptide comprises the Fc sequence depicted in Figure 7 (SEQ ID NO: 17) and the second polypeptide comprises the Fc sequence depicted in Figure 8 (SEQ ID NO: 18).

In one embodiment, the anti-c-met antibody comprises (a) a first polypeptide comprising a heavy chain variable domain having the sequence:

```
QVQLQSGPEVLRRPGASVKMSCTASQGVTFTSYWGLHWVKQRRPGGGEWSWIGMDPSNSDTRFN
PNFKDKATLNVDRSSSTAYMLSSLTASAVYYCATGTYVSPQWYGQGTSTTVSS
(SEQ ID NO: 19), CHI sequence depicted in Figure 7 (SEQ ID NO: 16), and the Fc sequence depicted in Figure 7 (SEQ ID NO: 17); and (b) a second polypeptide comprising a light chain variable domain having the sequence:
DIMMSQPSLTVSVGAKVTWSCKSSQSLYTSQKNNLAWYQRQKPGQSPKLQIYWASTRES
GVPDRTGSGSGLTDALTTSVKAAGAVYCCQYYAPWFGGKTLEIK (SEQ ID NO: 20),
``` and CL1 sequence depicted in Figure 7 (SEQ ID NO: 8); and (c) a third polypeptide comprising the Fc sequence depicted in Figure 8 (SEQ ID NO: 18).

In one aspect, the anti-c-met antibody comprises at least one characteristic that promotes heterodimerization, while minimizing homodimerization, of the Fc sequences within the antibody fragment. Such characteristic(s) improves yield and/or purity and/or homogeneity of the immunoglobulin populations. In one embodiment, the antibody comprises Fc mutations constituting
"knobs" and "holes" as described in WO2005/063816. For example, a hole mutation can be one or more of T366A, L368A and/or Y407V in an Fc polypeptide, and a cavity mutation can be T366W.

In some embodiments, the c-met antagonist is SGX-523, PF-02341066, INJ-38877605, BMS-698769, PHA-665,752, SU5416, SU 1274, XL-880, MGCD265, ARQ 197, MP-470, AMG 102, antibody 223C4 or humanized antibody 223C4 (WO2009/007427), L2G7, NK4, XL-1 84, MP-470, or Comp-1.

C-met antagonists can be used to reduce or inhibit one or more aspects of HGF/c-met-associated effects, including but not limited to c-met activation, downstream molecular signaling (e.g., mitogen activated protein kinase (MAPK) phosphorylation, AKT phosphorylation, c-met phosphorylation, PI3 kinase mediated signaling), cell proliferation, cell migration, cell survival, cell morphogenesis and angiogenesis. These effects can be modulated by any biologically relevant mechanism, including disruption of ligand (e.g., HGF) binding to c-met, c-met phosphorylation and/or c-met multimerization.

Examples of EGFR antagonists include antibodies and small molecules that bind to EGFR.

In a particular embodiment, the EGFR antagonist has a general formula I:
in accordance with US 5,757,498, incorporated herein by reference, wherein:

m is 1, 2, or 3;

each \( R^1 \) is independently selected from the group consisting of hydrogen, halo, hydroxy, hydroxyamino, carboxy, nitro, guanidino, ureido, cyano, trifluoromethyl, and -\((\text{C}_4\) alkylene)-W-(phenyl) wherein W is a single bond, O, S or NH;

or each \( R^1 \) is independently selected from \( R^9 \) and \( \text{C}_4 \) alkyl substituted by cyano, wherein \( R^9 \) is selected from the group consisting of \( R^5 \), -OR\(^5 \), -NR\(^6\)R\(^6\), -C(O)R\(^7\), -NHOR\(^5\), -OC(O)R\(^6\), cyano, A and -YR\(^5\); \( R^5 \) is \( \text{C}_4 \) alkyl; \( R^6 \) is independently hydrogen or \( R^5 \); \( R^7 \) is \( R^5 \), -OR\(^5\) or -NR\(^6\)R\(^6\); A is selected from piperidino, morpholino, pyrrolidino, 4-R\(^6\)-piperazin-1-yl, imidazol-1-yl, 4-pyridon-1-yl, -\((\text{C}_4 \) alkylene)(C02H), phenoxy, phenyl, phenylsulfanyl, \( \text{C}_2\)C\(_4\) alkenyl, and -(\(\text{C}_4 \) alkylene)C(O)NR\(^6\)R\(^6\); and \( Y \) is S, SO, or SO\(_2\); wherein the alkyl moieties in \( R^5 \), -OR\(^5\) and -NR\(^6\)R\(^6\) are optionally substituted by one to three halo substituents and the alkyl moieties in \( R^5 \), -OR\(^5\) and -NR\(^6\)R\(^6\) are optionally substituted by 1 or 2 \( R^9 \) groups, and wherein the alkyl moieties of said optional substituents are optionally substituted by halo or \( R^9 \), with the proviso that two heteroatoms are not attached to the same carbon atom;

or each \( R^1 \) is independently selected from -NHSO\(_2\)R\(^5\), phthalimido-(\(\text{Q}\)C\(_4\))-alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido, 2-oxopyrrolidin-1-yl, 2,5-dioxopyrrolidin-1-yl, and R\(^m\)-(\(\text{C}_2\)C\(_4\))-alkanoylamino wherein R\(^m\) is selected from halo, -OR\(^5\), C\(_2\)C\(_4\) alkanoyloxy, -C(O)R\(^7\) and -NR\(^6\)R\(^6\); and wherein said -NHSO\(_2\)R\(^5\), phthalimido-(\(\text{Q}\)C\(_4\))-alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido, 2-oxopyrrolidin-1-yl, 2,5-dioxopyrrolidin-1-yl, and R\(^m\)-(\(\text{C}_2\)C\(_4\))-alkanoylamino R\(^1\) groups are optionally substituted by 1 or 2 substituents independently selected from halo, Cp\(_4\) alkyl, cyano, methanesulfonyle and Q\(_4\)C\(_4\) alkoxy;

or two \( R^1 \) groups are taken together with the carbons to which they are attached to form a 5-8 membered ring that includes 1 or 2 heteroatoms selected from O, S and N;

\( R^2 \) is hydrogen or Q\(_4\)C\(_8\) alkyl optionally substituted by 1 to 3 substituents independently selected from halo, C\(_1\)C\(_4\) alkoxy, -NR\(^6\)R\(^6\), and -SO\(_2\)R\(^5\);

n is 1 or 2 and each \( R^3 \) is independently selected from hydrogen, halo, hydroxy, Q\(_4\)C\(_8\) alkyl, -NR\(^6\)R\(^6\), and Q\(_4\)C\(_4\) alkoxy, wherein the alkyl moieties of said \( R^3 \) groups are optionally substituted by 1 to 3 substituents independently selected from halo, Cp\(_4\) alkoxy, -NR\(^6\)R\(^6\), and -SO\(_2\)R; and
R₄ is azido or -(ethynyl)-R₁₁ wherein R₁₁ is hydrogen or Ci-Ce alkyl optionally substituted by hydroxy, -OR₆, or -NR₆R₆.

In a particular embodiment, the EGFR antagonist is a compound according to formula I selected from the group consisting of:

(6,7-dimethoxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-[3-(3'-hydroxypropyn-1-yl)phenyl]-amine; [3-(2'-(aminomethyl)-ethyl)phenyl]-{6,7-dimethoxyquinazolin-4-yl}-amine; (3-ethynylphenyl)-(6-nitroquinazolin-4-yl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(4-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethynyl-2-methylphenyl)-amine; (6-amoquinazolin-4-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(6-methanesulfonylaminoquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6,7-methylenedioxyquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-aminoquinazolin-4-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(6-methansulfonylaminoquinazolin-4-yl)-amine; (3-ethynylphenyl)-(7-nitroquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-(4'-toluenesulfonylamo)quinazolin-4-yl)-amine; (3-ethynylphenyl)-[6-(2'-phthalimido-ethyl)-sulfonylamino]quinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-guanidinoquinazolin-4-yl)-amine; (7-aminoquinazolin-4-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(7-methoxyquinazolin-4-yl)-amine; (6-carboxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; (7-carboxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; [6,7-bis(2-methoxyethoxy)quinazolin-4-yl]-amine; (3-azidophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-azido-5-chlorophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (4-azidophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-methanesulfonylquinazolin-4-yl)-amine; (6-ethansulfanyl-quinazolin-4-yl)-(3-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethynyl-4-fluoro-phenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethynyl-2-methylphenyl)-amine; [6,7-bis-(2-chloro-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [6,7-bis-(2-acetoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [7-(2-chloro-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [7-(2-acetoxy-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [6-(2-acetoxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [7-(2-chloro-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [7-(2-acetoxy-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [6-(2-acetoxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynylphenyl)-amine; [6,7-diethoxyquinazolin-1-yl)-(3-ethynylphenyl)-amine; (6,7-diethoxyquinazolin-1-yl)-(3-ethynyl-2-methyl-phenyl)-amine; [6,7-bis-
(2-methoxy-ethoxy)-quinazolin-1-yl)-(3-ethynyl-2-methyl-phenyl)-amine; (3-ethynylphenyl)-[6-(2-hydroxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-1-yl]-amine; [6,7-bis-(2-hydroxy-ethoxy)-quinazolin-1-yl]-amine; 2-[4-(3-ethynyl-phenylamino)-6-(2-methoxy-ethoxy)-quinazolin-7-yloxy]-ethanol; (6,7-dipropoxy-quinazolin-4-yl)-(3-ethynyl-phenyl)-amine; (6,7-diethoxy-quinazolin-4-yl)-(3-ethynyl-5-fluoro-phenyl)-amine; (6,7-diethoxy-quinazolin-4-yl)-(3-ethynyl-2-methyl-phenyl)-amine; (6,7-diethoxy-quinazolin-4-yl)-(5-ethynyl-2-methyl-phenyl)-amine; (6,7-diethoxy-quinazolin-4-yl)-(3-ethynyl-4-methyl-phenyl)-amine; (6-aminomethyl-7-methoxy-quinazolin-4-yl)-(3-ethynyl-phenyl)-amine; (6-aminomethyl-7-methoxy-quinazolin-4-yl)-(3-ethynylphenyl)-amine; (6-aminocarboxylethyl-7-methoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethynyphenyl)-amine; and (6-amino-quinazolin-1-yl)-(3-ethynyphenyl)-amine.

In a particular embodiment, the EGFR antagonist of formula I is N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine. In a particular embodiment, the EGFR antagonist N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is in HCl salt form. In another particular embodiment, the EGFR antagonist N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is in a substantially homogeneous crystalline polymorph form (described as polymorph B in WO 01/34,574) that exhibits an X-ray powder diffraction pattern having characteristic peaks expressed in degrees 2-theta at approximately 6.26, 12.48, 13.39, 16.96, 20.20, 21.10, 22.98, 24.46, 25.14 and 26.91. Such polymorph form of N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is referred to as Tarceva™ as well as OSI-774, CP-358774 and erlotinib.

EGFR antagonists can be used to reduce or inhibit one or more aspects of EGFR-EGFR ligand-associated effects, including but not limited to EGFR activation, downstream molecular signaling, cell proliferation. These effects can be modulated by any biologically relevant mechanism, including disruption of ligand binding to EGFR, and disruption of EGFR phosphorylation.

Methods of the invention can be used to affect any suitable pathological state. For example, methods of the invention can be used for treating different cancers, both solid tumors and soft-tissue
tumors alike. Non-limiting examples of cancers amendable to the treatment of the invention include breast cancer, colorectal cancer, rectal cancer, non-small cell lung cancer (NSCLC), non-Hodgkins lymphoma (NHL), renal cell cancer, prostate cancer, liver cancer, pancreatic cancer, soft-tissue sarcoma, kaposi’s sarcoma, carcinoid carcinoma, head and neck cancer, glioblastoma, melanoma, ovarian cancer, gastric cancer, mesothelioma, and multiple myeloma. In certain aspects, the cancers are metastatic. In other aspects, the cancers are non-metastatic.

In one embodiment, an anti-c-met antibody and erlotinib are used in combination therapies of cancers such as non-small cell lung carcinoma.

In certain embodiments, the cancer is not an EGFR antagonist (e.g., erlotinib or gefitinib) resistant cancer. In certain embodiments, the cancer is not an erlotinib or gefitinib resistant cancer.

In certain embodiments, the cancer is not a tyrosine kinase inhibitor-resistant cancer. In certain embodiments, the cancer is not a small molecule EGFR tyrosine kinase inhibitor-resistant cancer.

In certain embodiments, the cancer displays c-met and/or EGFR expression, amplification, or activation. In certain embodiments, the cancer does not display c-met and/or EGFR expression, amplification, or activation. In certain embodiments, the cancer displays c-met amplification. In certain embodiments, the cancer displays c-met amplification and EGFR amplification.

In certain embodiments, the cancer displays a wildtype EGFR gene. In certain embodiments, the cancer displays a wildtype EGFR gene and c-met amplification and/or c-met mutation.

In certain embodiments, the cancer displays EGFR mutation. Mutations can be located in any portion of an EGFR gene or regulatory region associated with an EGFR gene. Exemplary EGFR mutations include, for example, mutations in exon 18, 19, 20 or 21, mutations in the kinase domain, G719A, L858R, E746K, L747S, E749Q, A750P, A755V, V765M, S768L, L858P, E746-R748 del, R748-P753 del, M766-A767 AI ins, S768- V769 SVA ins, P772-H773 NS ins, 2402OC, 2482OA, 2486T>C, 2491 G>C, 2494OC, 251 0OT, 2539OA, 2549OT, 2563OT, 2819T>C, 2482-2490 del, 2486-2503 del, 2544-2545 ins GCCATA, 2554-2555 ins CCAGCGTG, or 2562-2563 ins AACTCC. Other examples of EGFR activating mutations are known in the art (see e.g., US Patent Publication No. 2005/0272083). In certain embodiments, the cell or cell line does not comprise a T790M mutation in the EGFR gene.

In certain embodiments, the cancer displays c-met and/or EGFR activation. In certain embodiments, the cancer does not display c-met and/or EGFR activation.

In certain embodiments, the cancer displays constitutive c-met and/or EGFR activation. In some embodiments, the constitutive EGFR comprises a mutation in the tyrosine kinase domain. In certain embodiments, the cancer does not display constitutive c-met and/or EGFR activation.

In certain embodiments, the cancer displays ligand-independent c-met and/or EGFR activation. In certain embodiments, the cancer does not display ligand-independent c-met and/or EGFR activation.
The c-met antagonist can be administered serially or in combination with the EGFR antagonist, either in the same composition or as separate compositions. The administration of the c-met antagonist and the EGFR antagonist can be done simultaneously, e.g., as a single composition or as two or more distinct compositions, using the same or different administration routes. Alternatively, or additionally, the administration can be done sequentially, in any order. Alternatively, or additionally, the steps can be performed as a combination of both sequentially and simultaneously, in any order. In certain embodiments, intervals ranging from minutes to days, to weeks to months, can be present between the administrations of the two or more compositions. For example, the EGFR antagonist may be administered first, followed by the c-met antagonist. However, simultaneous administration or administration of the c-met antagonist first is also contemplated. Accordingly, in one aspect, the invention provides methods comprising administration of a c-met antagonist (such as an anti-c-met antibody), followed by administration of an EGFR antagonist (such as erlotinib (TARCEVA®)). In certain embodiments, intervals ranging from minutes to days, to weeks to months, can be present between the administrations of the two or more compositions.

In one aspect, the invention provides a composition for use in treating a cancer comprising an effective amount of a c-met antagonist and a pharmaceutically acceptable carrier, wherein said use comprises simultaneous or sequential administration of an EGFR antagonist. In some embodiments, the c-met antagonist is an anti-c-met antibody. In some embodiments, the EGFR antagonist is erlotinib (TARCEVA®).

In one aspect, the invention provides a composition for use in treating a cancer comprising an effective amount of a c-met antagonist and a pharmaceutically acceptable carrier, wherein said use comprises simultaneous or sequential administration of an EGFR antagonist. In some embodiments, the c-met antagonist is an anti-c-met antibody. In some embodiments, the EGFR antagonist is erlotinib (TARCEVA®).

Depending on the specific cancer indication to be treated, the combination therapy of the invention can be combined with additional therapeutic agents, such as chemotherapeutic agents, or additional therapies such as radiotherapy or surgery. Many known chemotherapeutic agents can be used in the combination therapy of the invention. Preferably those chemotherapeutic agents that are standard for the treatment of the specific indications will be used. Dosage or frequency of each therapeutic agent to be used in the combination is preferably the same as, or less than, the dosage or frequency of the corresponding agent when used without the other agent(s).

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIGURES IA and IB: Confirmation of EGFR and MET mRNA coexpression in NSCLC cell lines and primary tumors by qRT-PCR. Expression of EGFR and AffiTM RNA was determined by quantitative RT-PCR in a panel of NSCLC cell lines (IA) or frozen primary NSCLC tumor lysates (IB). EGFR and MET mRNA levels were positively correlated in cell lines (p=0.59, p<0.0001) and primary NSCLC specimens (p=0.48, p=0.0003).
FIGURE 2: EBC-I shMet 4.12 cells (shMet 4.12) containing a tetracycline inducible shRNA directed against c-met or control shRNA directed against GFP (shGFP2) were grown in control media (Con) or media with 0.1ug/ml tetracycline analog Doxycycline (Dox) for 48 hours. After serum-starvation for 2 hours, cells were untreated (-) or treated with TGFα (T, 20nM) or Heregulin b1 (Hrg, 2nM) for 20 minutes. Whole cell lysates were evaluated for expression of total and phospho-proteins as indicated. Beta-Actin (β-Actin) was detected to show equivalent loading between lanes.

FIGURE 3: NSCLC H441 cells containing an inducible shRNA directed against c-met or control shRNA directed against GFP were grown in control media or media containing 0.1ug/ml Dox (Dox) for 48 hours. After serum-starvation for 2 hours, cells were untreated (-) or treated with TGFα (T) or Heregulin b1 (H) for 20 minutes. Beta-Actin (β-Actin) (4th panel) was detected to show equivalent loading between lanes.

FIGURE 4: Combination efficacy of erlotinib with shRNA knockdown of c-met in the EBC-I NSCLC xenograft model. EBC-I-shMet-4.5 tumors were established in nude (CRL nu/nu) animals and then treated with either methylcellulose tween (MCT) vehicle plus drinking water containing 5% sucrose (Sue) (PO, QD when arrows indicate), MCT plus 1 mg/mL doxycycline (Dox) in the drinking water formulated in 5% sucrose (100 mg/kg; PO, QD, where arrows indicate), erlotinib plus drinking water containing 5% sucrose (PO, QD where arrows indicate), or erlotinib plus 1 mg/mL doxycycline in the drinking water formulated in 5% sucrose (PO, QD where arrows indicate). Oral dosing was done on days indicated by the arrows. Sucrose or Dox water was maintained throughout the study with bottles being interchanged every 2-3 days. Tumor volumes and SEM were calculated as described in the Examples.

FIGURE 5: Combination efficacy of MetMAb with erlotinib in the NCI-H596 hu-HGF-Tg-C3H-SCID xenograft model. NCI-H596 tumors were grown in hu-HGF-Tg-C3H-SCID or C3H-SCID littermate control animals and treated with either Captisol vehicle (PO, QD, x2 weeks), erlotinib (closed circles, short dashed line; 150 mg/kg, PO, QD, x2 weeks), MetMAb (30 mg/kg, IP, once), or the combination of MetMAb plus erlotinib at the same doses and schedules. Dosing was as indicated on the bottom of chart for MetMAb (open arrow head) and erlotinib or vehicle (closed arrow heads). Tumor measurements were taken by caliper twice to three times per week for about 9 weeks or until groups were removed from the study due to large tumor sizes within the group. Tumor volumes and SEM were calculated as described in the Examples.

FIGURE 6: Time to tumor doubling (TTD) measurements, defined as the time it took for tumors to double in size, were calculated for each group and used to generate Kaplan-Meier survival curves. The combination of MetMAb plus erlotinib showed a dramatic improvement in tumor progression with a mean TTD of 49.5 (± 2.6) days versus 17.8 (± 2.2) days for the MetMAb-treated group, 9.5 (± 1.2) days for the erlotinib-treated group, and 9.5 (± 1.2) days for vehicle control group. The curves for the vehicle and erlotinib group were perfectly overlayed.

FIGURE 7: depicts amino acid sequences of the framework regions (FR), hypervariable regions...
(HVR), first constant domain (CL or CH1) and Fc region (Fc) of one embodiment of an anti-c-met antibody. The Fc sequence depicted comprises mutations T366S, L368A and Y407V, as described in WO 2005/063816.

FIGURE 8: depicts sequence of an Fc polypeptide comprising mutation T366W, as described in WO 2005/063816. In one embodiment, an Fc polypeptide comprising this sequence forms a complex with an Fc polypeptide comprising the Fc sequence of Fig. 7 to generate an Fc region.

FIGURES 9A-E: C-met activity regulates expression of EGFR ligands. A) Treatment with HGF induced upregulation of EGFR ligands in HGF-responsive NSCLC cell lines. Hop92 or NCI-H596 cells were serum-starved overnight, and then untreated (No HGF) or treated with HGF (50 ng/ml) for 6 hours (HGF). RNA from cells +/- HGF treatment underwent microarray analyses as described in the Examples. RMA= relative microarray. B) C-met knock-down decreased expression of EGFR ligands in ligand-independent NSCLC cell line EBC-I. Clones stably expressing shRNA directed against c-met (clones 3-15 and 4-12) were untreated (noDox) or treated with Doxycycline (Dox) for 24 or 48 hours RNA from cells underwent microarray analyses as described in the Examples. C) EBCshMet4-12 cell stably expressing shRNA directed against c-met were untreated (No Dox) or treated with Dox (Dox) for 24 hours without HGF (No HGF) or with HGF (100ng/ml) for 2 hours. RNA from the cells underwent microarray analyses as described in the Examples. D) EBCshMet4-12 cells stably expressing shRNA directed against c-met and control cells stably expressing shGFP2 were untreated (No Dox) or treated with Dox (Dox) for 24 hours. RNA from the cells underwent microarray analyses as described in the Examples. E) Tumors from EBCshMet-4.12 or EBCshMet-3.15 cells were established in nude (CRL nu-nu) animals, and mice were given drinking water with 1mg/ml Dox (Dox) in 5% sucrose or 5% sucrose alone. After 3 days, TGFα levels in tumor lysates were evaluated by ELISA.

FIGURES IOA-C: (A) EBCshMet 4.12 or EBCshGFP2 cells were untreated (-) or treated with Dox (+) for 24, 48 or 72 hours. Protein lysates were evaluated for c-met, pEGFR or Her3 by western blotting. (B) EBCshMet 4.12 cells were treated with Dox (100ng/ml) for 48 hours and analyzed by FACS for cell surface Her3. (C) Mice with EBCshMet 4.12 tumors were given drinking water with 1mg/ml Dox in 5% sucrose (Dox) or 5% sucrose alone (Sucrose) for 3 days. Tumors lysates were evaluated for Her3 protein by western blotting.

FIGURE 11: EBC-I shMet cells (3.15 or 4.5 or 4.12) were untreated (-) or treated with 100ng/ml Dox (+) for 96 hours alone or with HGF (5 or 100ng/ml) or TGFα (1 or 50nM) added 48 hours after initiation of Dox treatment. Cell number was evaluated using Cell Titer Glo.

FIGURE 12: A time course experiment was performed with NCI-H596 cells in the presence (right panels) or absence (left panels) of HGF. Cell lysates were prepared at 10 minutes (10'), 24 hours, 48 hours or 72 hours (hr) post-stimulation and western blots were performed to detect total c-met (top panel), phospho-EGFR (2nd panel), and total EGFR (3rd panel). Beta-Actin (β-Actin) (4th panel) was detected to show equivalent loading between lanes.
FIGURE 13: NCI-H596 cells were plated in the presence of no ligands, TGF-α alone, TGF-α + HGF or HGF alone. Cell lysates were prepared at 10 minutes (10 min) and 24 hours (hr) post-stimulation, and immunoprecipitations (IP) for c-met were performed followed by western blotting for phospho-tyrosine (4G10; top panel), c-met (2nd panel), and EGFR (3rd panel). The phospho-tyrosine blots shows activation of EGFR (top band) and c-met (bottom band) in a ligand-dependent manner, attenuating after 24 hours. C-met immunoprecipitation brought down EGFR in all conditions regardless of activation status of EGFR or c-met.

FIGURE 14: Viability assays were performed with NCI-H596 cells to evaluate response of cells to erlotinib in the presence of TGFα and varying concentrations of HGF as indicated. Reduction in relative response to erlotinib was detected as HGF levels increased from 0.5 ng/ml to 50 ng/ml.

FIGURE 15: Viability assays were performed with NCI-H596 cells in the presence of TGF α and HGF (50 ng/ml), with or without MetMAb (1 µM), and varying concentrations of erlotinib. Data are represented as percent of untreated controls. Untreated control values are shown as individual points on top left of the figure.

FIGURE 16: Combination treatment with MetMAb and Erlotinib resulted in more effective inhibition of phospho-Akt and phospho-ERKI/2. Human-HGF-transgenic-SCID (hu-HGF-Tg-SCID) mice bearing NCI-H596 tumors were treated with vehicles (MetMAb buffer (100 µL, IP) and methylcellulose tween (MCT, 100 µL, PO), MetMAb ((30 mg/kg, IP, once) and MCT), erlotinib ((100 mg/kg in MCT, 100 µL, PO) and MetMAb buffer (100 µL, IP)) or MetMAb and erlotinib (same dosing as described for each). MetMAb (or buffer) was dosed at time zero (t 0 hrs), erlotinib (or MCT) was dosed at time eighteen hours (t 18 hrs), mice were euthanized and tumors were collected at time twenty-four hours (t 24 hrs). Tumor lysates were analyzed for total and phospho-proteins by both direct Western blotting and immunoprecipitation followed by Western blot. Abbreviations: pTyr = phospho-tyrosine, EGFR = epidermal growth factor receptor, ERK (extracellular signal-regulated kinase-1 and 2. Beta-Actin (β-Actin) was detected to show equivalent loading between lanes.

FIGURES 17A and 17B: diagrammatically depicts some of the results described in the present application.

DETAILED DESCRIPTION

1. Definitions

The term "hepatocyte growth factor" or "HGF", as used herein, refers, unless indicated otherwise, to any native or variant (whether native or synthetic) HGF polypeptide that is capable of activating the HGF/c-met signaling pathway under conditions that permit such process to occur. The term "wild type HGF" generally refers to a polypeptide comprising the amino acid sequence of a naturally occurring HGF protein. The term "wild type HGF sequence" generally refers to an amino acid sequence found in a naturally occurring HGF. C-met is a known receptor for HGF through which HGF intracellular signaling is biologically eff ectuated.

The term "HGF variant" as used herein refers to a HGF polypeptide which includes one or
more amino acid mutations in the native HGF sequence. Optionally, the one or more amino acid
mutations include amino acid substitution(s).

A "native sequence" polypeptide comprises a polypeptide having the same amino acid
sequence as a polypeptide derived from nature. Thus, a native sequence polypeptide can have the
amino acid sequence of naturally-occurring polypeptide from any mammal. Such native sequence
polypeptide can be isolated from nature or can be produced by recombinant or synthetic means. The
term "native sequence" polypeptide specifically encompasses naturally-occurring truncated or
secreted forms of the polypeptide (e.g., an extracellular domain sequence), naturally-occurring variant
forms (e.g., alternatively spliced forms) and naturally-occurring allelic variants of the polypeptide.

A polypeptide "variant" means a biologically active polypeptide having at least about 80%
amino acid sequence identity with the native sequence polypeptide. Such variants include, for
instance, polypeptides wherein one or more amino acid residues are added, or deleted, at the N- or C-
terminus of the polypeptide. Ordinarily, a variant will have at least about 80% amino acid sequence
identity, more preferably at least about 90% amino acid sequence identity, and even more preferably
at least about 95% amino acid sequence identity with the native sequence polypeptide.

By "EGFR" (interchangeably termed "ErbBl", "HERI" and "epidermal growth factor
receptor") is meant the receptor tyrosine kinase polypeptide Epidermal Growth Factor Receptor which
is described in Ullrich et al, Nature (1984) 309:418425, alternatively referred to as Her-1 and the c-
erbB gene product, as well as variants thereof such as EGFRvIII. Variants of EGFR also include
deletional, substitutional and insertional variants, for example those described in Lynch et al (New

A "biological sample" (interchangeably termed "sample" or "tissue or cell sample")
embraces a variety of sample types obtained from an individual and can be used in a diagnostic or
monitoring assay. The definition encompasses blood and other liquid samples of biological origin,
solid tissue samples such as a biopsy specimen or tissue cultures or cells derived therefrom, and the
progeny thereof. The definition also includes samples that have been manipulated in any way after
their procurement, such as by treatment with reagents, solubilization, or enrichment for certain
components, such as proteins or polynucleotides, or embedding in a semi-solid or solid matrix for
sectioning purposes. The term "biological sample" encompasses a clinical sample, and also includes
cells in culture, cell supernatants, cell lysates, serum, plasma, biological fluid, and tissue samples. The
source of the biological sample may be solid tissue as from a fresh, frozen and/or preserved organ or
tissue sample or biopsy or aspirate; blood or any blood constituents; bodily fluids such as cerebral
spinal fluid, amniotic fluid, peritoneal fluid, or interstitial fluid; cells from any time in gestation or
development of the subject. In some embodiments, the biological sample is obtained from a primary
or metastatic tumor. The biological sample may contain compounds which are not naturally
intermixed with the tissue in nature such as preservatives, anticoagulants, buffers, fixatives, nutrients,
antibiotics, or the like.

A "c-met antagonist" (interchangeably termed "c-met inhibitor") is an agent that interferes with c-met activation or function. Examples of c-met inhibitors include c-met antibodies; HGF antibodies; small molecule c-met antagonists; c-met tyrosine kinase inhibitors; antisense and inhibitory RNA (e.g., shRNA) molecules (see, for example, WO2004/87207). Preferably, the c-met inhibitor is an antibody or small molecule which binds to c-met. In a particular embodiment, a c-met inhibitor has a binding affinity (dissociation constant) to c-met of about 1,000 nM or less. In another embodiment, a c-met inhibitor has a binding affinity to c-met of about 100 nM or less. In another embodiment, a c-met inhibitor has a binding affinity to c-met of about 50 nM or less. In a particular embodiment, a c-met inhibitor is covalently bound to c-met. In a particular embodiment, a c-met inhibitor inhibits c-met signaling with an IC50 of 1,000 nM or less. In another embodiment, a c-met inhibitor inhibits c-met signaling with an IC50 of 500 nM or less. In another embodiment, a c-met inhibitor inhibits c-met signaling with an IC50 of 50 nM or less.

As used herein, the term "c-met-targeted drug" refers to a therapeutic agent that binds to c-met and inhibits c-met activation. An example of a c-met targeted drug is MetMAb (OA5D5.v2).

"C-met activation" refers to activation, or phosphorylation, of the c-met receptor. Generally, c-met activation results in signal transduction (e.g. that caused by an intracellular kinase domain of a c-met receptor phosphorylating tyrosine residues in c-met or a substrate polypeptide). C-met activation may be mediated by c-met ligand (HGF) binding to a c-met receptor of interest. HGF binding to c-met may activate a kinase domain of c-met and thereby result in phosphorylation of tyrosine residues in the c-met and/or phosphorylation of tyrosine residues in additional substrate polypeptides(s).

An "EGFR antagonist" (interchangeably termed "EGFR inhibitor") is an agent that interferes with EGFR activation or function. Examples of EGFR inhibitors include EGFR antibodies; EGFR ligand antibodies; small molecule EGFR antagonists; EGFR tyrosine kinase inhibitors; antisense and inhibitory RNA (e.g., shRNA) molecules (see, for example, WO2004/87207). Preferably, the EGFR inhibitor is an antibody or small molecule which binds to EGFR. In some embodiments, the EGFR inhibitor is an EGFR-targeted drug. In a particular embodiment, an EGFR inhibitor has a binding affinity (dissociation constant) to EGFR of about 1,000 nM or less. In another embodiment, an EGFR inhibitor has a binding affinity to EGFR of about 100 nM or less. In another embodiment, an EGFR inhibitor has a binding affinity to EGFR of about 50 nM or less. In a particular embodiment, an EGFR inhibitor is covalently bound to EGFR. In a particular embodiment, an EGFR inhibitor inhibits EGFR signaling with an IC50 of 1,000 nM or less. In another embodiment, an EGFR inhibitor inhibits EGFR signaling with an IC50 of 500 nM or less. In another embodiment, an EGFR inhibitor inhibits EGFR signaling with an IC50 of 50 nM or less.

The expressions "ErbB2" and "HER2" are used interchangeably herein and refer to human HER2 protein described, for example, in Semba et al, PNAS (USA) 82:6497-6501 (1985) and

"ErbB3" and "HER3" refer to the receptor polypeptide as disclosed, for example, in US Pat. Nos. 5,183,884 and 5,480,968 as well as Kraus et al PNAS (USA) 86:9193-9197 (1989).

As used herein, "ErbB" refers to the receptor polypeptides EGFR, HER2, HER3, and HER4.

"EGFR activation" refers to activation, or phosphorylation, of EGFR. Generally, EGFR activation results in signal transduction (e.g. that caused by an intracellular kinase domain of EGFR receptor phosphorylating tyrosine residues in EGFR or a substrate polypeptide). EGFR activation may be mediated by EGFR ligand binding to a EGFR dimer comprising EGFR. EGFR ligand binding to a EGFR dimer may activate a kinase domain of one or more of the EGFR in the dimer and thereby results in phosphorylation of tyrosine residues in one or more of the EGFR and/or phosphorylation of tyrosine residues in additional substrate polypeptides(s).

As used herein, the term "EGFR-targeted drug" refers to a therapeutic agent that binds to EGFR and inhibits EGFR activation. Examples of such agents include antibodies and small molecules that bind to EGFR. Examples of antibodies which bind to EGFR include MAb 579 (ATCC CRL HB 8506), MAb 455 (ATCC CRL HB8507), MAb 225 (ATCC CRL 8508), MAb 528 (ATCC CRL 8509) (see, US Patent No. 4,943, 533, Mendelsohn et al.) and variants thereof, such as chimerized 225 (C225 or Cetuximab; ERBUTIX®) and reshaped human 225 (H225) (see, WO 96/40210, Imclone Systems Inc.); IMC-1 1F8, a fully human, EGFR-targeted antibody (Imclone); antibodies that bind type II mutant EGFR (US Patent No. 5,212,290); humanized and chimeric antibodies that bind EGFR as described in US Patent No. 5,891,996; and human antibodies that bind EGFR, such as ABX-EGF (see WO98/50433, Abgenix); EMD 55900 (Stragiolitto et al Eur. J. Cancer 32A:636-640 (1996)); EMD7200 (matuzumab) a humanized EGFR antibody directed against EGFR that competes with both EGF and TGF-alpha for EGFR binding; and mAb 806 or humanized mAb 806 (Johns et al, J. Biol. Chem. 279(29):30375-30384 (2004)). The anti-EGFR antibody may be conjugated with a cytotoxic agent, thus generating an immunoconjugate (see, e.g., EP659,439A2, Merck Patent GmbH). Examples of small molecules that bind to EGFR include ZD1 839 or Gefitinib (IRESSA; Astra Zeneca); CP-358774 or Erlotinib (TARCEVA™; Genentech/OSI); and AG1478, AG1 571 (SU 5271; Sugen); and EMD-7200.

By "EGFR resistant" cancer is meant that the cancer patient has progressed while receiving an EGFR antagonist therapy (i.e., the patient is "EGFR refractory"), or the patient has progressed within 12 months (for instance, within one, two, three, or six months) after completing an EGFR antagonist-
based therapy regimen. For example, cancers which incorporate T790M mutant EGFR are resistant to erlotinib and gefitinib therapy.

By "erlotinib or gefitinib resistant" cancer is meant that the cancer patient has progressed while receiving erlotinib- or gefitinib-based therapy (i.e., the patient is "erlotinib or gefitinib refractory"), or the patient has progressed within 12 months (for instance, within one, two, three, or six months) after completing an erlotinib- or gefitinib-based therapy regimen.

The term "ligand-independent" as used herein, as for example applied to receptor signaling activity, refers to signaling activity that is not dependent on the presence of a ligand. For example, EGFR signaling may result from dimerization with other members of the HER family such as HER2. A receptor having ligand-independent kinase activity will not necessarily preclude the binding of ligand to that receptor to produce additional activation of the kinase activity.

The term "constitutive" as used herein, as for example applied to receptor kinase activity, refers to continuous signaling activity of a receptor that is not dependent on the presence of a ligand or other activating molecules. For example, EGFR variant III (EGFRvIII) which is commonly found in glioblastoma multiforme has deleted much of its extracellular domain. Although ligands are unable to bind EGFRvIII it is nevertheless continuously active and is associated with abnormal proliferation and survival. Depending on the nature of the receptor, all of the activity may be constitutive or the activity of the receptor may be further activated by the binding of other molecules (e.g., ligands). Cellular events that lead to activation of receptors are well known among those of ordinary skill in the art. For example, activation may include oligomerization, e.g., dimerization, trimerization, etc., into higher order receptor complexes. Complexes may comprise a single species of protein, i.e., a homomorphic complex. Alternatively, complexes may comprise at least two different protein species, i.e., a heteromeric complex. Complex formation may be caused by, for example, overexpression of normal or mutant forms of receptor on the surface of a cell. Complex formation may also be caused by a specific mutation or mutations in a receptor.

The phrase "gene amplification" refers to a process by which multiple copies of a gene or gene fragment are formed in a particular cell or cell line. The duplicated region (a stretch of amplified DNA) is often referred to as "amplicon." Usually, the amount of the messenger RNA (mRNA) produced, i.e., the level of gene expression, also increases in the proportion of the number of copies made of the particular gene expressed.

A "tyrosine kinase inhibitor" is a molecule which inhibits to some extent tyrosine kinase activity of a tyrosine kinase such as a c-met receptor.

A cancer or biological sample which "displays c-met and/or EGFR expression, amplification, or activation" is one which, in a diagnostic test, expresses (including overexpresses) c-met and/or EGFR, has amplified c-met and/or EGFR gene, and/or otherwise demonstrates activation or phosphorylation of a c-met and/or EGFR.
A cancer or biological sample which "does not display c-met and/or EGFR expression, amplification, or activation" is one which, in a diagnostic test, does not express (including overexpress) c-met and/or EGFR, does not have amplified c-met and/or EGFR gene, and/or otherwise does not demonstrate activation or phosphorylation of a c-met and/or EGFR.

A cancer or biological sample which "displays c-met and/or EGFR activation" is one which, in a diagnostic test, demonstrates activation or phosphorylation of c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A cancer or biological sample which "does not display c-met and/or EGFR activation" is one which, in a diagnostic test, does not demonstrate activation or phosphorylation of a c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A cancer or biological sample which "displays constitutive c-met and/or EGFR activation" is one which, in a diagnostic test, demonstrates constitutive activation or phosphorylation of a c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A cancer or biological sample which "does not display c-met and/or EGFR amplification" is one which, in a diagnostic test, does not have amplified c-met and/or EGFR gene.

A cancer or biological sample which "displays c-met and/or EGFR amplification" is one which, in a diagnostic test, has amplified c-met and/or EGFR gene.

A cancer or biological sample which "does not display constitutive c-met and/or EGFR activation" is one which, in a diagnostic test, does not demonstrate constitutive activation or phosphorylation of a c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A cancer or biological sample which "displays ligand-independent c-met and/or EGFR activation" is one which, in a diagnostic test, demonstrates ligand-independent activation or phosphorylation of a c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A cancer or biological sample which "does not display ligand-independent c-met and/or EGFR activation" is one which, in a diagnostic test, demonstrates ligand-independent activation or phosphorylation of a c-met and/or EGFR. Such activation can be determined directly (e.g. by measuring c-met and/or EGFR phosphorylation by ELISA) or indirectly.

A "phospho-ELISA assay" herein is an assay in which phosphorylation of one or more c-met and/or EGFR is evaluated in an enzyme-linked immunosorbent assay (ELISA) using a reagent, usually an antibody, to detect phosphorylated c-met and/or EGFR, substrate, or downstream signaling molecule. Preferably, an antibody which detects phosphorylated c-met and/or EGFR is used. The assay may be performed on cell lysates, preferably from fresh or frozen biological samples.
A cancer cell with "c-met and/or EGFR overexpression or amplification" is one which has significantly higher levels of a c-met and/or EGFR protein or gene compared to a noncancerous cell of the same tissue type. Such overexpression may be caused by gene amplification or by increased transcription or translation. c-met and/or EGFR overexpression or amplification may be determined in a diagnostic or prognostic assay by evaluating increased levels of the c-met and/or EGFR protein present on the surface of a cell (e.g. via an immunohistochemistry assay; IHC). Alternatively, or additionally, one may measure levels of c-met and/or EGFR -encoding nucleic acid in the cell, e.g. via fluorescent in situ hybridization (FISH; see WO98/45479 published October, 1998), southern blotting, or polymerase chain reaction (PCR) techniques, such as quantitative real time PCR (qRT-PCR). Aside from the above assays, various in vivo assays are available to the skilled practitioner. For example, one may expose cells within the body of the patient to an antibody which is optionally labeled with a detectable label, e.g. a radioactive isotope, and binding of the antibody to cells in the patient can be evaluated, e.g. by external scanning for radioactivity or by analyzing a biopsy taken from a patient previously exposed to the antibody.

A cancer cell which "does not overexpress or amplify c-met and/or EGFR" is one which does not have higher than normal levels of c-met and/or EGFR protein or gene compared to a noncancerous cell of the same tissue type.

The term "mutation", as used herein, means a difference in the amino acid or nucleic acid sequence of a particular protein or nucleic acid (gene, RNA) relative to the wild-type protein or nucleic acid, respectively. A mutated protein or nucleic acid can be expressed from or found on one allele (heterozygous) or both alleles (homozygous) of a gene, and may be somatic or germ line. In the instant invention, mutations are generally somatic. Mutations include sequence rearrangements such as insertions, deletions, and point mutations (including single nucleotide/mino acid polymorphisms).

To "inhibit" is to decrease or reduce an activity, function, and/or amount as compared to a reference.

Protein "expression" refers to conversion of the information encoded in a gene into messenger RNA (mRNA) and then to the protein.

Herein, a sample or cell that "expresses" a protein of interest (such as a HER receptor or HER ligand) is one in which mRNA encoding the protein, or the protein, including fragments thereof, is determined to be present in the sample or cell.

An " immunoconjugate" (interchangeably referred to as "antibody-drug conjugate," or "ADC") means an antibody conjugated to one or more cytotoxic agents, such as a chemotherapeutic agent, a drug, a growth inhibitory agent, a toxin (e.g., a protein toxin, an enzymatically active toxin of bacterial, fungal, plant, or animal origin, or fragments thereof), or a radioactive isotope (i.e., a radioconjugate).

The term "Fc region", as used herein, generally refers to a dimer complex comprising the C-terminal polypeptide sequences of an immunoglobulin heavy chain, wherein a C-terminal polypeptide
sequence is that which is obtainable by papain digestion of an intact antibody. The Fc region may
comprise native or variant Fc sequences. Although the boundaries of the Fc sequence of an
immunoglobulin heavy chain might vary, the human IgG heavy chain Fc sequence is usually defined
to stretch from an amino acid residue at about position Cys226, or from about position Pro230, to the
carboxyl terminus of the Fc sequence. The Fc sequence of an immunoglobulin generally comprises
two constant domains, a CH2 domain and a CH3 domain, and optionally comprises a CH4 domain.
The C-terminal lysine (residue 447 according to the EU numbering system) of the Fc region may be
removed, for example, during purification of the antibody or by recombinant engineering of the
nucleic acid encoding the antibody. Accordingly, a composition comprising an antibody having an Fc
region according to this invention can comprise an antibody with K447, with all K447 removed, or a
mixture of antibodies with and without the K447 residue.

By "Fc polypeptide" herein is meant one of the polypeptides that make up an Fc region. An
Fc polypeptide may be obtained from any suitable immunoglobulin, such as IgG, IgG2, IgG3, or IgG4
subtypes, IgA, IgE, IgD or IgM. In some embodiments, an Fc polypeptide comprises part or all of a
wild type hinge sequence (generally at its N terminus). In some embodiments, an Fc polypeptide does
not comprise a functional or wild type hinge sequence.

The "hinge region," "hinge sequence", and variations thereof, as used herein, includes the
meaning known in the art, which is illustrated in, for example, Janeway et al., Immuno Biology: the
immune system in health and disease, (Elsevier Science Ltd., NY) (4th ed., 1999); Bloom et al.,

Throughout the present specification and claims, the numbering of the residues in an
immunoglobulin heavy chain is that of the EU index as in Kabat et al., Sequences of Proteins of
Immunological Interest, 5th Ed. Public Health Service, National Institutes of Health, Bethesda, Md.
(1991), expressly incorporated herein by reference. The "EU index as in Kabat" refers to the residue
numbering of the human IgGl EU antibody.

The term "antibody" is used in the broadest sense and specifically covers monoclonal
antibodies (including full length monoclonal antibodies), polyclonal antibodies, multispecific
antibodies (e.g., bispecific antibodies), monovalent antibodies, multivalent antibodies, and antibody
fragments so long as they exhibit the desired biological activity.

"Antibody fragments" comprise only a portion of an intact antibody, wherein the portion
preferably retains at least one, preferably most or all, of the functions normally associated with that
portion when present in an intact antibody. In one embodiment, an antibody fragment comprises an
antigen binding site of the intact antibody and thus retains the ability to bind antigen. In another
embodiment, an antibody fragment, for example one that comprises the Fc region, retains at least one
of the biological functions normally associated with the Fc region when present in an intact antibody,
such as FcRn binding, antibody half life modulation, ADCC function and complement binding. In
one embodiment, an antibody fragment is a monovalent antibody that has an in vivo half life
substantially similar to an intact antibody. For example, such an antibody fragment may comprise on
antigen binding arm linked to an Fc sequence capable of conferring in vivo stability to the fragment.
In one embodiment, an antibody of the invention is a one-armed antibody as described in
WO2005/063816. In one embodiment, the one-armed antibody comprises Fc mutations constituting
"knobs" and "holes" as described in WO2005/063816. For example, a hole mutation can be one or
more of T366A, L368A and/or Y407V in an Fc polypeptide, and a cavity mutation can be T366W.

A "blocking" antibody or an antibody "antagonist" is one which inhibits or reduces biological
activity of the antigen it binds. Preferred blocking antibodies or antagonist antibodies completely
inhibit the biological activity of the antigen.

Unless indicated otherwise, the expression "multivalent antibody" is used throughout this
specification to denote an antibody comprising three or more antigen binding sites. The multivalent
antibody is preferably engineered to have the three or more antigen binding sites and is generally not a
native sequence IgM or IgA antibody.

An "Fv" fragment is an antibody fragment which contains a complete antigen recognition and
binding site. This region consists of a dimer of one heavy and one light chain variable domain in tight
association, which can be covalent in nature, for example in scFv. It is in this configuration that the
three CDRs of each variable domain interact to define an antigen binding site on the surface of the
V_{H}V_{L} dimer. Collectively, the six CDRs or a subset thereof confer antigen binding specificity to the
antibody. However, even a single variable domain (or half of an Fv comprising only three CDRs
specific for an antigen) has the ability to recognize and bind antigen, although usually at a lower
affinity than the entire binding site.

As used herein, "antibody variable domain" refers to the portions of the light and heavy
chains of antibody molecules that include amino acid sequences of Complementarity Determining
Regions (CDRs; i.e., CDR1, CDR2, and CDR3), and Framework Regions (FRs). V_{H} refers to the
variable domain of the heavy chain. V_{L} refers to the variable domain of the light chain. According to
the methods used in this invention, the amino acid positions assigned to CDRs and FRs may be
defined according to Kabat (Sequences of Proteins of Immunological Interest (National Institutes of
Health, Bethesda, Md., 1987 and 1991)). Amino acid numbering of antibodies or antigen binding
fragments is also according to that of Kabat.

As used herein, the term "Complementarity Determining Regions" (CDRs; i.e., CDR1,
CDR2, and CDR3) refers to the amino acid residues of an antibody variable domain the presence of
which are necessary for antigen binding. Each variable domain typically has three CDR regions
identified as CDR1, CDR2 and CDR3. Each complementarity determining region may comprise
amino acid residues from a "complementarity determining region" as defined by Kabat (i.e. about
residues 24-34 (L1), 50-56 (L2) and 89-97 (L3) in the light chain variable domain and 31-35 (H1), 50-
65 (H2) and 95-102 (H3) in the heavy chain variable domain; Kabat et al., Sequences of Proteins of
Immunological Interest, 5th Ed. Public Health Service, National Institutes of Health, Bethesda, MD.
(1991)) and/or those residues from a "hypervariable loop" (i.e. about residues 26-32 (L1), 50-52 (L2) and 91-96 (L3) in the light chain variable domain and 26-32 (H1), 53-55 (H2) and 96-101 (H3) in the heavy chain variable domain; Chothia and LeskJ. Mol. Biol. 196:901-917 (1987)). In some instances, a complementarity determining region can include amino acids from both a CDR region defined according to Kabat and a hypervariable loop. For example, the CDRH1 of the heavy chain of antibody 4D5 includes amino acids 26 to 35.

"Framework regions" (hereinafter FR) are those variable domain residues other than the CDR residues. Each variable domain typically has four FRs identified as FR1, FR2, FR3 and FR4. If the CDRs are defined according to Kabat, the light chain FR residues are positioned at about residues 1-23 (LCFR1), 35-49 (LCFR2), 57-88 (LCFR3), and 98-107 (LCFR4) and the heavy chain FR residues are positioned about at residues 1-30 (HCFR1), 36-49 (HCFR2), 66-94 (HCFR3), and 103-113 (HCFR4) in the heavy chain residues. If the CDRs comprise amino acid residues from hypervariable loops, the light chain FR residues are positioned about at residues 1-25 (LCFR1), 33-49 (LCFR2), 53-90 (LCFR3), and 97-107 (LCFR4) in the light chain and the heavy chain FR residues are positioned about at residues 1-25 (HCFR1), 33-52 (HCFR2), 56-95 (HCFR3), and 102-113 (HCFR4) in the heavy chain residues. In some instances, when the CDR comprises amino acids from both a CDR as defined by Kabat and those of a hypervariable loop, the FR residues will be adjusted accordingly. For example, when CDRH1 includes amino acids H26-H35, the heavy chain FR1 residues are at positions 1-25 and the FR2 residues are at positions 36-49.

The "Fab" fragment contains a variable and constant domain of the light chain and a variable domain and the first constant domain (CH1) of the heavy chain. F(ab')2 antibody fragments comprise a pair of Fab fragments which are generally covalently linked near their carboxy termini by hinge cysteines between them. Other chemical couplings of antibody fragments are also known in the art.

"Single-chain Fv" or "scFv" antibody fragments comprise the V_H and V_L domains of antibody, wherein these domains are present in a single polypeptide chain. Generally the Fv polypeptide further comprises a polypeptide linker between the V_H and V_L domains, which enables the scFv to form the desired structure for antigen binding. For a review of scFv, see Pluckthun in *The Pharmacology of Monoclonal Antibodies*, Vol 113, Rosenberg and Moore eds. Springer-Verlag, New York, pp. 269-315 (1994).

The term "diabodies" refers to small antibody fragments with two antigen-binding sites, which fragments comprise a heavy chain variable domain (V_H) connected to a light chain variable domain (V_L) in the same polypeptide chain (V_H and V_L). By using a linker that is too short to allow pairing between the two domains on the same chain, the domains are forced to pair with the complementary domains of another chain and create two antigen-binding sites. Diabodies are described more fully in, for example, EP 404,097; WO 93/11161; and Hollinger et al., *Proc. Natl. Acad. Sci. USA*, 90:6444-6448 (1993).

The expression "linear antibodies" refers to the antibodies described in Zapata et al., *Protein
Eng., 8(10):1057-1062 (1995). Briefly, these antibodies comprise a pair of tandem Fd segments (VH-CH1-VH-CH1) which, together with complementary light chain polypeptides, form a pair of antigen binding regions. Linear antibodies can be bispecific or monospecific.

The monoclonal antibodies herein specifically include "chimeric" antibodies in which a portion of the heavy and/or light chain is identical with or homologous to corresponding sequences in antibodies derived from a particular species or belonging to a particular antibody class or subclass, while the remainder of the chain(s) is identical with or homologous to corresponding sequences in antibodies derived from another species or belonging to another antibody class or subclass, as well as fragments of such antibodies, so long as they exhibit the desired biological activity (see, e.g., U.S. Patent No. 4,816,567; and Morrison et al, Proc. Natl. Acad. ScL USA 81:6851-6855 (1984)). Chimeric antibodies include PRIMATIZED® antibodies wherein the antigen-binding region of the antibody is derived from an antibody produced by, e.g., immunizing macaque monkeys with the antigen of interest.

"Humanized" forms of non-human (e.g., murine) antibodies are chimeric antibodies which contain minimal sequence derived from non-human immunoglobulin. For the most part, humanized antibodies are human immunoglobulins (recipient antibody) in which residues from a hypervariable
region of the recipient are replaced by residues from a hypervariable region of a non-human species (donor antibody) such as mouse, rat, rabbit or nonhuman primate having the desired specificity, affinity, and capacity. In some instances, Fv framework region (FR) residues of the human immunoglobulin are replaced by corresponding non-human residues. Furthermore, humanized antibodies may comprise residues which are not found in the recipient antibody or in the donor antibody. These modifications are made to further refine antibody performance. In general, the humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the hypervariable loops correspond to those of a non-human immunoglobulin and all or substantially all of the FR regions are those of a human immunoglobulin sequence. The humanized antibody optionally also will comprise at least a portion of an immunoglobulin constant region (Fc), typically that of a human immunoglobulin. For further details, see Jones et al., Nature 321:522-525 (1986); Riechmann et al., Nature 332:323-329 (1988); and Presta, Curr. Op. Struct. Biol. 2:593-596 (1992).

A "human antibody" is one which possesses an amino acid sequence which corresponds to that of an antibody produced by a human and/or has been made using any of the techniques for making human antibodies as disclosed herein. This definition of a human antibody specifically excludes a humanized antibody comprising non-human antigen-binding residues. Human antibodies can be produced using various techniques known in the art. In one embodiment, the human antibody is selected from a phage library, where that phage library expresses human antibodies (Vaughan et al. Nature Biotechnology 14:309-314 (1996): Sheets et al. Proc. Natl. Acad. Sci. 95:6157-6162 (1998)); Hoogenboom and Winter, J. Mol. Biol. 227:381 (1991); Marks et al., J. Mol. Biol. 222:581 (1991)). Human antibodies can also be made by introducing human immunoglobulin loci into transgenic animals, e.g., mice in which the endogenous immunoglobulin genes have been partially or completely inactivated. Upon challenge, human antibody production is observed, which closely resembles that seen in humans in all respects, including gene rearrangement, assembly, and antibody repertoire. This approach is described, for example, in U.S. Pat. Nos. 5,545,807; 5,545,806; 5,569,825; 5,625,126; 5,633,425; 5,661,016, and in the following scientific publications: Marks et al., Bio/Technology 10: 779-783 (1992); Lonberg et al., Nature 368: 856-859 (1994); Morrison, Nature 368:812-13 (1994); Fishwild et al., Nature Biotechnology 14: 845-51 (1996); Neuberger, Nature Biotechnology 14: 826 (1996); Lonberg and Huszar, Intern. Rev. Immunol. 13:65-93 (1995). Alternatively, the human antibody may be prepared via immortalization of human B lymphocytes producing an antibody directed against a target antigen (such B lymphocytes may be recovered from an individual or may have been immunized in vitro). See, e.g., Cole et al., Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, p. 77 (1985); Boerner et al., J. Immunol, 147 (l):86-95 (1991); and U.S. Pat. No. 5,750,373.

A "naked antibody" is an antibody that is not conjugated to a heterologous molecule, such as a cytotoxic moiety or radiolabel.

An antibody having a "biological characteristic" of a designated antibody is one which possesses one or more of the biological characteristics of that antibody which distinguish it from other antibodies that bind to the same antigen.

In order to screen for antibodies which bind to an epitope on an antigen bound by an antibody of interest, a routine cross-blocking assay such as that described in Antibodies, A Laboratory Manual, Cold Spring Harbor Laboratory, Ed Harlow and David Lane (1988), can be performed.

To increase the half-life of the antibodies or polypeptide containing the amino acid sequences of this invention, one can attach a salvage receptor binding epitope to the antibody (especially an antibody fragment), as described, e.g., in US Patent 5,739,277. For example, a nucleic acid molecule encoding the salvage receptor binding epitope can be linked in frame to a nucleic acid encoding a polypeptide sequence of this invention so that the fusion protein expressed by the engineered nucleic acid molecule comprises the salvage receptor binding epitope and a polypeptide sequence of this invention. As used herein, the term "salvage receptor binding epitope" refers to an epitope of the Fc region of an IgG molecule (e.g., IgG1, IgG2, IgG3, or IgG4) that is responsible for increasing the in vivo serum half-life of the IgG molecule (e.g., Ghetie et al., Ann. Rev. Immunol. 18:739-766 (2000), Table 1). Antibodies with substitutions in an Fc region thereof and increased serum half-lives are also described in WO00/42072, WO 02/060919; Shields et al., J. Biol. Chem. 276:6591-6604 (2001); Hinton, J. Biol. Chem. 279:6213-6216 (2004)). In another embodiment, the serum half-life can also be increased, for example, by attaching other polypeptide sequences. For example, antibodies or other polypeptides useful in the methods of the invention can be attached to serum albumin or a portion of serum albumin that binds to the FcRn receptor or a serum albumin binding peptide so that serum albumin binds to the antibody or polypeptide, e.g., such polypeptide sequences are disclosed in WO01/45746. In one preferred embodiment, the serum albumin peptide to be attached comprises an amino acid sequence of DICLPRWGCLW (SEQ ID NO:21). In another embodiment, the half-life of a Fab is increased by these methods. See also, Dennis et al. J. Biol. Chem. 277:35035-35043 (2002) for serum albumin binding peptide sequences.

An "isolated" polypeptide or "isolated" antibody is one that has been identified and separated and/or recovered from a component of its natural environment. Contaminant components of its
natural environment are materials that would interfere with diagnostic or therapeutic uses for the polypeptide or antibody, and may include enzymes, hormones, and other proteinaceous or nonproteinaceous solutes. In preferred embodiments, the polypeptide or antibody will be purified (1) to greater than 95% by weight of polypeptide or antibody as determined by the Lowry method, and most preferably more than 99% by weight, (2) to a degree sufficient to obtain at least 15 residues of N-terminal or internal amino acid sequence by use of a spinning cup sequenator, or (3) to homogeneity by SDS-PAGE under reducing or nonreducing conditions using Coomassie blue or, preferably, silver stain. Isolated polypeptide or antibody includes the polypeptide or antibody in situ within recombinant cells since at least one component of the polypeptide's natural environment will not be present.Ordinarily, however, isolated polypeptide or antibody will be prepared by at least one purification step.

By "fragment" is meant a portion of a polypeptide or nucleic acid molecule that contains, preferably, at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, or more of the entire length of the reference nucleic acid molecule or polypeptide. A fragment may contain 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100, 200, 300, 400, 500, 600, or more nucleotides or 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 140, 160, 180, 190, 200 amino acids or more.

"Treatment" refers to both therapeutic treatment and prophylactic or preventative measures. Those in need of treatment include those already having a benign, pre-cancerous, or non-metastatic tumor as well as those in which the occurrence or recurrence of cancer is to be prevented.

The term "therapeutically effective amount" refers to an amount of a therapeutic agent to treat or prevent a disease or disorder in a mammal. In the case of cancers, the therapeutically effective amount of the therapeutic agent may reduce the number of cancer cells; reduce the primary tumor size; inhibit (i.e., slow to some extent and preferably stop) cancer cell infiltration into peripheral organs; inhibit (i.e., slow to some extent and preferably stop) tumor metastasis; inhibit, to some extent, tumor growth; and/or relieve to some extent one or more of the symptoms associated with the disorder. To the extent the drug may prevent growth and/or kill existing cancer cells, it may be cytostatic and/or cytotoxic. For cancer therapy, efficacy in vivo can, for example, be measured by assessing the duration of survival, time to disease progression (TTP), the response rates (RR), duration of response, and/or quality of life.

The terms "cancer" and "cancerous" refer to or describe the physiological condition in mammals that is typically characterized by unregulated cell growth. Included in this definition are benign and malignant cancers. By "early stage cancer" or "early stage tumor" is meant a cancer that is not invasive or metastatic or is classified as a Stage 0, I, or II cancer. Examples of cancer include, but are not limited to, carcinoma, lymphoma, blastoma (including medulloblastoma and retinoblastoma), sarcoma (including liposarcoma and synovial cell sarcoma), neuroendocrine tumors (including carcinoid tumors, gastrinoma, and islet cell cancer), mesothelioma, schwannoma (including acoustic neuroma), meningioma, adenocarcinoma, melanoma, and leukemia or lymphoid
malignancies. More particular examples of such cancers include squamous cell cancer (e.g. epithelial squamous cell cancer), lung cancer including small-cell lung cancer (SCLC), non-small cell lung cancer (NSCLC), adenocarcinoma of the lung and squamous carcinoma of the lung, cancer of the peritoneum, hepatocellular cancer, gastric or stomach cancer including gastrointestinal cancer, pancreatic cancer, glioblastoma, cervical cancer, ovarian cancer, liver cancer, bladder cancer, hepatoma, breast cancer (including metastatic breast cancer), colon cancer, rectal cancer, colorectal cancer, endometrial or uterine carcinoma, salivary gland carcinoma, kidney or renal cancer, prostate cancer, vulval cancer, thyroid cancer, hepatic carcinoma, anal carcinoma, penile carcinoma, testicular cancer, esophageal cancer, tumors of the biliary tract, as well as head and neck cancer.

The term "pre-cancerous" refers to a condition or a growth that typically precedes or develops into a cancer. A "pre-cancerous" growth will have cells that are characterized by abnormal cell cycle regulation, proliferation, or differentiation, which can be determined by markers of cell cycle regulation, cellular proliferation, or differentiation.

By "dysplasia" is meant any abnormal growth or development of tissue, organ, or cells. Preferably, the dysplasia is high grade or precancerous.

By "metastasis" is meant the spread of cancer from its primary site to other places in the body. Cancer cells can break away from a primary tumor, penetrate into lymphatic and blood vessels, circulate through the bloodstream, and grow in a distant focus (metastasize) in normal tissues elsewhere in the body. Metastasis can be local or distant. Metastasis is a sequential process, contingent on tumor cells breaking off from the primary tumor, traveling through the bloodstream, and stopping at a distant site. At the new site, the cells establish a blood supply and can grow to form a life-threatening mass.

Both stimulatory and inhibitory molecular pathways within the tumor cell regulate this behavior, and interactions between the tumor cell and host cells in the distant site are also significant.

By "non-metastatic" is meant a cancer that is benign or that remains at the primary site and has not penetrated into the lymphatic or blood vessel system or to tissues other than the primary site. Generally, a non-metastatic cancer is any cancer that is a Stage 0, I, or II cancer, and occasionally a Stage III cancer.

By "primary tumor" or "primary cancer" is meant the original cancer and not a metastatic lesion located in another tissue, organ, or location in the subject's body.

By "benign tumor" or "benign cancer" is meant a tumor that remains localized at the site of origin and does not have the capacity to infiltrate, invade, or metastasize to a distant site.

By "tumor burden" is meant the number of cancer cells, the size of a tumor, or the amount of cancer in the body. Tumor burden is also referred to as tumor load.

By "tumor number" is meant the number of tumors.

By "subject" is meant a mammal, including, but not limited to, a human or non-human mammal, such as a bovine, equine, canine, ovine, or feline. Preferably, the subject is a human.
The term "anti-cancer therapy" refers to a therapy useful in treating cancer. Examples of anti-cancer therapeutic agents include, but are limited to, e.g., chemotherapeutic agents, growth inhibitory agents, cytotoxic agents, agents used in radiation therapy, anti-angiogenesis agents, apoptotic agents, anti-tubulin agents, and other agents to treat cancer, anti-CD20 antibodies, platelet derived growth factor inhibitors (e.g., Gleevec™ (Imatinib Mesylate)), a COX-2 inhibitor (e.g., celecoxib), interferons, cytokines, antagonists (e.g., neutralizing antibodies) that bind to one or more of the following targets ErbB2, ErbB3, ErbB4, PDGFR-beta, BlyS, APRIL, BCMA or VEGF receptor(s), TRAIL/Apo2, and other bioactive and organic chemical agents, etc. Combinations thereof are also included in the invention.

The term "cytotoxic agent" as used herein refers to a substance that inhibits or prevents the function of cells and/or causes destruction of cells. The term is intended to include radioactive isotopes (e.g., I¹³¹, I¹²⁵, Y⁹⁰ and Re¹⁸⁶), chemotherapeutic agents, and toxins such as enzymatically active toxins of bacterial, fungal, plant or animal origin, or fragments thereof.

A "chemotherapeutic agent" is a chemical compound useful in the treatment of cancer. Examples of chemotherapeutic agents include is a chemical compound useful in the treatment of cancer. Examples of chemotherapeutic agents include alkylating agents such as thiotepa and CYTOXAN® cyclophosphamide; alkyl sulfonates such as busulfan, imposulfan and piposulfan; aziridines such as benzodopa, carboquone, meturedopa, and uredopa; ethylenimines and methylamelamines including altretamine, triethylenemelamine, trietylenephosphoramide, triethylenethiophosphoramide and trimethylolelamine; acetylenicis (especially bullatacin and bullatacinone); a camptothecin (including the synthetic analogue topotecan); bryostatin; calydictin; CC-1065 (including its adozelesin, carzelesin and bizelesin synthetic analogues); cryptophycins (particularly cryptophycin 1 and cryptophycin 8); dolastatin; duocarmycin (including the synthetic analogues, KW-2189 and CBI-TM1); eleutherobin; pancratistatin; a sarcodictyin; spongistatin; nitrogen mustards such as chlorambucil, chloraphazine, chlorophosphamide, estramustine, ifosfamide, mechloretamine, mechloretamine oxide hydrochloride, melphalan, novembichin, phenesterine, prednimustine, trofosfamide, uracil mustard; nitrosureas such as carmustine, chlorozotocin, fotemustine, lomustine, nimustine, and ranimustine; antibiotics such as the enediyne antibiotics (e.g., calicheamicin, especially calicheamicin gammall and calicheamicin omegall (see, e.g., Agnew, *Chem Intnl. Ed. Engl.*, 33: 183-186 (1994)); dynemicin, including dynemicin A; bisphosphonates, such as clodronate; an esperamicin; as well as neocarzinostatin chromophore and related chromoprotein enediyne antiobiotic chromophores), aclacinomysins, actinomycin, authramycin, azaserine, bleomycins, cactinomycin, carabycin, carminomycin, carzinophilin, chromomycins, dactinomycin, daunorubicin, detorubicin, 6-diazo-5-oxo-L-norleucine, ADRIAMYCIN® doxorubicin (including morpholino-doxorubicin, cyanomorpholino-doxorubicin, 2-pyrrolino-doxorubicin and deoxydoxorubicin, epirubicin, esorubicin, idarubicin, marcellomycin, mitomycins such as mitomycin C, mycophenolic acid, nogalamycin, olivomycins, peplomycin,
potfiromycin, puromycin, quelamycin, rodorubicin, streptonigrin, streptozocin, tubercidin, ubenimex, zinostatin, zorubicin; anti-metabolites such as methotrexate and 5-fluourouracil (5-FU); folic acid analogues such as denopterin, methotrexate, pteropterin, trimetrexate; purine analogs such as fludarabine, 6-mercaptopurine, thiamiprine, thioguanine; pyrimidine analogs such as ancitabine, azacitidine, 6-azauridine, carmofur, cytarabine, dideoxyuridine, doxifluridine, enocitabine, floxuridine; androgens such as calusterone, dromostanolone propionate, epitiostanol, meptiostane, testolactone; anti-adrenals such as aminoglutethimide, mitotane, trilostane; folic acid replenisher such as folinic acid; acetate; aminopterin; aminolevulinic acid; pirarubicin; podophyllinic acid; 2-ethylhydrazide; procarbazine; PSK® polysaccharide complex (JHS Natural Products, Eugene, OR); razoxane; rhizoxin; sizofiran; spirogermanium; tenuazonic acid; triaziquone; 2,2’,2”-trichlorotriethylamine; trichothecenes (especially T-2 toxin, verracurin A, roridin A and anguidine); urethan; vindesine; dacarbazine; mannomustine; mitobronitol; mitolactol; pipobroman; gacytosine; arabinoside ("Ara-C"); cyclophosphamide; thiota; taxoids, e.g., TAXOL® paclitaxel (Bristol-Myers Squibb Oncology, Princeton, NJ.), ABRAXANE™ Cremophor-free, albumin-engineered nanoparticle formulation of paclitaxel (American Pharmaceutical Partners, Schaumberg, Illinois), and TAXOTERE® doxetaxel (Rhone-Poulenc Rorer, Antony, France); chloranbucil; GEMZAR® gemcitabine; 6-thioguanine; mercaptopurine; methotrexate; platinum analogs such as cisplatin and carboplatin; vinblastine; platinum; etoposide (VP-1 6); ifosfamide; mitoxantrone; vincristine; NAELBINE® vinorelbine; novantrone; teniposide; edatrexate; daunomycin; aminopterin; xeloda; ibandronate; irinotecan (Camptosar, CPT-11) (including the treatment regimen of irinotecan with 5-FU and leucovorin); topoisomerase inhibitor RFS 2000; difluoromethylornithine (DMFO); retinoids such as retinoic acid; capecitabine; combretastatin; leucovorin (LV); oxaliplatin, including the oxaliplatin treatment regimen (FOLFOX); inhibitors of PKC-alpha, Raf, H-Ras, EGFR (e.g., erlotinib (Tarceva™)) and VEGF-A that reduce cell proliferation and pharmaceutically acceptable salts, acids or derivatives of any of the above.

Also included in this definition are anti-hormonal agents that act to regulate or inhibit hormone action on tumors such as anti-estrogens and selective estrogen receptor modulators (SERMs), including, for example, tamoxifen (including NOLVADEX® tamoxifen), raloxifene, droloxifene, 4-hydroxytamoxifen, trioxifene, keoxifene, LY1 17018, onapristone, and FARESTON-toremifene; aromatase inhibitors that inhibit the enzyme aromatase, which regulates estrogen production in the adrenal glands, such as, for example, 4(5)-imidazoles, aminoglutethimide, MEGASE® megestrol acetate, AROMASIN® exemestane, formestane, fadrozole, RJVISOR® vorozole, FEMARA® letrozole, and ARIMIDEX® anastrozole; and anti-androgens such as
flutamide, nilutamide, bicalutamide, leuprolide, and goserelin; as well as troxacitabine (a 1,3-dioxolane nucleoside cytosine analog); antisense oligonucleotides, particularly those which inhibit expression of genes in signaling pathways implicated in abberant cell proliferation, such as, for example, PKC-alpha, Raf and H-Ras; ribozymes such as a VEGF expression inhibitor (e.g., ANGIOZYME® ribozyme) and a HER2 expression inhibitor; vaccines such as gene therapy vaccines, for example, ALLOVECTIN® vaccine, LEUVECTIN® vaccine, and VAXID® vaccine; PROLEUKIN® rIL-2; LURTOTECAN® topoisomerase 1 inhibitor; ABARELIX® rmRH; Vinorelbine and Esperamicins (see U.S. Pat. No. 4,675,187), and pharmaceutically acceptable salts, acids or derivatives of any of the above.

The term "prodrug" as used in this application refers to a precursor or derivative form of a pharmaceutically active substance that is less cytotoxic to tumor cells compared to the parent drug and is capable of being enzymatically activated or converted into the more active parent form. See, e.g., Wilman, "Prodrugs in Cancer Chemotherapy" Biochemical Society Transactions, 14, pp. 375-382, 615th Meeting Belfast (1986) and Stella et al., "Prodrugs: A Chemical Approach to Targeted Drug Delivery," Directed Drug Delivery, Borchardt et al., (ed.), pp. 247-267, Humana Press (1985). The prodrugs of this invention include, but are not limited to, phosphate-containing prodrugs, thiophosphate-containing prodrugs, sulfate-containing prodrugs, peptide-containing prodrugs, D-amino acid-modified prodrugs, glycosylated prodrugs, β-lactam-containing prodrugs, optionally substituted phenoxyacetamide-containing prodrugs or optionally substituted phenylacetamide-containing prodrugs, 5-fluorocytosine and other 5-fluorouridine prodrugs which can be converted into the more active cytotoxic free drug. Examples of cytotoxic drugs that can be derivatized into a prodrug form for use in this invention include, but are not limited to, those chemotherapeutic agents described above.

By "radiation therapy" is meant the use of directed gamma rays or beta rays to induce sufficient damage to a cell so as to limit its ability to function normally or to destroy the cell altogether. It will be appreciated that there will be many ways known in the art to determine the dosage and duration of treatment. Typical treatments are given as a one time administration and typical dosages range from 10 to 200 units (Grays) per day.

**Therapeutic agents**

The present invention features the use of c-met antagonists and EGFR antagonists in combination therapy to treat a pathological condition, such as tumor, in a subject.

**C-met antagonists**

C-met antagonists useful in the methods of the invention include polypeptides that specifically bind to c-met, anti-c-met antibodies, c-met small molecules, receptor molecules and derivatives which bind specifically to c-met, and fusions proteins. C-met antagonists also include antagonistic variants of c-met polypeptides, RNA aptamers and peptibodies against c-met and HGF. Also included as c-met antagonists useful in the methods of the invention are anti-HGF antibodies,
anti-HGF polypeptides, c-met receptor molecules and derivatives which bind specifically to HGF. Examples of each of these are described below.

Anti-c-met antibodies that are useful in the methods of the invention include any antibody that binds with sufficient affinity and specificity to c-met and can reduce or inhibit c-met activity. The antibody selected will normally have a sufficiently strong binding affinity for c-met, for example, the antibody may bind human c-met with a Kd value of between 100 nM-1 pM. Antibody affinities may be determined by a surface plasmon resonance based assay (such as the BIAcore assay as described in PCT Application Publication No. WO2005/0 12359); enzyme-linked immunoabsorbent assay (ELISA); and competition assays (e.g. RIA’s), for example. Preferably, the anti-c-met antibody of the invention can be used as a therapeutic agent in targeting and interfering with diseases or conditions wherein c-met/HGF activity is involved. Also, the antibody may be subjected to other biological activity assays, e.g., in order to evaluate its effectiveness as a therapeutic. Such assays are known in the art and depend on the target antigen and intended use for the antibody.

Anti-c-met antibodies are known in the art (see, e.g., Martens, T, et al (2006) Clin Cancer Res 12(20 Pt 1):6144; US 6,468,529; WO2006/015371; WO2007/063816; US7,408,043; WO2009/007427; WO2005/016382; WO2007/126799. In one embodiment, the anti-c-met antibody comprises a heavy chain variable domain comprising one or more of CDR1-HC, CDR2-HC and CDR3-HC sequence depicted in Figure 7 (SEQ ID NO: 13-15). In some embodiments, the antibody comprises a light chain variable domain comprising one or more of CDR1-LC, CDR2-LC and CDR3-LC sequence depicted in Figure 7 (SEQ ID NO: 5-7). In some embodiments, the heavy chain variable domain comprises FRI-HC, FR2-HC, FR3-HC and FR4-HC sequence depicted in Figure 7 (SEQ ID NO: 9-12). In some embodiments, the light chain variable domain comprises FRI-LC, FR2-LC, FR3-LC and FR4-LC sequence depicted in Figure 7 (SEQ ID NO: 1-4). In some embodiments, the anti-c-met antibody is monovalent and comprises an Fc region. In some embodiments, the antibody comprises Fc sequence depicted in Figure 7 (SEQ ID NO: 17).

In some embodiments, the antibody is monovalent and comprises a Fc region, wherein the Fc region comprises a first and a second polypeptide, wherein the first polypeptide comprises the Fc sequence depicted in Figure 7 (SEQ ID NO: 17) and the second polypeptide comprises the Fc sequence depicted in Figure 8 (SEQ ID NO: 18).

In one embodiment, the anti-c-met antibody comprises (a) a first polypeptide comprising a heavy chain variable domain having the sequence:

QVQLQSGPELVRPGASVKMSCRASYTFTSYWLHWVKQRPGQGLEWIGMIDPSNSDTRFN PNFKDKATLNVDRSSNTAYMLLSSLTSADSVYCATGYSVPSLDYWGQGTSVTVSS

(SEQ ID NO: 19), CHI sequence depicted in Figure 7 (SEQ ID NO: 16), and the Fc sequence depicted in Figure 7 (SEQ ID NO: 17); and (b) a second polypeptide comprising a light chain variable domain having the sequence:

DIMMSQPSLTVSVGKVTVSCKSSQSLYTYSSQKNLYAWQKPGQSPKLLYIYWASTRES
GVPDRFTGSGSGTDFTLTITSVKAD
dLAVYYCQQYYAYPWTFGGGTKLEIK (SEQ ID NO:20), and CLl sequence depicted in Figure 7 (SEQ ID NO: 8); and (c) a third polypeptide comprising the Fc sequence depicted in Figure 8 (SEQ ID NO: 18).

In other embodiments, the anti-c-met antibody is the monoclonal antibody produced by the hybridoma cell line deposited under American Type Culture Collection Accession Number ATCC HB-1 1894 (hybridoma 1A3.3.13) or HB-1 1895 (hybridoma 5D5.1.6). In other embodiments, the antibody comprises one or more of the CDR sequences of the monoclonal antibody produced by the hybridoma cell line deposited under American Type Culture Collection Accession Number ATCC HB-1 1894 (hybridoma 1A3.3.13) or HB-1 1895 (hybridoma 5D5.1.6).

In other embodiments, a c-met antibody of the invention specifically binds at least a portion of c-met Sema domain or variant thereof. In one example, an antagonist antibody of the invention specifically binds at least one of the sequences selected from the group consisting of LDAQT (SEQ ID NO:22) (e.g., residues 269-273 of c-met), LTEKRKKRS (SEQ ID NO:23) (e.g., residues 300-308 of c-met), KPDSAEMP (SEQ ID NO:24) (e.g., residues 350-357 of c-met) and NVRCLQHF (SEQ ID NO:25) (e.g., residues 381-388 of c-met). In one embodiment, an antagonist antibody of the invention specifically binds a conformational epitope formed by part or all of at least one of the sequences selected from the group consisting of LDAQT (SEQ ID NO:22) (e.g., residues 269-273 of c-met), LTEKRKKRS (SEQ ID NO:23) (e.g., residues 300-308 of c-met), KPDSAEMP (SEQ ID NO:24) (e.g., residues 350-357 of c-met) and NVRCLQHF (SEQ ID NO:25) (e.g., residues 381-388 of c-met). In one embodiment, an antagonist antibody of the invention specifically binds an amino acid sequence having at least 50%, 60%, 70%, 80%, 90%, 95%, 98% sequence identity or similarity with the sequence LDAQT (SEQ ID NO:22), LTEKRKKRS (SEQ ID NO:23), KPDSAEMP (SEQ ID NO:24) and/or NVRCLQHF (SEQ ID NO:25).

C-met receptor molecules or fragments thereof that specifically bind to HGF can be used in the methods of the invention, e.g., to bind to and sequester the HGF protein, thereby preventing it from signaling. Preferably, the c-met receptor molecule, or HGF binding fragment thereof, is a soluble form. In some embodiments, a soluble form of the receptor exerts an inhibitory effect on the biological activity of the c-met protein by binding to HGF, thereby preventing it from binding to its natural receptors present on the surface of target cells. Also included are c-met receptor fusion proteins, examples of which are described below.

A soluble c-met receptor protein or chimeric c-met receptor proteins of the present invention includes c-met receptor proteins which are not fixed to the surface of cells via a transmembrane domain. As such, soluble forms of the c-met receptor, including chimeric receptor proteins, while capable of binding to and inactivating HGF, do not comprise a transmembrane domain and thus
generally do not become associated with the cell membrane of cells in which the molecule is expressed. See, e.g., Kong-Beltran, M et al Cancer Cell (2004) 6(1): 75-84.

HGF molecules or fragments thereof that specifically bind to c-met and block or reduce activation of c-met, thereby preventing it from signaling, can be used in the methods of the invention.

Aptamers are nucleic acid molecules that form tertiary structures that specifically bind to a target molecule, such as a HGF polypeptide. The generation and therapeutic use of aptamers are well established in the art. See, e.g., U.S. Pat. No. 5,475,096. A HGF aptamer is a pegylated modified oligonucleotide, which adopts a three-dimensional conformation that enables it to bind to extracellular HGF. Additional information on aptamers can be found in U.S. Patent Application Publication No. 20060148748.

A peptibody is a peptide sequence linked to an amino acid sequence encoding a fragment or portion of an immunoglobulin molecule. Polypeptides may be derived from randomized sequences selected by any method for specific binding, including but not limited to, phage display technology. In a preferred embodiment, the selected polypeptide may be linked to an amino acid sequence encoding the Fc portion of an immunoglobulin. Peptibodies that specifically bind to and antagonize HGF or c-met are also useful in the methods of the invention.

EGFR antagonists

EGFR antagonists include antibodies such as humanized monoclonal antibody known as nimotuzumab (YM Biosciences), fully human ABX-EGF (panitumumab, Abgenix Inc.) as well as fully human antibodies known as El. 1, E2.4, E2.5, E6.2, E6.4, E2.1, E6.3 and E7.6. 3 and described in US 6,235,883; MDX-447 (Medarex Inc). Pertuzumab (2C4) is a humanized antibody that binds directly to HER2 but interferes with HER2-EGFR dimerization thereby inhibiting EGFR signaling. Other examples of antibodies which bind to EGFR include MAb 579 (ATCC CRL HB 8506), MAb 455 (ATCC CRL HB8507), MAb 225 (ATCC CRL 8508), MAb 528 (ATCC CRL 8509) (see, US Patent No. 4,943, 533, Mendelsohn et al.) and variants thereof, such as chimerized 225 (C225 or Cetuximab; ERBUTIX®) and reshaped human 225 (H225) (see, WO 96/04210, Imclone Systems Inc.); IMC-1 IF8, a fully human, EGFR-targeted antibody (Imclone); antibodies that bind type II
mutant EGFR (US Patent No. 5,212,290); humanized and chimeric antibodies that bind EGFR as described in US Patent No. 5,891,996; and human antibodies that bind EGFR, such as ABX-EGF (see WO98/50433, Abgenix); EMD 55900 (Stragliotto et al. Eur. J. Cancer 32A:636-640 (1996)); EMD7200 (matuzumab) a humanized EGFR antibody directed against EGFR that competes with both EGF and TGF-alpha for EGFR binding; and mAb 806 or humanized mAb 806 (Johns et al., J. Biol. Chem. 279(29):30375-30384 (2004)). The anti-EGFR antibody may be conjugated with a cytotoxic agent, thus generating an immunoconjugate (see, e.g., EP659,439A2, Merck Patent GmbH).

Anti-EGFR antibodies that are useful in the methods of the invention include any antibody that binds with sufficient affinity and specificity to EGFR and can reduce or inhibit EGFR activity. The antibody selected will normally have a sufficiently strong binding affinity for EGFR, for example, the antibody may bind human c-met with a Kd value of between 100 nM-1 pM. Antibody affinities may be determined by a surface plasmon resonance based assay (such as the BIAcore assay as described in PCT Application Publication No. WO2005/012359); enzyme-linked immunoabsorbent assay (ELISA); and competition assays (e.g. RIA’s), for example. Preferably, the anti-c-met antibody of the invention can be used as a therapeutic agent in targeting and interfering with diseases or conditions wherein EGFR/EGFR ligand activity is involved. Also, the antibody may be subjected to other biological activity assays, e.g., in order to evaluate its effectiveness as a therapeutic. Such assays are known in the art and depend on the target antigen and intended use for the antibody.

Bispecific antibodies are antibodies that have binding specificities for at least two different epitopes. Exemplary bispecific antibodies may bind to EGFR and to c-met. In another example, an exemplary bispecific antibody may bind to different epitopes of the same protein, e.g., c-met protein. Alternatively, a c-met or EGFR arm may be combined with an arm which binds to a triggering molecule on a leukocyte such as a T-cell receptor molecule (e.g. CD2 or CD3), or Fc receptors for IgG (FcγR), such as FcγRI (CD64), FcγRII (CD32) and FcγRIII (CD16) so as to focus cellular defense mechanisms to the c-met or EGFR-expressing cell. Bispecific antibodies may also be used to localize cytotoxic agents to cells which express EGFR or c-met. These antibodies possess a EGFR or c-met-binding arm and an arm which binds the cytotoxic agent (e.g. saporin, anti-interferon-α, vinca alkaloid, ricin A chain, methotrexate or radioactive isotope hapten). Bispecific antibodies can be prepared as full length antibodies or antibody fragments (e.g. F(ab’)2bispecific antibodies).

In a particular embodiment, the EGFR antagonist has a general formula I:

![Diagram](image)

in accordance with US 5,757,498, incorporated herein by reference, wherein:

m is 1, 2, or 3;

each R\(^1\) is independently selected from the group consisting of hydrogen, halo, hydroxy,
hydroxyamino, carboxy, nitro, guanidino, ureido, cyano, trifluoromethyl, and -(Ci -C\(_4\) alkylene)-W-
(phenyl) wherein W is a single bond, O, S or NH;

or each R\(^1\) is independently selected from R\(^9\) and Q-C\(_4\) alkyl substituted by cyano, wherein
R\(^9\) is selected from the group consisting of R\(^5\), -OR\(^5\), -NR\(^6\) R\(^6\), -C(O)R\(^7\), -NHOR\(^5\), -OC(O)R\(^6\), cyano,
A and -YR\(^5\); R\(^5\) is C\(_1\)-C\(_4\) alkyl; R\(^6\) is independently hydrogen or R\(^5\); R\(^7\) is R\(^5\), -OR\(^6\) or -NR\(^6\)R\(^6\); A is
selected from piperidino, morpholino, pyrrolidino, 4-R\(^6\)-piperazin-l-yl, imidazol-1-yl, 4-pyridon-1-yl,
-(Ci -C\(_4\) alkylene)(CO2H), phenoxy, phenyl, phenylsulfanyl, C\(_2\)-C\(_4\) alkenyl, and -(Ci-C\(_4\)
alkylene)C(O)NR\(^6\)R\(^6\); and Y is S, SO, or SO\(_2\); wherein the alkyl moieties in R\(^5\), -OR\(^6\) and -NR\(^6\)R\(^6\) are
optionally substituted by one to three halo substituents and the alkyl moieties in R\(^5\), -OR\(^6\) and -NR\(^6\)R\(^6\)
are optionally substituted by 1 or 2 R\(^9\) groups, and wherein the alkyl moieties of said optional
substituents are optionally substituted by halo or R\(^9\), with the proviso that two heteroatoms are not
attached to the same carbon atom;

or each R\(^1\) is independently selected from -NHSO\(_2\)R\(^5\), phthalimido-(Ci-C\(_4\))-
alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido, 2-oxopyrrolidin-l-yl, 2,5-
dioxopyrrolidin-l-yl, and R\(^R\)-[C\(_2\)-C\(_4\)]-alkanoylamino wherein R\(^R\) is selected from halo, -OR\(^6\), C\(_2\)-C\(_4\)

37
alkanoyloxy, -C(O)R, and -NR₆R; and wherein said -NHSO₂R, phthalimido-(C₆H₄)
alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido, 2-oxopyrrolidin-1-yl, 2,5-
dioxopyrrolidin-1-yl, and R⁽ⁿ⁾-(C₂₋₅)-alkanoylamino R¹ groups are optionally substituted by 1 or 2
substituents independently selected from halo, CpC₄ alkyl, cyano, methanesulfonyl and Ci-C₆ alkoxy;
or two R¹ groups are taken together with the carbons to which they are attached to form a 5-8
membered ring that includes 1 or 2 heteroatoms selected from O, S and N;
R² is hydrogen or Ci-C₆ alkyl optionally substituted by 1 to 3 substituents independently
selected from halo, Ci-C₄ alkoxy, -NR₆R, and -SO₂R;
R³ is hydrogen or halogen; and each R³ is independently selected from hydrogen, Ci-C₆ alkyl, -
NR₆R, and CpC₄ alkoxy, wherein the alkyl moieties of said R³ groups are optionally substituted by 1
to 3 substituents independently selected from halo, CpC₄ alkoxy, -NR₆R, and -SO₂R; and
R⁴ is azido or -(ethyl)-R⁵ wherein R⁵ is hydrogen or Ci-C₆ alkyl optionally substituted by
hydroxy, -OR, or -NR₆R.

In a particular embodiment, the EGFR antagonist is a compound according to formula I

selected from the group consisting of:
(6,7-dimethoxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-
[3-(3'-hydroxypropyn-1'-yl)phenyl]-amine; [3-(2'-aminomethyl)-ethylphenyl]- (6,7-
dimethoxyquinazolin-4-yl)-amine; (3-ethylphenyl)-(6-nitroquinazolin-4-yl)-amine; (6,7-
dimethoxyquinazolin-4-yl)-(4-ethylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethyl-2-
 methylphenyl)-amine; (6-aminoquinazolin-4-yl)-(3-ethylphenyl)-amine; (3-ethylphenyl)-(6-
methanesulfonylaminquinazolin-4-yl)-amine; (3-ethylphenyl)-(6-methylenedioxyquinazolin-4-
yl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethyl-6-methylphenyl)-amine; (3-ethylphenyl)-
(7-nitroquinazolin-4-yl)-amine; (3-ethylphenyl)-(6-[4'-toluenesulfonylaminquinazolin-4-yl]-
amine; (3-ethylphenyl)-(3,4'-diazidoquinazolin-4-yl)-amine; (3,4'-diazidoquinazolin-4-yl)-(3-
ethylphenyl)-amine; (3,4'-diazidoquinazolin-4-yl)-(3-ethylphenyl)-amine; (3-ethylphenyl)-(6-
methoxyquinazolin-4-yl)-(3-ethylphenyl)-amine; (3-ethylphenyl)-(6-carbomethoxyquinazolin-4-
yl)-(3-ethylphenyl)-amine; (3-ethylphenyl)-(6-carbomethoxyquinazolin-4-yl)-(3-ethylphenyl)-
amine; (6,7-bis(2-methoxyethoxy)quinazolin-4-yl)-(3-ethylphenyl)-amine; (3-azidophenyl)-(6,7-
dimethoxyquinazolin-4-yl)-amine; (3-azido-5-chlorophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine;
(4-azidophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-ethylphenyl)-(6-methansulfonyl-
quinazolin-4-yl)-amine; (6-ethansulfonyl-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6,7-dimethoxy-
quinazolin-4-yl)-(3-ethyl-4-fluoro-phenyl)-amine; (6,7-dimethoxy-quinazolin-4-yl)-[3-(propyn-
-yl)-phenyl]-amine; [6,7-bis(2-methoxy-ethoxy)-quinazolin-4-yl]-(5-ethyl-2-methyl-phenyl-
amine; [6,7-bis(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethyl-4-fluoro-phenyl)-amine; [6,7-bis-
(2-chloro-ethoxy)-quinazolin-4-yl]-(3-ethyl-phenyl)-amine; [6-(2-chloro-ethoxy)-7-(2-methoxy-
ethoxy)-quinazolin-4-yl]-(3-ethyl-phenyl)-amine; [6,7-bis(2-acetoxo-ethoxy)-quinazolin-4-yl]-(3-
ethyl-phenyl)-amine; 2-[4-(3-ethylphenylamino)-7-(2-hydroxy-ethoxy)-quinazolin-6-
yloxy]-
In a particular embodiment, the EGFR antagonist of formula I is N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine. 

In a particular embodiment, the EGFR antagonist N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is in HCl salt form. 

In another particular embodiment, the EGFR antagonist N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is in a substantially homogeneous crystalline polymorph form (described as...
polymorph B in WO 01/34,574) that exhibits an X-ray powder diffraction pattern having
characteristic peaks expressed in degrees 2-theta at approximately 6.26, 12.48, 13.39, 16.96, 20.20,
21.10, 22.98, 24.46, 25.14 and 26.91. Such polymorph form of N-(3-ethynylphenyl)-6,7-bis(2-
methoxyethoxy)-4-quinazolinamine is referred to as Tarceva™ as well as OSI-774, CP-358774 and
erlotinib.

The compounds of formula I, pharmaceutically acceptable salts and prodrugs thereof
(hereafter the active compounds) may be prepared by any process known to be applicable to the
preparation of chemically-related compounds. In general the active compounds may be made from
the appropriately substituted quinazoline using the appropriately substituted amine as shown in the
general scheme I disclosed in US 5,747,498:

Scheme I
As shown in Scheme I the appropriate 4-substituted quinazoline 2 wherein X is a suitable displaceable leaving group such as halo, aryloxy, alkylsulfmyl, alkylsulfonyl such as trifluoromethanesulfonyloxy, arylsulfiny1, arylsulfon1, siloxy, cyano, pyrazolo, triazolo or tetrazolo, preferably a 4-chloroquinazoline, is reacted with the appropriate amine or amine hydrochloride 4 or 5, wherein R4 is as described above and Y is Br, I, or trifluoromethane-sulfonyloxy in a solvent such as a (Ci-C4)alcohol, dimethylformamide (DMF), N-methylpyrrolidin-2-one, chloroform, acetonitrile, tetrahydrofuran (THF), 1-4 dioxane, pyridine or other aprotic solvent. The reaction may be effected in the presence of a base, preferably an alkali or alkaline earth metal carbonate or hydroxide or a tertiary amine base, such as pyridine, 2,6-lutidine, collidine, N-methyl-morpholine, triethylamine, 4-dimethylamino-pyridine or N,N-dimethylaniline. These bases are hereinafter referred to as suitable bases. The reaction mixture is maintained at a temperature from about ambient to about the reflux temperature of the solvent, preferably from about 35°C to about reflux, until substantially no remaining 4-haloquinazoline can be detected, typically about 2 to about 24 hours. Preferably, the reaction is performed under an inert atmosphere such as dry nitrogen.

Generally the reactants are combined stoichiometrically. When an amine base is used for those compounds where a salt (typically the HCl salt) of an amine 4 or 5 is used, it is preferable to use excess amine base, generally an extra equivalent of amine base. (Alternatively, if an amine base is not used an excess of the amine 4 or 5 may be used).

For those compounds where a sterically hindered amine 4 (such as a 2-alkyl-3-ethynylaniline) or very reactive 4-haloquinazoline is used it is preferable to use t-butyl alcohol or a polar aprotic solvent such as DMF or N-methylpyrrolidin-2-one as the solvent.

Alternatively, a 4-substituted quinazoline 2 wherein X is hydroxyl or oxo (and the 2-nitrogen is hydrogenated) is reacted with carbon tetrachloride and an optionally substituted triarylphosphine which is optionally supported on an inert polymer (e.g. triphenylphosphine, polymer supported, Aldrich Cat. No. 36,645-5, which is a 2% divinylbenzene cross-linked polystyrene containing 3 mmol phosphorous per gram resin) in a solvent such as carbon tetrachloride, chloroform, dichloroethane, tetrahydrofuran, acetonitrile or other aprotic solvent or mixtures thereof. The reaction mixture is maintained at a temperature from about ambient to reflux, preferably from about 35°C to reflux, for 2 to 24 hours. This mixture is reacted with the appropriate amine or amine hydrochloride 4 or 5 either directly or after removal of solvent, for example by vacuum evaporation, and addition of a suitable alternative solvent such as a (Ci-C4) alcohol, DMF, N-methylpyrrolidin-2-one, pyridine or 1-4 dioxane. Then, the reaction mixture is maintained at a temperature from about ambient to the reflux
temperature of the solvent preferably from about 35°C to about reflux, until substantially complete formation of product is achieved, typically from about 2 to about 24 hours. Preferably the reaction is performed under an inert atmosphere such as dry nitrogen.

When compound 4, wherein Y is Br, I, or trifluoromethanesulfonyloxy, is used as starting material in the reaction with quinazoline 2, a compound of formula 3 is formed wherein R^1, R^2, R^3, and Y are as described above. Compound 3 is converted to compounds of formula 1 wherein R^4 is R^{11} ethynyl, and R^{11} is as defined above, by reaction with a suitable palladium reagent such as tetrakis(triphenylphosphine)palladium or bis(triphenylphosphine)palladium dichloride in the presence of a suitable Lewis acid such as cuprous chloride and a suitable alkyne such as trimethylsilylacetylene, propargyl alcohol or 3-(N,N-dimethylamino)-propyne in a solvent such as diethylamine or triethylamine. Compounds 3, wherein Y is NH_2, may be converted to compounds 1 wherein R^4 is azide by treatment of compound 3 with a diazotizing agent, such as an acid and a nitrite (e.g., acetic acid and NaN_3) followed by treatment of the resulting product with an azide, such as NaN_3.

For the production of those compounds of Formula I wherein R^1 is an amino or hydroxyamino group the reduction of the corresponding Formula I compound wherein R^1 is nitro is employed.

The reduction may conveniently be carried out by any of the many procedures known for such transformations. The reduction may be carried out, for example, by hydrogenation of the nitro compound in a reaction-inert solvent in the presence of a suitable metal catalyst such as palladium, platinum or nickel. A further suitable reducing agent is, for example, an activated metal such as activated iron (produced by washing iron powder with a dilute solution of an acid such as hydrochloric acid). Thus, for example, the reduction may be carried out by heating a mixture of the nitro compound and the activated metal with concentrated hydrochloric acid in a solvent such as a mixture of water and an alcohol, for example, methanol or ethanol, to a temperature in the range, for example, 50° to 150° C, conveniently at or near 70°C. Another suitable class of reducing agents are the alkali metal dithionites, such as sodium dithionite, which may be used in (Ci-C_4)alkanoic acids, (Ci-C_6)alkanols, water or mixtures thereof.

For the production of those compounds of Formula I wherein R^2 or R^3 incorporates a primary or secondary amino moiety (other than the amino group intended to react with the quinazoline), such free amino group is preferably protected prior to the above described reaction followed by deprotection, subsequent to the above described reaction with 4-(substituted)quinazoline 2.

Several well known nitrogen protecting groups can be used. Such groups include (Ci-C_6)alkoxy carbonyl, optionally substituted benzylxycarbonyl, aryloxy carbonyl, trityl, vinylxycarbonyl, O-nitrophenylsulfonyl, diphenylphosphinyl, p-toluenesulfonyl, and benzyl. The addition of the nitrogen protecting group may be carried out in a chlorinated hydrocarbon solvent such as methylene chloride or 1,2-dichloroethane, or an ethereal solvent such as glyme, diglyme or THF, in
the presence or absence of a tertiary amine base such as triethylamine, diisopropylethylamine or pyridine, preferably triethylamine, at a temperature from about 0°C to about 50°C, preferably about ambient temperature. Alternatively, the protecting groups are conveniently attached using Schotten-Baumann conditions.

Subsequent to the above described coupling reaction, of compounds 2 and 5, the protecting group may be removed by deprotecting methods known to those skilled in the art such as treatment with trifluoroacetic acid in methylene chloride for the tert-butoxycarbonyl protected products.

For the production of compounds of Formula I wherein R^1 or R^2 is hydroxy, cleavage of a Formula I compound wherein R^1 or R^2 is (C_2-C_4)alkoxy is preferred.

The cleavage reaction may conveniently be carried out by any of the many procedures known for such a transformation. Treatment of the protected formula I derivative with molten pyridine hydrochloride (20-30 eq.) at 150° to 175°C may be employed for O-dealkylations. Alternatively, the cleavage reaction may be carried out, for example, by treatment of the protected quinazoline derivative with an alkali metal (C_i-C_j)alkylsulphide, such as sodium ethanethiolate or by treatment with an alkali metal diarylphosphide such as lithium diphenylphosphide. The cleavage reaction may also, conveniently, be carried out by treatment of the protected quinazoline derivative with a boron or aluminum trihalide such as boron tribromide. Such reactions are preferably carried out in the presence of a reaction-inert solvent at a suitable temperature.

Compounds of formula I, wherein R^1 or R^2 is a (C_i-C_j)alkylsulphinyl or (Q-C_j)alkylsulphonyl group are preferably prepared by oxidation of a formula I compound wherein R^1 or R^2 is a (C_i-C_j)alkylsulfinyl group. Suitable oxidizing agents are known in the art for the oxidation of sulfinyl to sulphinyl and/or sulphonyl, e.g., hydrogen peroxide, a peracid (such as 3-chloroperoxybenzoic or peroxyacetic acid), an alkali metal peroxy sulfatate (such as potassium peroxy monosulphate), chromium trioxide or gaseous oxygen in the presence of platinum. The oxidation is generally carried out under as mild conditions as possible using the stoichiometric amount of oxidizing agent in order to reduce the risk of over oxidation and damage to other functional groups. In general, the reaction is carried out in a suitable solvent such as methylene chloride, chloroform, acetone, tetrahydrofuran or tert-butyl methyl ether and at a temperature from about -25° to 50°C, preferably at or near ambient temperature, i.e., in the range of 15° to 35°C. When a compound carrying a sulphinyl group is desired a milder oxidizing agents should be used such as sodium or potassium metaperiodate, conveniently in a polar solvent such as acetic acid or ethanol. The compounds of formula I containing a (C_i-C_j)alkyl sulphinyl group may be obtained by oxidation of the corresponding (C_i-C_j)alkylsulphinyl compound as well as of the corresponding (C_i-C_j)alkylsulfonyl compound.

Compounds of formula I wherein R^1 is optionally substituted (C_2-C_4)alkanoylamino, ureido,
3-phenylureido, benzamido or sulfonamido can be prepared by acylation or sulfonylation of a corresponding compound wherein R\(^1\) is amino. Suitable acylating agents are any agents known in the art for the acylation of amino to acylamino, for example, acyl halides, e.g., a (C\(_2\)-C\(_4\)) alkanoyl chloride or bromide or a benzoyl chloride or bromide, alkanoic acid anhydrides or mixed anhydrides (e.g., acetic anhydride or the mixed anhydride formed by the reaction of an alkanoic acid and a (Q-C\(_4\)) alkoxy carbonyl halide, for example (Ci-C\(_4\)) alkoxy carbonyl chloride, in the presence of a suitable base. For the production of those compounds of Formula I wherein R\(^1\) is ureido or 3-phenylureido, a suitable acylating agent is, for example, a cyanate, e.g., an alkali metal cyanate such as sodium cyanate, or an isocyanate such as phenyl isocyanate. N-sulfonylations may be carried out with suitable sulfonyl halides or sulfonyl anhydrides in the presence of a tertiary amine base. In general the acylation or sulfonylation is carried out in a reaction-inert solvent and at a temperature in the range of about -30\(^\circ\) to 120\(^\circ\)C, conveniently at or near ambient temperature.

Compounds of Formula I wherein R\(^1\) is (C\(_1\)-C\(_4\)) alkoxy or substituted (C\(_1\)-C\(_4\)) alkoxy or R\(^1\) is (Ci-C\(_4\)) alkylamino or substituted mono-N- or di-N,N-(Ci-C\(_4\)) alkylamino, are prepared by the alkylation, preferably in the presence of a suitable base, of a corresponding compound wherein R\(^1\) is hydroxy or amino, respectively. Suitable alkylating agents include alkyl or substituted alkyl halides, for example, an optionally substituted (Ci-C\(_4\)) alkyl chloride, bromide or iodide, in the presence of a suitable base in a reaction-inert solvent and at a temperature in the range of about 10\(^\circ\) to 140\(^\circ\)C, conveniently at or near ambient temperature.

For the production of those compounds of Formula I wherein R\(^1\) is an amino-, oxy- or cyano-substituted (Ci-C\(_4\)) alkyl substituent, a corresponding compound wherein R\(^1\) is a (Ci-C\(_4\)) alkyl substituent bearing a group which is displaceable by an amino-, alkoxy-, or cyano group is reacted with an appropriate amine, alcohol or cyanide, preferably in the presence of a suitable base. The reaction is preferably carried out in a reaction-inert solvent or diluent and at a temperature in the range of about 10\(^\circ\) to 100\(^\circ\)C, preferably at or near ambient temperature.

Compounds of Formula I, wherein R\(^1\) is a carboxy substituent or a substituent which includes a carboxy group are prepared by hydrolysis of a corresponding compound wherein R\(^1\) is a (Ci-C\(_4\)) alkoxy carbonyl substituent or a substituent which includes a (Ci-C\(_4\)) alkoxy carbonyl group. The hydrolysis may conveniently be performed, for example, under basic conditions, e.g., in the presence of alkali metal hydroxide.

Compounds of Formula I wherein R\(^1\) is amino, (Ci-C\(_4\)) alkylamino, di-[(Ci-C\(_4\)) alkyl] amino, pyrrolidin-1-yl, piperidino, morpholino, piperazin-1-yl, 4-(Ci-C\(_4\)) alkyl piperazin-1-yl or (Ci-C\(_4\)) alkysulfanyl, may be prepared by the reaction, in the presence of a suitable base, of a corresponding compound wherein R\(^1\) is an amine or thiol displaceable group with an appropriate amine or thiol. The reaction is preferably carried out in a reaction-inert solvent or diluent and at a temperature in the range of about 10\(^\circ\) to 180\(^\circ\)C, conveniently in the range 100\(^\circ\) to 150\(^\circ\)C.

Compounds of Formula I wherein R\(^1\) is 2-oxopyrrolidin-1-yl or 2-oxopiperidin-1-yl are
prepared by the cyclisation, in the presence of a suitable base, of a corresponding compound wherein
R\textsuperscript{1} is a halo-\((C\textsubscript{2}-C\textsubscript{4})\)alkanoylamino group. The reaction is preferably carried out in a reaction-inert solvent or diluent and at a temperature in the range of about 10\(^\circ\) to 100\(^\circ\)C, conveniently at or near ambient temperature.

For the production of compounds of Formula I in which R\textsuperscript{1} is carbamoyl, substituted carbamoyl, alkanoyloxy or substituted alkanoyloxy, the carbamoylation or acylation of a corresponding compound wherein R\textsuperscript{1} is hydroxy is convenient.

Suitable acylating agents known in the art for acylation of hydroxyaryl moieties to alkanoyloxyaryl groups include, for example, (C\textsubscript{2}-C\textsubscript{4})alkanoyl halides, (C\textsubscript{2}-C\textsubscript{4})alkanoyl anhydrides and mixed anhydrides as described above, and suitable substituted derivatives thereof may be employed, typically in the presence of a suitable base. Alternatively, (C\textsubscript{2}-C\textsubscript{4})alkanoic acids or suitably substituted derivatives thereof may be coupled with a Formula I compound wherein R\textsuperscript{1} is hydroxy with the aid of a condensing agent such as a carbodiimide. For the production of those compounds of Formula I in which R\textsuperscript{1} is carbamoyl or substituted carbamoyl, suitable carbamoylating agents are, for example, cyanates or alkyl or arylisocyanates, typically in the presence of a suitable base.

Alternatively, suitable intermediates such as the chloroformate or carbonylimidazolyl derivative of a compound of Formula I in which R\textsuperscript{1} is hydroxy may be generated, for example, by treatment of said derivative with phosgene (or a phosgene equivalent) or carbonylazidazole. The resulting intermediate may then be reacted with an appropriate amine or substituted amine to produce the desired carbamoyl derivatives.

Compounds of formula I wherein R\textsuperscript{1} is aminocarbonyl or a substituted aminocarbonyl can be prepared by the aminolysis of a suitable intermediate in which R\textsuperscript{1} is carboxy.

The activation and coupling of formula I compounds wherein R\textsuperscript{1} is carboxy may be performed by a variety of methods known to those skilled in the art. Suitable methods include activation of the carboxyl as an acid halide, azide, symmetric or mixed anhydride, or active ester of appropriate reactivity for coupling with the desired amine. Examples of such types of intermediates and their production and use in couplings with amines may be found extensively in the literature; for example M. Bodansky and A. Bodansky, "The Practice of Peptide Synthesis", Springer-Verlag, New York, 1984. The resulting formula I compounds may be isolated and purified by standard methods, such as solvent removal and recrystallization or chromatography.

The starting materials for the described reaction scheme I (e.g., amines, quinazolines and amine protecting groups) are readily available or can be easily synthesized by those skilled in the art using conventional methods of organic synthesis. For example, the preparation of 2,3-dihydro-1,4-benzoazine derivatives are described in R. C. Elderfield, W. H. Todd, S. Gerber, Ch. 12 in "Heterocyclic Compounds", Vol. 6, R. C. Elderfield ed, John Wiley and Sons, Inc., N.Y., 1957. Substituted 2,3-dihydrobenzothiazinyl compounds are described by R. C. Elderfield and E. E. Harris in Ch. 13 of Volume 6 of the Elderfield "Heterocyclic Compounds" book.
In another particular embodiment, the EGFR antagonist has a general formula II as described in US 5,457,105, incorporated herein by reference:

wherein:

- m is 1, 2 or 3 and each R^1 is independently 6-hydroxy, 7-hydroxy, amino, carboxy, carbamoyl, ureido, (1-4C)alkoxycarbonyl, N-(1-4C)alkylcarbamoyl, N,N-di-(1-4C)alkyl carbamoyl, hydroxyamino, (1-4C)alkoxyamino, (2-4C)alkanoyloxyamino, trifluoromethoxy, (1-4C)alkyl, 6-(1-4C)alkoxy, 7-(1-4C)alkoxy, (1-3C)alkylenedioxy, (1-4C)alkylamino, di-l[(1-4C)alkyl]amino, pyrrolidin-1-yl, piperidino, morpholino, piperazin-1-yl, 4-(1-4C)alkylpiperazin-1-yl, (1-4C)alkylthio, (1-4C)alkylsulphinyl, (1-4C)alkylsulphonyl, bromomethyl, dibromomethyl, hydroxy-(1-4C)alkyl, (2-4C)alkanoyloxy-(1-4C)alkyl, (1-4C)alkoxy-(1-4C)alkyl, carboxy-(1-4C)alkyl, (1-4C)alkoxycarbonyl-(1-4C)alkyl, carbamoyl-(1-4C)alkyl, N-(1-4C)alkylcarbamoyl-(1-4C)alkyl, N,N-di-(1-4C)alkylcarbamoyl-(1-4C)alkyl, amino-(1-4C)alkyl, (1-4C)alkylamino-(1-4C)alkyl, di-[(1-4C)alkyl]amino-(1-4C)alkyl, piperidino-(1-4C)alkyl, morpholino-(1-4C)alkyl, piperazin-1-yl-(1-4C)alkyl, 4-(1-4C)alkylpiperazin-1-yl-(1-4C)alkyl, hydroxy-(2-4C)alkoxy-(1-4C)alkyl, (1-4C)alkoxy-(2-4C)alkoxy-(1-4C)alkyl, hydroxy-(2-4C)alkylamino-(1-4C)alkyl, (1-4C)alkoxy-(2-4C)alkylamino-(1-4C)alkyl, (1-4C)alkylthio-(1-4C)alkyl, hydroxy-(2-4C)alkylthio-(1-4C)alkyl, (1-4C)alkoxy-(2-4C)alkylthio-(1-4C)alkyl, anilino-(1-4C)alkyl, phenylthio-(1-4C)alkyl, cyano-(1-4C)alkyl, halogeno-(2-4C)alkoxy, hydroxy-(2-4C)alkoxy, (2-4C)alkanoyloxy-(2-4C)alkoxy, (1-4C)alkoxy-(2-4C)alkoxy, carboxy-(1-4C)alkoxy, (1-4C)alkoxycarbonyl-(1-4C)alkoxy, carbamoyl-(1-4C)alkoxy, N-(1-4C)alkylcarbamoyl-(1-4C)alkoxy, N,N-di-(1-4C)alkylcarbamoyl-(1-4C)alkoxy, amino-(2-4C)alkoxy, (1-4C)alkylamino-(2-4C)alkoxy, di-[(1-4C)alkyl]amino-(2-4C)alkoxy, (2-4C)alkanoyloxy, hydroxy-(2-4C)alkanoyloxy, (1-4C)alkoxy-(2-4C)alkanoyloxy, phenyl-(1-4C)alkoxy, phenoxy-(2-4C)alkoxy, anilino-(2-4C)alkoxy, phenylthio-(2-4C)alkoxy, piperidino-(2-4C)alkoxy, morpholino-(2-4C)alkoxy, piperazin-1-yl-(2-4C)alkoxy, 4-(1-4C)alkylpiperazin-1-yl-(2-4C)alkoxy, halogeno-(2-4C)alkylamino, hydroxy-(2-4C)alkylamino, (2-4C)alkanoyloxy-(2-4C)alkylamino, (1-4C)alkoxy-(2-4C)alkylamino, carboxy-(1-4C)alkylamino, (1-4C)alkoxycarbonyl-(1-4C)alkylamino, carbamoyl-(1-4C)alkylamino, N-(1-4C)alkylcarbamoyl-(1-4C)alkylamino, N,N-
di-[l-4C)alkyl]carbamoyl-(l-4C)alkylamino, amino-(2-4C)alkylamino, (I-4C)alkylamino-(2-4C)alkylamino, di-[l-(4C)alkyl]amino-(2-4C)alkylamino, phenyl-(l-4C)alkylamino, phenoxy-(l-4C)alkylamino, anilino-(2-4C)alkylamino, phenylthio-(2-4C)alkylamino, (2-4C)alkanoylaminol, (1-4C)alkoxycarbonylamino, (l-4C)alkylsulphonylamino, benzamido, benzenesulphonamido, 3-phenyleureido, 2-oxopyrrolidin-1-yl, 2,5-dioxopyrrolidin-1-yl, halogeno-(2-4C)alkanoylaminol, hydroxy-(2-4C)alkanoylaminol, (l-4C)alkoxy-(2-4C)alkanoylaminol, carboxy-(2-4C)alkanoylaminol, (1-4C)alkoxycarbonyl-(2-4C)alkanoylaminol, carbamoyl-(2-4C)alkanoylaminol, N-(1-4C)alkylcarbamoyl-(2-4C)alkanoylaminol, N,N-di-[l-4C)alkyl]carbamoyl-(2-4C)alkanoylaminol, amino-(2-4C)alkanoylaminol, (l-4C)alkylaminol-(2-4C)alkanoylaminol or di-[l-(4C)alkyl]aminol-(2-4C)alkanoylaminol, and wherein said benzamido or benzenesulphonamido substituent or any anilino, phenoxy or phenyl group in a R⁻ substitution may optionally bear one or two halogeno, (l-4C)alkyl or (l-4C)alkoxy substituents;

n is 1 or 2 and
each R² is independently hydrogen, hydroxy, halogeno, trifluoromethyl, amino, nitro, cyano, (l-4C)alkyl, (l-4C)alkoxy, (l-4C)alkylamino, di-[l-(4C)alkyl] amino, (l-4C)alkylthio, (l-4C)alkylsulphynil or (l-4C)alkylsulphonyl; or a pharmaceutically-acceptable salt thereof; except that 4-(4'-hydroxyanilino)-6-methoxyquinazoline, 4-(4',hydroxyanilino)-6,7-methylenedioxyquinazoline, 6-amino-4-(4'-aminoanilino)quinazoline, 4-anilino-6-methylquinazoline or the hydrochloride salt thereof and 4-anilino-6,7-dimethoxyquinazoline or the hydrochloride salt thereof are excluded.

In a particular embodiment, the EGFR antagonist is a compound according to formula II selected from the group consisting of: 4-(3'-chloro-4'-fluoroanilino)-6,7-dimethoxyquinazoline; 4-(3',4'-dichloroanilino)-6,7-dimethoxyquinazoline; 6,7-dimethoxy-4-(3'-nitroanilino)-quinazoline; 6,7-diethoxy-4-(3'-methylanilino)-quinazoline; 6-methoxy-4-(3'-methylanilino)-quinazoline; 4-(3'-chloroanilino)-6-methoxyquinazoline; 6,7-ethylenedioxy-4-(3'-methylanilino)-quinazoline; 6-amino-7-methoxy-4-(3'-methylanilino)-quinazoline; 4-(3'-methylanilino)-6-ureidoquinazoline; 6-(2-methoxyethoxymethyl)-4-(3'-methylanilino)-quinazoline; 6,7-di-(2-methoxyethoxy)4-(3'-methylanilino)-quinazoline; 6-dimethyamino-4-(3'-methylanilino)quinazoline; 6-benzamido-4-(3'-methylanilino)quinazoline; 6,7-dimethoxy-4-(3'-trifluoromethylanilino)-quinazoline; 6-hydroxy-7-methoxy-4-(3'-methylanilino)-quinazoline; 7-hydroxy-6-methoxy-4-(3'-methylanilino)-quinazoline; 7-amino-4-(3'-methylanilino)-quinazoline; 6-amino-4-(3'-methylanilino)quinazoline; 6-acetamido-4-(3'-methylanilino)quinazoline; 6-(2-methoxyethylamino)-4-(3'-methylanilino)-quinazoline; 7-(2-methoxyacetamido)-4-(3'-methylanilino)-quinazoline; 7-(2-hydroxyethoxy)-6-methoxy-4-(3'-methylanilino)-quinazoline; 7-(2-methoxyethoxy)-6-methoxy-4-(3'-methylanilino)-quinazoline; 6-amino-4-(3'-methylanilino)-quinazoline.

A quinazoline derivative of the formula II, or a pharmaceutically-acceptable salt thereof, may be prepared by any process known to be applicable to the preparation of chemically-related compounds. A suitable process is, for example, illustrated by that used in US 4,322,420. Necessary
starting materials may be commercially available or obtained by standard procedures of organic chemistry.

(a) The reaction, conveniently in the presence of a suitable base, of a quinazoline (i), wherein 
Z is a displaceable group, with an aniline (ii).

\[
\begin{align*}
&\text{(i)} \quad \begin{array}{c}
\text{Z} \\
\text{H} \\
\text{N} \\
\text{N} \\
\text{R}_1^n
\end{array} \\
&\text{(ii)} \quad \begin{array}{c}
\text{H}_2\text{N} \\
\text{R}_2^n
\end{array}
\end{align*}
\]

A suitable displaceable group Z is, for example, a halogeno, alkoxy, aryloxy or sulphonyloxy group, for example a chloro, bromo, methoxy, phenoxy, methanesulphonyloxy or toluene-p-sulphonyloxy group.

A suitable base is, for example, an organic amine base such as, for example, pyridine, 2,6-lutidine, collidine, 4-dimethylaminopyridine, triethylamine, morpholine, N-methylmorpholine or diazabicyclo[5.4.0]undec-7-ene, or for example, an alkali or alkaline earth metal carbonate or hydroxide, for example sodium carbonate, potassium carbonate, calcium carbonate, sodium hydroxide or potassium hydroxide.

The reaction is preferably carried out in the presence of a suitable inert solvent or diluent, for example an alkanol or ester such as methanol, ethanol, isopropanol or ethyl acetate, a halogenated solvent such as methylene chloride, chloroform or carbon tetrachloride, an ether such as tetrahydrofuran or 1,4-dioxan, an aromatic solvent such as toluene, or a dipolar aprotic solvent such as N,N-dimethylformamide, N,N-dimethylacetamide, N-methylpyrrolidin-2-one or dimethylsulphoxide. The reaction is conveniently carried out at a temperature in the range, for example, 10° to 150°C, preferably in the range 20° to 80°C.

The quinazoline derivative of the formula II may be obtained from this process in the form of the free base or alternatively it may be obtained in the form of a salt with the acid of the formula H-Z wherein Z has the meaning defined hereinbefore. When it is desired to obtain the free base from the salt, the salt may be treated with a suitable base as defined hereinbefore using a conventional procedure.

(b) For the production of those compounds of the formula II wherein R⁴ or R⁵ is hydroxy, the cleavage of a quinazoline derivative of the formula II wherein R⁴ or R⁵ is (1-4C)alkoxy.

The cleavage reaction may conveniently be carried out by any of the many procedures known for such a transformation. The reaction may be carried out, for example, by treatment of the quinazoline derivative with an alkali metal (1-4C)alkyl sulphide such as sodium ethanethiolate or, for example, by treatment with an alkali metal diarylphosphide such as lithium diphenylphosphide. Alternatively the cleavage reaction may conveniently be carried out, for example, by treatment of the quinazoline derivative with a boron or aluminium trihalide such as boron tribromide. Such reactions
are preferably carried out in the presence of a suitable inert solvent or diluent as defined hereinbefore and at a suitable temperature.

(c) For the production of those compounds of the formula II wherein \( R^1 \) or \( R^2 \) is a (1-4C)alkylsulphinyl or (1-4C)alkylsulphonyl group, the oxidation of a quinazoline derivative of the formula II wherein \( R^1 \) or \( R^2 \) is a (1-4C)alkythio group.

A suitable oxidising agent is, for example, any agent known in the art for the oxidation of thio to sulphinyl and/or sulphonyl, for example, hydrogen peroxide, a peracid (such as 3-chloroperoxybenzoic or peroxyacetic acid), an alkali metal peroxydisulphate (such as potassium peroxymonosulphate), chromium trioxide or gaseous oxygen in the presence of platinium. The oxidation is generally carried out under as mild conditions as possible and with the required stoichiometric amount of oxidising agent in order to reduce the risk of over oxidation and damage to other functional groups. In general the reaction is carried out in a suitable solvent or diluent such as methylene chloride, chloroform, acetone, tetrahydrofuran or tert-butyl methyl ether and at a temperature, for example, -25°C to 50°C, conveniently at or near ambient temperature, that is in the range 15°C to 35°C. When a compound carrying a sulphinyl group is required a milder oxidising agent may also be used, for example sodium or potassium metaperiodate, conveniently in a polar solvent such as acetic acid or ethanol. It will be appreciated that when a compound of the formula II containing a (1-4C)alkylsulphonyl group is required, it may be obtained by oxidation of the corresponding (1-4C)alkylsulphinyl compound as well as of the corresponding (1-4C)alkythio compound.

(d) For the production of those compounds of the formula II wherein \( R^1 \) is amino, the reduction of a quinazoline derivative of the formula I wherein \( R^1 \) is nitro.

The reduction may conveniently be carried out by any of the many procedures known for such a transformation. The reduction may be carried out, for example, by the hydrogenation of a solution of the nitro compound in an inert solvent or diluent as defined hereinbefore in the presence of a suitable metal catalyst such as palladium or platinum. A further suitable reducing agent is, for example, an activated metal such as activated iron (produced by washing iron powder with a dilute solution of an acid such as hydrochloric acid). Thus, for example, the reduction may be carried out by heating a mixture of the nitro compound and the activated metal in a suitable solvent or diluent such as a mixture of water and an alcohol, for example, methanol or ethanol, to a temperature in the range, for example, 50°C to 150°C, conveniently at or near 70°C.

(e) For the production of those compounds of the formula II wherein \( R^1 \) is (2-4C)alkanoylamino or substituted (2-4C)alkanoylamino, ureido, 3-phenylureido or benzamido, or \( R^2 \) is acetamido or benzamido, the acylation of a quinazoline derivative of the formula II wherein \( R^1 \) or \( R^2 \) is amino.

A suitable acylating agent is, for example, any agent known in the art for the acylation of amino to acylamino, for example an acyl halide, for example a (2-4C)alkanoyl chloride or bromide or
a benzoyl chloride or bromide, conveniently in the presence of a suitable base, as defined hereinbefore, an alkanoic acid anhydride or mixed anhydride, for example a (2-4C)alkanoic acid anhydride such as acetic anhydride or the mixed anhydride formed by the reaction of an alkanoic acid and a (1-4C)alkoxycarbonyl halide, for example a (1-4C)alkoxycarbonyl chloride, in the presence of a suitable base as defined hereinbefore. For the production of those compounds of the formula II wherein R₁ is ureido or 3-phenylureido, a suitable acylating agent is, for example, a cyanate, for example an alkali metal cyanate such as sodium cyanate or, for example, an isocyanate such as phenyl isocyanate. In general the acylation is carried out in a suitable inert solvent or diluent as defined hereinbefore and at a temperature, in the range, for example, -30° to 120°C, conveniently at or near ambient temperature.

(f) For the production of those compounds of the formula II wherein R₁ is (1-4C)alkoxy or substituted (1-4C)alkoxy or R₁ is (1-4C)alkylamino or substituted (1-4C)alkylamino, the alkylation, preferably in the presence of a suitable base as defined hereinbefore, of a quinazoline derivative of the formula II wherein R₁ is hydroxy or amino as appropriate.

A suitable alkylation agent is, for example, any agent known in the art for the alkylation of hydroxy to alkoxy or substituted alkoxy, or for the alkylation of amino to alkylamino or substituted alkylamino, for example an alkyl or substituted alkyl halide, for example a (1-4C)alkyl chloride, bromide or iodide or a substituted (1-4C)alkyl chloride, bromide or iodide, in the presence of a suitable base as defined hereinbefore, in a suitable inert solvent or diluent as defined hereinbefore and at a temperature in the range, for example, 10° to 140°C, conveniently at or near ambient temperature.

(g) For the production of those compounds of the formula II wherein R₁ is a carboxy substituent or a substituent which includes a carboxy group, the hydrolysis of a quinazoline derivative of the formula II wherein R₁ is a (1-4C)alkoxycarbonyl substituent or a substituent which includes a (1-4C)alkoxycarbonyl group.

The hydrolysis may conveniently be performed, for example, under basic conditions.

(h) For the production of those compounds of the formula II wherein R₁ is an amino-, oxy-, thio- or cyano-substituted (1-4C)alkyl substituent, the reaction, preferably in the presence of a suitable base as defined hereinbefore, of a quinazoline derivative of the formula II wherein R₁ is a (1-4C)alkyl substituent bearing a displaceable group as defined hereinbefore with an appropriate amine, alcohol, thiol or cyanide.

The reaction is preferably carried out in a suitable inert solvent or diluent as defined hereinbefore and at a temperature in the range, for example, 10° to 100°C, conveniently at or near ambient temperature.

When a pharmaceutically-acceptable salt of a quinazoline derivative of the formula II is required, it may be obtained, for example, by reaction of said compound with, for example, a suitable acid using a conventional procedure.
In a particular embodiment, the EGFR antagonist is a compound according to formula II' as disclosed in US 5,770,599, incorporated herein by reference:

![Chemical Structure](image)

wherein:

n is 1, 2 or 3;

each R² is independently halogeno or trifluoromethyl

R³ is (1-4C)alkoxy; and

R¹ is di-[(1-4C)alkyl]amino-(2-4C)alkoxy, pyrrolidin-l-yl-(2-4C)alkoxy, piperidino-(2-4C)alkoxy, morpholino-(2-4C)alkoxy, piperazin-l-yl-(2-4C)alkoxy, 4-(1-4C)alkyipiperazin-l-yl-(2-4C)alkoxy, imidazol-l-yl-(2-4C)alkoxy, di-[(1-4C)alkoxy-(2-4C)alkyl]amino-(2-4C)alkoxy, thiamorpholino-(2-4C)alkoxy, l-oxothiamorpholino-(2-4C)alkoxy or 1,1-dioxothiamorpholino-(2-4C)alkoxy, and wherein any of the above mentioned R¹ substituents comprising a CH₂ (methylene) group which is not attached to a N or O atom optionally bears on said CH₂ group a hydroxy substituent;

or a pharmaceutically-acceptable salt thereof.

In a particular embodiment, the EGFR antagonist is a compound according to formula II' selected from the group consisting of: 4-(3'-chloro-4'-fluoroanilino)-7-methoxy-6-(2-pyrrolidin-l-ylethoxy)-quinazoline; 4-(3'-chloro-4'-fluoroanilino)-7-methoxy-6-(2-morpholinoethoxy)-quinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(3-diethylaminopropoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-7-methoxy-6-(3-diethylaminopropoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-7-methoxy-6-(3-morpholinopropoxy)-7-methoxyquinazoline; 4-(3',4'-difluoroanilino)-6-(3-morpholinopropoxy)-7-methoxyquinazoline; 4-(3',4'-difluoroanilino)-7-methoxy-6-(3-morpholinopropoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(2-imidazol-l-ylethoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(2-imidazol-l-ylethoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(3-imidazol-l-ylpropoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(3-imidazol-l-ylpropoxy)-7-methoxyquinazoline; 4-(2',4'-difluoroanilino)-6-(3-methylaminopropoxy)-7-methoxyquinazoline; 4-(2',4'-difluoroanilino)-6-(3-methylaminopropoxy)-7-methoxyquinazoline; 4-(2',4'-difluoroanilino)-7-methoxy-6-(3-methylaminopropoxy)-quinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(2-imidazol-l-ylethoxy)-7-methoxyquinazoline; 4-(3'-chloro-4'-fluoroanilino)-6-(2-imidazol-l-ylethoxy)-7-methoxyquinazoline; and 4-(3'-chloro-4'-fluoroanilino)-6-(3-imidazol-l-ylpropoxy)-7-methoxyquinazoline.
In a particular embodiment, the EGFR antagonist is a compound according to formula II' that is 4-(3'-chloro-4'-fluoroanilino)-7-methoxy-6-(3-morpholinopropoxy)-quinazoline, alternatively referred to as ZD 1839, gefitinib and Iressa®.

A quinazoline derivative of the formula II', or a pharmaceutically-acceptable salt thereof, may be prepared by any process known to be applicable to the preparation of chemically-related compounds. Suitable processes include, for example, those illustrated in US5616582, US 5580870, US 5475001 and US5556968. Unless otherwise stated, n, R², R³ and R¹ have any of the meanings defined hereinbefore for a quinazoline derivative of the formula II'. Necessary starting materials may be commercially available or obtained by standard procedures of organic chemistry.

(a) The reaction, conveniently in the presence of a suitable base, of a quinazoline (iii) wherein Z is a displaceable group, with an aniline (iv)

![Chemical structure]

A suitable displaceable group Z is, for example, a halogeno, alkoxy, aryloxy or sulphonyloxy group, for example a chloro, bromo, methoxy, phenoxy, methanesulphonyloxy or toluene-4-sulphonyloxy group.

A suitable base is, for example, an organic amine base such as, for example, pyridine, 2,6-lutidine, collidine, 4-dimethylaminopyridine, triethylamine, morpholine, N-methylmorpholine or diazabicyclo[5.4.0]undec-7-ene, or for example, an alkali or alkaline earth metal carbonate or hydroxide, for example sodium carbonate, potassium carbonate, calcium carbonate, sodium hydroxide or potassium hydroxide. Alternatively a suitable base is, for example, an alkali metal or alkaline earth metal amide, for example sodium amide or sodium bis(trimethylsilyl)amide.

The reaction is preferably carried out in the presence of a suitable inert solvent or diluent, for example an alkanol or ester such as methanol, ethanol, isopropanol or ethyl acetate, a halogenated solvent such as methylene chloride, chloroform or carbon tetrachloride, an ether such as tetrahydrofuran or 1,4-dioxan, an aromatic solvent such as toluene, or a dipolar aprotic solvent such as N,N-dimethylformamide, N,N-dimethylacetamide, N-methylpyrrolidin-2-one or dimethylsulphoxide. The reaction is conveniently carried out at a temperature in the range, for example, 10°C to 150°C, preferably in the range 20°C to 80°C.

The quinazoline derivative of the formula II' may be obtained from this process in the form of the free base or alternatively it may be obtained in the form of a salt with the acid of the formula H-Z wherein Z has the meaning defined hereinbefore. When it is desired to obtain the free base from the salt, the salt may be treated with a suitable base as defined hereinbefore using a conventional procedure.
(b) For the production of those compounds of the formula II’ wherein R\textsuperscript{1} is an amino-substituted (2-4C)alkoxy group, the alkylation, conveniently in the presence of a suitable base as defined hereinbefore, of a quinazoline derivative of the formula II’ wherein R\textsuperscript{1} is a hydroxy group.

A suitable alkylation agent is, for example, any agent known in the art for the alkylation of hydroxy to amino-substituted alkoxy, for example an amino-substituted alkyl chloride, bromide or iodide, in the presence of a suitable base as defined hereinbefore, in a suitable inert solvent or diluent as defined hereinbefore and at a temperature in the range, for example, 10\textdegree{} to 140\textdegree{}C, conveniently at or near 80\textdegree{}C.

(c) For the production of those compounds of the formula II’ wherein R\textsuperscript{1} is an amino-substituted (2-4C)alkoxy group, the reaction, conveniently in the presence of a suitable base as defined hereinbefore, of a compound of the formula II’ wherein R\textsuperscript{1} is a hydroxy-(2-4C)alkoxy group, or a reactive derivative thereof, with an appropriate amine.

A suitable reactive derivative of a compound of the formula II’ wherein R\textsuperscript{1} is a hydroxy-(2-4C)alkoxy group is, for example, a halogeno- or sulphonyloxy-(2-4C)alkoxy group such as a bromo- or methanesulphonyloxy-(2-4C)alkoxy group.

The reaction is preferably carried out in the presence of a suitable inert solvent or diluent as defined hereinbefore and at a temperature in the range, for example, 10\textdegree{} to 150\textdegree{}C, conveniently at or near 50\textdegree{}C.

(d) For the production of those compounds of the formula II’ wherein R\textsuperscript{1} is a hydroxy-amino-(2-4C)alkoxy group, the reaction of a compound of the formula II’ wherein R\textsuperscript{1} is a 2,3-epoxypropoxy or 3,4-epoxybutoxy group with an appropriate amine.

The reaction is preferably carried out in the presence of a suitable inert solvent or diluent as defined hereinbefore and at a temperature in the range, for example, 10\textdegree{} to 150\textdegree{}C, conveniently at or near 70\textdegree{}C.

When a pharmaceutically-acceptable salt of a quinazoline derivative of the formula II’ is required, for example a mono- or di-acid-addition salt of a quinazoline derivative of the formula II’, it may be obtained, for example, by reaction of said compound with, for example, a suitable acid using a conventional procedure.

In a particular embodiment, the EGFR antagonist is a compound according to formula III as disclosed in WO9935146, incorporated herein by reference:
or a salt or solvate thereof; wherein
X is N or CH;
Y is CR\textsuperscript{1} and V is N;
or Y is N and V is CR\textsuperscript{1};
or Y is CR\textsuperscript{1} and V is CR\textsuperscript{2};
or Y is CR\textsuperscript{2} and V is CR\textsuperscript{1};
R\textsuperscript{1} represents a group CH\textsubscript{3}SO\textsubscript{2}CH\textsubscript{2}CH\textsubscript{2}NHCH\textsubscript{2}-Ar-., wherein Ar is selected from phenyl, furan, thiophene, pyrrole and thiazole, each of which may optionally be substituted by one or two halo, C\textsubscript{1-4}alkyl or C\textsubscript{1-4}alkoxy groups;
R\textsuperscript{2} is selected from the group comprising hydrogen, halo, hydroxy, C\textsubscript{1-4}alkyl, C\textsubscript{1-4}alkoxy, C\textsubscript{1-4}alkylamino and di[C\textsubscript{1-4}alkyl]amino;
U represents a phenyl, pyridyl, 3H-imidazolyl, indolyl, isoindolyl, indolinylyl, isoindolinylyl, IH-indazolyl, 2,3-dihydro-IH-indazolyl, IH-benzimidazolyl, 2,3-dihydro-IH-benzimidazolyl or IH-benzotriazolyl group, substituted by an R\textsuperscript{2} group and optionally substituted by at least one independently selected R\textsuperscript{4} group;
R\textsuperscript{3} is selected from a group comprising benzyl, halo-, dihalo- and trihalobenzyl, benzoyl, pyridymethyl, pyridylmethoxy, phenoxy, benzyloxy, halo-, dihalo- and trihalobenzyloxy and benzenesulphonyl; or R\textsuperscript{3} represents trihalomethylbenzyl or trihalomethylbenzyloxy;
or R\textsuperscript{3} represents a group of formula
\[
\begin{array}{c}
\text{N} \\
\text{(R\textsuperscript{5})_n}
\end{array}
\]
wherein each R\textsuperscript{5} is independently selected from halogen, C\textsubscript{1-4}alkyl and Q\textsubscript{4}alkoxy; and n is 0 to 3; and
each R\textsuperscript{4} is independently hydroxy, halogen, Q\textsubscript{4}alkyl, C\textsubscript{2-4}alkenyl, C\textsubscript{2-4}alkynyl, C\textsubscript{1-4}alkoxy, amino, C\textsubscript{1-4}alkylamino, di[C\textsubscript{1-4}alkyl]amino, Cl-alkylthio, Cl-alkylsulphinyl, C\textsubscript{1-4}alkylsulphonyl, C\textsubscript{1-4}alkylcarbonyl, carboxy, carbamoyl, C\textsubscript{1-4}alkoxycarbonyl, C\textsubscript{1-4}alkylamino, N-(C\textsubscript{1-4}alkyl)carbamoyl, N,N-di(C\textsubscript{1-4}alkyl)carbamoyl, cyano, nitro and trifluoromethyl.

In a particular embodiment, EGFR antagonists of formula III exclude: (1-Benzyl-IH-indazol-5-yl)-(6-(5-((2-methanesulphonyl-ethylamino)-methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl-amine; (4-Benzoxoy-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)-methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl-amine; (1-Benzyl-IH-indazol-5-yl)-(6-(5-((2-methanesulphonyl-ethylamino)-methyl)-furan-2-yl)-quinazolin-4-yl-amine; (1-Benzyl H-indazol-5-yl)-(7-(5-((2-methanesulphonyl-ethylamino)-methyl)-furan-2-yl)-quinazolin-4-yl-amine; and (1-Benzyl-IH-
In a particular embodiment, the EGFR antagonist of formula III are selected from the group consisting of: 4-(4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine; (4-Fluorobenzylamino)-phenyl)-(6-(5-((2-methanesulphonyl-ethylamino)methyl)-furan-2-yl)-pyrido[3,4-d]pyrimidin-4-yl)-amine;
l,3-thiazol-4-yl]-4-quinazolinamine; N-(3-Fluoro-4-benzyloxyphenyl)-6-[[2-(methanesulphonyl)ethyl]amino)methyl]-1,3-thiazol-4-yl]-4-quinazolinamine; N-(3-Chloro-4-benzyloxyphenyl)-6-[[2-(methanesulphonyl)ethyl]amino)methyl]-1,3-thiazol-4-yl]-4-quinazolinamine; N-(3-Chloro-4-[(3-fluorobenzyl)oxy]phenyl)-6-[[5-[[2-(methanesulphonyl)ethyl]amino)methyl]-2-furyl]4-quinazolinamine; N-(3-Chloro-4-[(3-fluorobenzyl)oxy]phenyl)-6-[[5-[[2-(methanesulphonyl)ethyl]amino)methyl]-2-furyl]4-quinazolinamine; and salts and solvates thereof.

In a particular embodiment, the EGFR antagonist is: N-[3-chloro-4-[(3-fluorophenyl)methoxy]phenyl]-6-[[5-[[2-(methylsulfonyl)ethyl]amino)methyl]-2-furyl]4-quinazolinamine ditosylate salt (lapatinib).

In a particular embodiment, the EGFR antagonist is a compound according to formula IV as disclosed in WO132651, incorporated herein by reference:

![IV](image)

wherein:

m is an integer from 1 to 3;
R represents halogeno or C_{1-3}alkyl;
X represents -0-;
R is selected from one of the following three groups:
1) C_{1-3}alkylR (wherein R is piperidin-4-yl which may bear one or two substituents selected from hydroxy, halogeno, C_{1-4}alkyl, C_{1-4}hydroxyalkyl and C_{1-4}alkoxy;
2) C_{2-3}alkenylR (wherein R is as defined herein);
3) C_{2-3}alkynylR (wherein R is as defined herein),
and wherein any alkyl, alkenyl or alkynyl group may bear one or more substituents selected from hydroxy, halogeno and amino; or a salt thereof.

In a particular embodiment, the EGFR antagonist is selected from the group consisting of: 4-(4-chloro-2-fluoroanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline; 4-(2-fluoro-4-methylanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline; 4-(4-bromo-2-fluoroanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline; 4-(4-chloro-2,6-difluoroanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline; 4-(4-bromo-2,6-difluoroanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline; 4-(4-chloro-2-fluoroanilino)-6-methoxy-7-(piperidin-4-ylmethoxy)quinazoline; 4-(2-fluoro-4-methylanilino)-6-methoxy-7-(piperidin-4-ylmethoxy)quinazoline; 4-(4-bromo-2-fluoroanilino)-6-methoxy-7-(piperidin-4-ylmethoxy)quinazoline; 4-(4-chloro-2,6-difluoroanilino)-6-methoxy-7-(piperidin-4-ylmethoxy)quinazoline; 4-(4-bromo-2,6-difluoroanilino)-6-methoxy-7-(piperidin-4-ylmethoxy)quinazoline; and pharmaceutically acceptable salts and solvates thereof.

In a particular embodiment, the EGFR antagonist is 4-(4-bromo-2-fluoroanilino)-6-methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline (Zactina) and salts thereof.

**Combination Therapies**

The present invention features the combination use of a c-met antagonist and an EGFR antagonist as part of a specific treatment regimen intended to provide a beneficial effect from the combined activity of these therapeutic agents. The beneficial effect of the combination includes, but is not limited to, pharmacokinetic or pharmacodynamic co-action resulting from the combination of therapeutic agents. The present invention is particularly useful in treating cancers of various types at various stages.

The term cancer embraces a collection of proliferative disorders, including but not limited to pre-cancerous growths, benign tumors, and malignant tumors. Benign tumors remain localized at the site of origin and do not have the capacity to infiltrate, invade, or metastasize to distant sites. Malignant tumors will invade and damage other tissues around them. They can also gain the ability to break off from the original site and spread to other parts of the body (metastasize), usually through the bloodstream or through the lymphatic system where the lymph nodes are located. Primary tumors are classified by the type of tissue from which they arise; metastatic tumors are classified by the tissue type from which the cancer cells are derived. Over time, the cells of a malignant tumor become more abnormal and appear less like normal cells. This change in the appearance of cancer cells is called the tumor grade, and cancer cells are described as being well-differentiated (low grade), moderately-differentiated, poorly-differentiated, or undifferentiated (high grade). Well-differentiated cells are quite normal appearing and resemble the normal cells from which they originated. Undifferentiated cells are cells that have become so abnormal that it is no longer possible to determine the origin of the cells.

Cancer staging systems describe how far the cancer has spread anatomically and attempt to
put patients with similar prognosis and treatment in the same staging group. Several tests may be performed to help stage cancer including biopsy and certain imaging tests such as a chest x-ray, mammogram, bone scan, CT scan, and MRI scan. Blood tests and a clinical evaluation are also used to evaluate a patient's overall health and detect whether the cancer has spread to certain organs.

To stage cancer, the American Joint Committee on Cancer first places the cancer, particularly solid tumors, in a letter category using the TNM classification system. Cancers are designated the letter T (tumor size), N (palpable nodes), and/or M (metastases). T1, T2, T3, and T4 describe the increasing size of the primary lesion; NO, N1, N2, N3 indicates progressively advancing node involvement; and MO and M1 reflect the absence or presence of distant metastases.

In the second staging method, also known as the Overall Stage Grouping or Roman Numeral Staging, cancers are divided into stages 0 to IV, incorporating the size of primary lesions as well as the presence of nodal spread and of distant metastases. In this system, cases are grouped into four stages denoted by Roman numerals I through IV, or are classified as "recurrent." For some cancers, stage 0 is referred to as "in situ" or "Tis," such as ductal carcinoma in situ or lobular carcinoma in situ for breast cancers. High grade adenomas can also be classified as stage 0. In general, stage I cancers are small localized cancers that are usually curable, while stage IV usually represents inoperable or metastatic cancer. Stage II and III cancers are usually locally advanced and/or exhibit involvement of local lymph nodes. In general, the higher stage numbers indicate more extensive disease, including greater tumor size and/or spread of the cancer to nearby lymph nodes and/or organs adjacent to the primary tumor. These stages are defined precisely, but the definition is different for each kind of cancer and is known to the skilled artisan.

Many cancer registries, such as the NCI's Surveillance, Epidemiology, and End Results Program (SEER), use summary staging. This system is used for all types of cancer. It groups cancer cases into five main categories:

**In situ** is early cancer that is present only in the layer of cells in which it began.

**Localized** is cancer that is limited to the organ in which it began, without evidence of spread.

**Regional** is cancer that has spread beyond the original (primary) site to nearby lymph nodes or organs and tissues.

**Distant** is cancer that has spread from the primary site to distant organs or distant lymph nodes.

**Unknown** is used to describe cases for which there is not enough information to indicate a stage.

In addition, it is common for cancer to return months or years after the primary tumor has been removed. Cancer that recurs after all visible tumor has been eradicated, is called recurrent disease. Disease that recurs in the area of the primary tumor is locally recurrent, and disease that recurs as metastases is referred to as a distant recurrence.

The tumor can be a solid tumor or a non-solid or soft tissue tumor. Examples of soft tissue...
tumors include leukemia (e.g., chronic myelogenous leukemia, acute myelogenous leukemia, adult acute lymphoblastic leukemia, acute myelogenous leukemia, mature B-cell acute lymphoblastic leukemia, chronic lymphocytic leukemia, polymorphocytic leukemia, or hairy cell leukemia) or lymphoma (e.g., non-Hodgkin’s lymphoma, cutaneous T-cell lymphoma, or Hodgkin’s disease). A solid tumor includes any cancer of body tissues other than blood, bone marrow, or the lymphatic system. Solid tumors can be further divided into those of epithelial cell origin and those of non-epithelial cell origin. Examples of epithelial cell solid tumors include tumors of the gastrointestinal tract, colon, breast, prostate, lung, kidney, liver, pancreas, ovary, head and neck, oral cavity, stomach, duodenum, small intestine, large intestine, anus, gall bladder, labium, nasopharynx, skin, uterus, male genital organ, urinary organs, bladder, and skin. Solid tumors of non-epithelial origin include sarcomas, brain tumors, and bone tumors.

In some embodiments, the patient herein is subjected to a diagnostic test e.g., prior to and/or during and/or after therapy. Generally, if a diagnostic test is performed, a sample may be obtained from a patient in need of therapy. Where the subject has cancer, the sample may be a tumor sample, or other biological sample, such as a biological fluid, including, without limitation, blood, urine, saliva, ascites fluid, or derivatives such as blood serum and blood plasma, and the like.

The biological sample herein may be a fixed sample, e.g. a formalin fixed, paraffin-embedded (FFPE) sample, or a frozen sample.

Various methods for determining expression of mRNA or protein include, but are not limited to, gene expression profiling, polymerase chain reaction (PCR) including quantitative real time PCR (qRT-PCR), microarray analysis, serial analysis of gene expression (SAGE), MassARRAY, Gene Expression Analysis by Massively Parallel Signature Sequencing (MPSS), proteomics, immunohistochemistry (IHC), etc. Preferably mRNA is quantified. Such mRNA analysis is preferably performed using the technique of polymerase chain reaction (PCR), or by microarray analysis. Where PCR is employed, a preferred form of PCR is quantitative real time PCR (qRT-PCR). In one embodiment, expression of one or more of the above noted genes is deemed positive expression if it is at the median or above, e.g. compared to other samples of the same tumor-type. The median expression level can be determined essentially contemporaneously with measuring gene expression, or may have been determined previously.

The steps of a representative protocol for profiling gene expression using fixed, paraffin-embedded tissues as the RNA source, including mRNA isolation, purification, primer extension and amplification are given in various published journal articles (for example: Godfrey et al. J. Molec. Diagnostics 2: 84-91 (2000); Specht et al, Am. J. Pathol. 158: 419-29 (2001)). Briefly, a representative process starts with cutting about 10 microgram thick sections of paraffin-embedded tumor tissue samples. The RNA is then extracted, and protein and DNA are removed. After analysis of the RNA concentration, RNA repair and/or amplification steps may be included, if necessary, and RNA is reverse transcribed using gene specific promoters followed by PCR. Finally, the data are
analyzed to identify the best treatment option(s) available to the patient on the basis of the characteristic gene expression pattern identified in the tumor sample examined.

Detection of gene or protein expression may be determined directly or indirectly.

One may determine expression or amplification of c-met and/or EGFR in the cancer (directly or indirectly). Various diagnostic/prognostic assays are available for this. In one embodiment, c-met and/or EGFR overexpression may be analyzed by IHC. Parafin embedded tissue sections from a tumor biopsy may be subjected to the IHC assay and accorded a c-met and/or EGFR protein staining intensity criteria as follows:

Score 0 no staining is observed or membrane staining is observed in less than 10% of tumor cells.

Score 1+ a faint/barely perceptible membrane staining is detected in more than 10% of the tumor cells. The cells are only stained in part of their membrane.

Score 2+ a weak to moderate complete membrane staining is observed in more than 10% of the tumor cells.

Score 3+ a moderate to strong complete membrane staining is observed in more than 10% of the tumor cells.

In some embodiments, those tumors with 0 or 1+ scores for c-met and/or EGFR overexpression assessment may be characterized as not overexpressing c-met and/or EGFR, whereas those tumors with 2+ or 3+ scores may be characterized as overexpressing c-met and/or EGFR.

In some embodiments, tumors overexpressing c-met and/or EGFR may be rated by immunohistochemical scores corresponding to the number of copies of c-met and/or EGFR molecules expressed per cell, and can be determined biochemically:

0 = 0-10,000 copies/cell,
1+ = at least about 200,000 copies/cell,
2+ = at least about 500,000 copies/cell,
3+ = at least about 2,000,000 copies/cell.

Alternatively, or additionally, FISH assays may be carried out on formalin-fixed, paraffin-embedded tumor tissue to determine the extent (if any) of c-met and/or EGFR amplification in the tumor.

C-met or EGFR activation may be determined directly (e.g., by phospho-ELISA testing, or other means of detecting phosphorylated receptor) or indirectly (e.g., by detection of activated downstream signaling pathway components, detection of receptor dimmers (e.g., homodimers, heterodimers), detection of gene expression profiles and the like.

Similarly, c-met or EGFR constitutive activation or presence of ligand-independent EGFR or c-met may be detected directly or indirectly (e.g., by detection of receptor mutations correlated with constitutive activity, by detection of receptor amplification correlated with constitutive activity and the like).
Methods for detection of nucleic acid mutations are well known in the art. Often, though not necessarily, a target nucleic acid in a sample is amplified to provide the desired amount of material for determination of whether a mutation is present. Amplification techniques are well known in the art. For example, the amplified product may or may not encompass all of the nucleic acid sequence encoding the protein of interest, so long as the amplified product comprises the particular amino acid/nucleic acid sequence position where the mutation is suspected to be.

In one example, presence of a mutation can be determined by contacting nucleic acid from a sample with a nucleic acid probe that is capable of specifically hybridizing to nucleic acid encoding a mutated nucleic acid, and detecting said hybridization. In one embodiment, the probe is detectably labeled, for example with a radioisotope ($^3$H, $^{32}$P, $^{33}$P etc.), a fluorescent agent (rhodamine, fluorescein etc.) or a chromogenic agent. In some embodiments, the probe is an antisense oligomer, for example PNA, morpholino-phosphorami dates, LNA or 2'-alkoxyalkoxy. The probe may be from about 8 nucleotides to about 100 nucleotides, or about 10 to about 75, or about 15 to about 50, or about 20 to about 30. In another aspect, nucleic acid probes of the invention are provided in a kit for identifying c-met mutations in a sample, said kit comprising an oligonucleotide that specifically hybridizes to or adjacent to a site of mutation in the nucleic acid encoding c-met. The kit may further comprise instructions for treating patients having tumors that contain c-met mutations with a c-met antagonist based on the result of a hybridization test using the kit.

Mutations can also be detected by comparing the electrophoretic mobility of an amplified nucleic acid to the electrophoretic mobility of corresponding nucleic acid encoding wild-type c-met. A difference in the mobility indicates the presence of a mutation in the amplified nucleic acid sequence. Electrophoretic mobility may be determined by any appropriate molecular separation technique, for example on a polyacrylamide gel.

Nucleic acids may also be analyzed for detection of mutations using Enzymatic Mutation Detection (EMD) (Del Tito et al, Clinical Chemistry 44:73 I-739, 1998). EMD uses the bacteriophage resolvase $T_4$ endonuclease VII, which scans along double-stranded DNA until it detects and cleaves structural distortions caused by base pair mismatches resulting from nucleic acid alterations such as point mutations, insertions and deletions. Detection of two short fragments formed by resolvase cleavage, for example by gel electrophoresis, indicates the presence of a mutation. Benefits of the EMD method are a single protocol to identify point mutations, deletions, and insertions assayed directly from amplification reactions, eliminating the need for sample purification, shortening the hybridization time, and increasing the signal-to-noise ratio. Mixed samples containing up to a 20-fold excess of normal nucleic acids and fragments up to 4 kb in size can be assayed. However, EMD scanning does not identify particular base changes that occur in mutation positive samples, therefore often requiring additional sequencing procedures to identify the specific mutation if necessary. CEL I enzyme can be used similarly to resolvase $T_4$ endonuclease VII, as demonstrated in US Pat. No. 5,869,245.
Another simple kit for detecting mutations is a reverse hybridization test strip similar to Haemochromatosis StripAssay™ (Viennalabs http://www.bamburghmarrsh.com/pdf/4228.pdf) for detection of multiple mutations in HFE, TFR2 and FPN1 genes causing Haemochromatosis. Such an assay is based on sequence specific hybridization following amplification by PCR. For single mutation assays, a microplate-based detection system may be applied, whereas for multi-mutation assays, test strips may be used as "macro-arrays". Kits may include ready-to-use reagents for sample prep, amplification and mutation detection. Multiplex amplification protocols provide convenience and allow testing of samples with very limited volumes. Using the straightforward StripAssay format, testing for twenty and more mutations may be completed in less than five hours without costly equipment. DNA is isolated from a sample and the target nucleic acid is amplified in vitro (e.g., by PCR) and biotin-labelled, generally in a single ("multiplex") amplification reaction. The amplification products are then selectively hybridized to oligonucleotide probes (wild-type and mutant specific) immobilized on a solid support such as a test strip in which the probes are immobilized as parallel lines or bands. Bound biotinylated amplicons are detected using streptavidin-alkaline phosphatase and color substrates. Such an assay can detect all or any subset of the mutations of the invention. With respect to a particular mutant probe band, one of three signaling patterns are possible: (i) a band only for wild-type probe which indicates normal nucleic acid sequence, (ii) bands for both wild-type and a mutant probe which indicates heterozygous genotype, and (iii) band only for the mutant probe which indicates homozygous mutant genotype. Accordingly, in one aspect, the invention provides a method of detecting mutations of the invention comprising isolating and/or amplifying a target c-met nucleic acid sequence from a sample, such that the amplification product comprises a ligand, contacting the amplification product with a probe which comprises a detectable binding partner to the ligand and the probe is capable of specifically hybridizing to a mutation of the invention, and then detecting the hybridization of said probe to said amplification product. In one embodiment, the ligand is biotin and the binding partner comprises avidin or streptavidin. In one embodiment, the binding partner comprises streptavidin-alkaline which is detectable with color substrates. In one embodiment, the probes are immobilized for example on a test strip wherein probes complementary to different mutations are separated from one another. Alternatively, the amplified nucleic acid is labelled with a radioisotope in which case the probe need not comprise a detectable label.

Alterations of a wild-type gene encompass all forms of mutations such as insertions, inversions, deletions, and/or point mutations. In one embodiment, the mutations are somatic. Somatic mutations are those which occur only in certain tissues, e.g., in the tumor tissue, and are not inherited in the germ line. Germ line mutations can be found in any of a body's tissues.

A sample comprising a target nucleic acid can be obtained by methods well known in the art, and that are appropriate for the particular type and location of the tumor. Tissue biopsy is often used to obtain a representative piece of tumor tissue. Alternatively, tumor cells can be obtained indirectly
in the form of tissues/fluids that are known or thought to contain the tumor cells of interest. For instance, samples of lung cancer lesions may be obtained by resection, bronchoscopy, fine needle aspiration, bronchial brushings, or from sputum, pleural fluid or blood. Mutant genes or gene products can be detected from tumor or from other body samples such as urine, sputum or serum. The same techniques discussed above for detection of mutant target genes or gene products in tumor samples can be applied to other body samples. Cancer cells are sloughed off from tumors and appear in such body samples. By screening such body samples, a simple early diagnosis can be achieved for diseases such as cancer. In addition, the progress of therapy can be monitored more easily by testing such body samples for mutant target genes or gene products.

Means for enriching a tissue preparation for tumor cells are known in the art. For example, the tissue may be isolated from paraffin or cryostat sections. Cancer cells may also be separated from normal cells by flow cytometry or laser capture microdissection. These, as well as other techniques for separating tumor from normal cells, are well known in the art. If the tumor tissue is highly contaminated with normal cells, detection of mutations may be more difficult, although techniques for minimizing contamination and/or false positive/negative results are known, some of which are described hereinbelow. For example, a sample may also be assessed for the presence of a biomarker (including a mutation) known to be associated with a tumor cell of interest but not a corresponding normal cell, or vice versa.

Detection of point mutations in target nucleic acids may be accomplished by molecular cloning of the target nucleic acids and sequencing the nucleic acids using techniques well known in the art. Alternatively, amplification techniques such as the polymerase chain reaction (PCR) can be used to amplify target nucleic acid sequences directly from a genomic DNA preparation from the tumor tissue. The nucleic acid sequence of the amplified sequences can then be determined and mutations identified therefrom. Amplification techniques are well known in the art, e.g., polymerase chain reaction as described in Saiki et al., Science 239:487, 1988; U.S. Pat. Nos. 4,683,203 and 4,683,195.

It should be noted that design and selection of appropriate primers are well established techniques in the art.

The ligase chain reaction, which is known in the art, can also be used to amplify target nucleic acid sequences. See, e.g., Wu et al., Genomics, Vol. 4, pp. 560-569 (1989). In addition, a technique known as allele specific PCR can also be used. See, e.g., Ruano and Kidd, Nucleic Acids Research, Vol. 17, p. 8392, 1989. According to this technique, primers are used which hybridize at their 3'ends to a particular target nucleic acid mutation. If the particular mutation is not present, an amplification product is not observed. Amplification Refractory Mutation System (ARMS) can also be used, as disclosed in European Patent Application Publication No. 0332435, and in Newton et al., Nucleic Acids Research, Vol. 17, p.7, 1989. Insertions and deletions of genes can also be detected by cloning, sequencing and amplification. In addition, restriction fragment length polymorphism (RFLP) probes
for the gene or surrounding marker genes can be used to score alteration of an allele or an insertion in
a polymorphic fragment. Single stranded conformation polymorphism (SSCP) analysis can also be
insertions and deletions as known in the art can also be used.

Alteration of wild-type genes can also be detected on the basis of the alteration of a wild-type
expression product of the gene. Such expression products include both mRNA as well as the protein
product. Point mutations may be detected by amplifying and sequencing the mRNA or via molecular
cloning of cDNA made from the mRNA. The sequence of the cloned cDNA can be determined using
DNA sequencing techniques which are well known in the art. The cDNA can also be sequenced via
the polymerase chain reaction (PCR).

Mismatches are hybridized nucleic acid duplexes which are not 100% complementary. The
lack of total complementarity may be due to deletions, insertions, inversions, substitutions or
frameshift mutations. Mismatch detection can be used to detect point mutations in a target nucleic
acid. While these techniques can be less sensitive than sequencing, they are simpler to perform on a
large number of tissue samples. An example of a mismatch cleavage technique is the RNase
protection method, which is described in detail in Winter et al., Proc. Natl. Acad. Sci. USA, Vol. 82,
invention may involve the use of a labeled riboprobe which is complementary to the human wild-type
target nucleic acid. The riboprobe and target nucleic acid derived from the tissue sample are annealed
(hybridized) together and subsequently digested with the enzyme RNase A which is able to detect
some mismatches in a duplex RNA structure. If a mismatch is detected by RNase A, it cleaves at the
site of the mismatch. Thus, when the annealed RNA preparation is separated on an electrophoretic gel
matrix, if a mismatch has been detected and cleaved by RNase A, an RNA product will be seen which
is smaller than the full-length duplex RNA for the riboprobe and the mRNA or DNA. The riboprobe
need not be the full length of the target nucleic acid mRNA or gene, but can a portion of the target
nucleic acid, provided it encompasses the position suspected of being mutated. If the riboprobe
comprises only a segment of the target nucleic acid mRNA or gene, it may be desirable to use a
number of these probes to screen the whole target nucleic acid sequence for mismatches if desired.

In a similar manner, DNA probes can be used to detect mismatches, for example through
enzymatic or chemical cleavage. See, e.g., Cotton et al., Proc. Natl. Acad. Sci. USA, Vol. 85, 4397,
can be detected by shifts in the electrophoretic mobility of mismatched duplexes relative to matched
duplexes. See, e.g., Cariello, Human Genetics, Vol. 42, p. 726, 1988. With either riboprobes or DNA
probes, the target nucleic acid mRNA or DNA which might contain a mutation can be amplified
before hybridization. Changes in target nucleic acid DNA can also be detected using Southern
hybridization, especially if the changes are gross rearrangements, such as deletions and insertions.
Target nucleic acid DNA sequences which have been amplified may also be screened using allele-specific probes. These probes are nucleic acid oligomers, each of which contains a region of the target nucleic acid gene harboring a known mutation. For example, one oligomer may be about 30 nucleotides in length, corresponding to a portion of the target gene sequence. By use of a battery of such allele-specific probes, target nucleic acid amplification products can be screened to identify the presence of a previously identified mutation in the target gene. Hybridization of allele-specific probes with amplified target nucleic acid sequences can be performed, for example, on a nylon filter. Hybridization to a particular probe under stringent hybridization conditions indicates the presence of the same mutation in the tumor tissue as in the allele-specific probe.

Alteration of wild-type target genes can also be detected by screening for alteration of the corresponding wild-type protein. For example, monoclonal antibodies immunoreactive with a target gene product can be used to screen a tissue, for example an antibody that is known to bind to a particular mutated position of the gene product (protein). For example, an antibody that is used may be one that binds to a deleted exon (e.g., exon 14) or that binds to a conformational epitope comprising a deleted portion of the target protein. Lack of cognate antigen would indicate a mutation. Antibodies specific for products of mutant alleles could also be used to detect mutant gene product. Antibodies may be identified from phage display libraries. Such immunological assays can be done in any convenient format known in the art. These include Western blots, immunohistochemical assays and ELISA assays. Any means for detecting an altered protein can be used to detect alteration of wild-type target genes.

Primer pairs are useful for determination of the nucleotide sequence of a target nucleic acid using nucleic acid amplification techniques such as the polymerase chain reaction. The pairs of single stranded DNA primers can be annealed to sequences within or surrounding the target nucleic acid sequence in order to prime amplification of the target sequence. Allele-specific primers can also be used. Such primers anneal only to particular mutant target sequence, and thus will only amplify a product in the presence of the mutant target sequence as a template. In order to facilitate subsequent cloning of amplified sequences, primers may have restriction enzyme site sequences appended to their ends. Such enzymes and sites are well known in the art. The primers themselves can be synthesized using techniques which are well known in the art. Generally, the primers can be made using oligonucleotide synthesizing machines which are commercially available. Design of particular primers is well within the skill of the art.

Nucleic acid probes are useful for a number of purposes. They can be used in Southern hybridization to genomic DNA and in the RNase protection method for detecting point mutations already discussed above. The probes can be used to detect target nucleic acid amplification products. They may also be used to detect mismatches with the wild type gene or mRNA using other techniques. Mismatches can be detected using either enzymes (e.g., S1 nuclease), chemicals (e.g., hydroxylamine or osmium tetroxide and piperidine), or changes in electrophoretic mobility of
mismatched hybrids as compared to totally matched hybrids. These techniques are known in the art. See Novack et al, Proc. Natl. Acad. Sci. USA, Vol. 83, p. 586, 1986. Generally, the probes are complementary to sequences outside of the kinase domain. An entire battery of nucleic acid probes may be used to compose a kit for detecting mutations in target nucleic acids. The kit allows for hybridization to a large region of a target sequence of interest. The probes may overlap with each other or be contiguous.

If a riboprobe is used to detect mismatches with mRNA, it is generally complementary to the mRNA of the target gene. The riboprobe thus is an antisense probe in that it does not code for the corresponding gene product because it is complementary to the sense strand. The riboprobe generally will be labeled with a radioactive, colorimetric, or fluorometric material, which can be accomplished by any means known in the art. If the riboprobe is used to detect mismatches with DNA it can be of either polarity, sense or anti-sense. Similarly, DNA probes also may be used to detect mismatches.

In some instances, the cancer does or does not overexpress c-met receptor and/or EGFR. Receptor overexpression may be determined in a diagnostic or prognostic assay by evaluating increased levels of the receptor protein present on the surface of a cell (e.g. via an immunohistochemistry assay; IHC). Alternatively, or additionally, one may measure levels of receptor-encoding nucleic acid in the cell, e.g. via fluorescent in situ hybridization (FISH; see WO98/45479 published October, 1998), southern blotting, or polymerase chain reaction (PCR) techniques, such as real time quantitative PCR (RT-PCR). Aside from the above assays, various in vivo assays are available to the skilled practitioner. For example, one may expose cells within the body of the patient to an antibody which is optionally labeled with a detectable label, e.g. a radioactive isotope, and binding of the antibody to cells in the patient can be evaluated, e.g. by external scanning for radioactivity or by analyzing a biopsy taken from a patient previously exposed to the antibody.

**Chemotherapeutic Agents**

The combination therapy of the invention can further comprise one or more chemotherapeutic agent(s). The combined administration includes coadministration or concurrent administration, using separate formulations or a single pharmaceutical formulation, and consecutive administration in either order, wherein preferably there is a time period while both (or all) active agents simultaneously exert their biological activities.

The chemotherapeutic agent, if administered, is usually administered at dosages known therefor, or optionally lowered due to combined action of the drugs or negative side effects attributable to administration of the antimetabolite chemotherapeutic agent. Preparation and dosing schedules for such chemotherapeutic agents may be used according to manufacturers' instructions or as determined empirically by the skilled practitioner.

Various chemotherapeutic agents that can be combined are disclosed above. Preferred chemotherapeutic agents to be combined are selected from the group consisting of a taxoid (including
docetaxel and paclitaxel), vinca (such as vinorelbine or vinblastine), platinum compound (such as carboplatin or cisplatin), aromatase inhibitor (such as letrozole, anastrazole, or exemestane), anti-estrogen (e.g. fulvestrant or tamoxifen), etoposide, thiotepa, cyclophosphamide, methotrexate, liposomal doxorubicin, pegylated liposomal doxorubicin, capecitabine, gemcitabine, COX-2 inhibitor (for instance, celecoxib), or proteosome inhibitor (e.g. PS342).

Formulations, Dosages and Administrations

The therapeutic agents used in the invention will be formulated, dosed, and administered in a fashion consistent with good medical practice. Factors for consideration in this context include the particular disorder being treated, the particular subject being treated, the clinical condition of the individual patient, the cause of the disorder, the site of delivery of the agent, the method of administration, the scheduling of administration, the drug-drug interaction of the agents to be combined, and other factors known to medical practitioners.

Therapeutic formulations are prepared using standard methods known in the art by mixing the active ingredient having the desired degree of purity with optional physiologically acceptable carriers, excipients or stabilizers (Remington's Pharmaceutical Sciences (20th edition), ed. A. Gennaro, 2000, Lippincott, Williams & Wilkins, Philadelphia, PA). Acceptable carriers, include saline, or buffers such as phosphate, citrate and other organic acids; antioxidants including ascorbic acid; low molecular weight (less than about 10 residues) polypeptides; proteins, such as serum albumin, gelatin or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids such as glycine, glutamine, asparagines, arginine or lysine; monosaccharides, disaccharides, and other carbohydrates including glucose, mannose, or dextrins; chelating agents such as EDTA; sugar alcohols such as mannitol or sorbitol; salt-forming counterions such as sodium; and/or nonionic surfactants such as TWEEN™, PLURONICS™, or PEG.

Optionally, but preferably, the formulation contains a pharmaceutically acceptable salt, preferably sodium chloride, and preferably at about physiological concentrations. Optionally, the formulations of the invention can contain a pharmaceutically acceptable preservative. In some embodiments the preservative concentration ranges from 0.1 to 2.0%, typically v/v. Suitable preservatives include those known in the pharmaceutical arts. Benzyl alcohol, phenol, m-cresol, methylparaben, and propylparaben are preferred preservatives. Optionally, the formulations of the invention can include a pharmaceutically acceptable surfactant at a concentration of 0.005 to 0.02%.

The formulation herein may also contain more than one active compound as necessary for the particular indication being treated, preferably those with complementary activities that do not adversely affect each other. Such molecules are suitably present in combination in amounts that are effective for the purpose intended.

The active ingredients may also be entrapped in microcapsule prepared, for example, by coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatin-microcapsule and poly-(methylmethacrylate) microcapsule, respectively, in colloidal drug
delivery systems (for example, liposomes, albumin microspheres, microemulsions, nano-particles and nanocapsules) or in macroemulsions. Such techniques are disclosed in Remington's Pharmaceutical Sciences, *supra*.

Sustained-release preparations may be prepared. Suitable examples of sustained-release preparations include semipermeable matrices of solid hydrophobic polymers containing the antibody, which matrices are in the form of shaped articles, e.g., films, or microcapsule. Examples of sustained-release matrices include polyesters, hydrogels (for example, poly(2-hydroxyethyl-methacrylate), or poly(vinylalcohol)), polylactides (U.S. Pat. No. 3,773,919), copolymers of L-glutamic acid and γ ethyl-L-glutamate, non-degradable ethylene-vinyl acetate, degradable lactic acid-glycolic acid copolymers such as the LUPRON DEPOT™ (injectable microspheres composed of lactic acid-glycolic acid copolymer and leuprolide acetate), and poly-D(-)-3-hydroxybutyric acid. While polymers such as ethylene-vinyl acetate and lactic acid-glycolic acid enable release of molecules for over 100 days, certain hydrogels release proteins for shorter time periods. When encapsulated antibodies remain in the body for a long time, they may denature or aggregate as a result of exposure to moisture at 37°C, resulting in a loss of biological activity and possible changes in immunogenicity. Rational strategies can be devised for stabilization depending on the mechanism involved. For example, if the aggregation mechanism is discovered to be intermolecular S-S bond formation through thio-disulfide interchange, stabilization may be achieved by modifying sulfhydryl residues, lyophilizing from acidic solutions, controlling moisture content, using appropriate additives, and developing specific polymer matrix compositions.

The therapeutic agents of the invention are administered to a human patient, in accord with known methods, such as intravenous administration as a bolus or by continuous infusion over a period of time, by intramuscular, intraperitoneal, intracerebrospinal, subcutaneous, intra-articular, intrasynovial, intrathecal, oral, topical, or inhalation routes. In the case of VEGF antagonists, local administration is particularly desired if extensive side effects or toxicity is associated with VEGF antagonism. An *ex vivo* strategy can also be used for therapeutic applications. *Ex vivo* strategies involve transfecting or transducing cells obtained from the subject with a polynucleotide encoding a c-met or EGFR antagonist. The transected or transduced cells are then returned to the subject. The cells can be any of a wide range of types including, without limitation, hemopoietic cells (e.g., bone marrow cells, macrophages, monocytes, dendritic cells, T cells, or B cells), fibroblasts, epithelial cells, endothelial cells, keratinocytes, or muscle cells.

For example, if the c-met or EGFR antagonist is an antibody, the antibody is administered by any suitable means, including parenteral, subcutaneous, intraperitoneal, intrapulmonary, and intranasal, and, if desired for local immunosuppressive treatment, intralesional administration. Parenteral infusions include intramuscular, intravenous, intraarterial, intraperitoneal, or subcutaneous administration. In addition, the antibody is suitably administered by pulse infusion, particularly with declining doses of the antibody. Preferably the dosing is given by injections, most preferably
intravenous or subcutaneous injections, depending in part on whether the administration is brief or chronic.

In another example, the c-met or EGFR antagonist compound is administered locally, e.g., by direct injections, when the disorder or location of the tumor permits, and the injections can be repeated periodically. The c-met or EGFR antagonist can also be delivered systemically to the subject or directly to the tumor cells, e.g., to a tumor or a tumor bed following surgical excision of the tumor, in order to prevent or reduce local recurrence or metastasis.

Administration of the therapeutic agents in combination typically is carried out over a defined time period (usually minutes, hours, days or weeks depending upon the combination selected). Combination therapy is intended to embrace administration of these therapeutic agents in a sequential manner, that is, wherein each therapeutic agent is administered at a different time, as well as administration of these therapeutic agents, or at least two of the therapeutic agents, in a substantially simultaneous manner.

The therapeutic agent can be administered by the same route or by different routes. For example, the EGFR or c-met antagonist in the combination may be administered by intravenous injection while the protein kinase inhibitor in the combination may be administered orally. Alternatively, for example, both of the therapeutic agents may be administered orally, or both therapeutic agents may be administered by intravenous injection, depending on the specific therapeutic agents. The sequence in which the therapeutic agents are administered also varies depending on the specific agents.

Depending on the type and severity of the disease, about 1 µg/kg to 100 mg/kg (e.g., 0.1-20 mg/kg) of each therapeutic agent is an initial candidate dosage for administration to the patient, whether, for example, by one or more separate administrations, or by continuous infusion. A typical daily dosage might range from about 1 µg/kg to about 100 mg/kg or more, depending on the factors mentioned above. For repeated administrations over several days or longer, depending on the condition, the treatment is sustained until the cancer is treated, as measured by the methods described above. However, other dosage regimens may be useful. In one example, if the cmet or EGFR antagonist is an antibody, the antibody of the invention is administered every two to three weeks, at a dose ranging from about 5 mg/kg to about 15 mg/kg. If the c-met or EGFR antagonist is an oral small molecule compound, the drug is administered daily at a dose ranging from about 25 mg/kg to about 50 mg/kg. Moreover, the oral compound of the invention can be administered either under a traditional high-dose intermittent regimen, or using lower and more frequent doses without scheduled breaks (referred to as "metronomic therapy"). When an intermittent regimen is used, for example, the drug can be given daily for two to three weeks followed by a one week break; or daily for four weeks followed by a two week break, depending on the daily dose and particular indication. The progress of the therapy of the invention is easily monitored by conventional techniques and assays.
The present application contemplates administration of the met and/or EGFR antagonist by gene therapy. See, for example, WO96/07321 published March 14, 1996 concerning the use of gene therapy to generate intracellular antibodies.

There are two major approaches to getting the nucleic acid (optionally contained in a vector) into the patient's cells; in vivo and ex vivo. For in vivo delivery the nucleic acid is injected directly into the patient, usually at the site where the antibody is required. For ex vivo treatment, the patient's cells are removed, the nucleic acid is introduced into these isolated cells and the modified cells are administered to the patient either directly or, for example, encapsulated within porous membranes which are implanted into the patient (see, e.g. U.S. Patent Nos. 4,892,538 and 5,283,187). There are a variety of techniques available for introducing nucleic acids into viable cells. The techniques vary depending upon whether the nucleic acid is transferred into cultured cells in vitro, or in vivo in the cells of the intended host. Techniques suitable for the transfer of nucleic acid into mammalian cells in vitro include the use of liposomes, electroporation, microinjection, cell fusion, DEAE-dextran, the calcium phosphate precipitation method, etc. A commonly used vector for ex vivo delivery of the gene is a retrovirus.

The currently preferred in vivo nucleic acid transfer techniques include transfection with viral vectors (such as adenovirus, Herpes simplex I virus, or adeno-associated virus) and lipid-based systems (useful lipids for lipid-mediated transfer of the gene are DOTMA, DOPE and DC-Choi, for example). In some situations it is desirable to provide the nucleic acid source with an agent that targets the target cells, such as an antibody specific for a cell surface membrane protein or the target cell, a ligand for a receptor on the target cell, etc. Where liposomes are employed, proteins which bind to a cell surface membrane protein associated with endocytosis may be used for targeting and/or to facilitate uptake, e.g. capsid proteins or fragments thereof tropic for a particular cell type, antibodies for proteins which undergo internalization in cycling, and proteins that target intracellular localization and enhance intracellular half-life. The technique of receptor-mediated endocytosis is described, for example, by Wu et al, J. Biol. Chem. 262:4429-4432 (1987); and Wagner et al, Proc. Natl. Acad. Sci. USA 87:3410-3414 (1990). For review of the currently known gene marking and gene therapy protocols see Anderson et al, Science 256:808-813 (1992). See also WO 93/25673 and the references cited therein.

The following are examples of the methods and compositions of the invention. It is understood that various other embodiments may be practiced, given the general description provided above.

**EXAMPLES**

**Example 1:** Analysis of c-met and EGFR expression in NSCLC cell lines and tumor samples.

**Materials and methods**

Microarray studies. Basal gene expression analysis of NSCLC cell lines and primary tumors was carried out using RNA extracted from sub-confluent cell cultures or frozen tumor lysates on the Affymetrix (Santa Clara, CA) microarray platform (HGU133Plus_2.0 chips). Preparation of
complementary RNA, array hybridizations, and subsequent data analysis were carried out using manufacturer protocols, essentially as described in Hoffman EP et al., Nat Rev Genet 5:229-37 (2004).

To evaluate correlation of c-met expression with expression of other receptor tyrosine kinases (RTKs) expressed in NSCLC specimens, a variation filter was used to exclude genes with minimal variation across the samples being analyzed. Genes with minimal expression (those for which the absolute variation (max-min) across samples was < 1000) were excluded from further analysis. In addition, a single probe was selected to represent a gene. Spearman rank correlation coefficients (p) were determined for each gene against METmRNA (probe ID, 203510_at) or c-met protein (IHC).

Quantitative PCR. EGFR and AffiTmRNA expression levels were assessed by quantitative RT-PCR using standard Taqman techniques. Transcript levels were normalized to the housekeeping gene ribosomal protein L19 (RPL19) and results were expressed as either normalized expression values (2^-ΔCt) or normalized expression relative to a pooled tissue source (2^-ΔΔCt). The following primer/probe sets were utilized:

RPL19: forward primer, 5'-ACCCCAATGAGACCAATGAAATC-S ' (SEQ ID NO:26), reverse primer, 5'-ATCTTTGATGAGCTTCCGGATCT-S ' (SEQ IDNO:27), probe, 5'(VIC)- AATGCCAACTCGTCCAG-(MGBNFQ)-3' (SEQ ID NO:28);
MET: forward primer, 5'- CATTAAAGGACCTACCATTAGCTAAT-3 ' (SEQ ID NO:29), reverse primer, 5'- CCTGATCGAGAAAACCACAACCT-3 ' (SEQ ID NO:30), probe, 5'(FAM)- CATGAAGCGACCCTCTGATGTCCCA-(BHQ-1)-3' (SEQ ID NO:31).

Primer/probe sets for EGFR were purchased from Applied Biosystems (cat # 4331182, HsO0193306; Foster City, CA).

Immunohistochemistry (IHC). Formalin fixed and paraffin-embedded specimens were sectioned at 5 micron thickness onto slides. After deparaffinization and rehydration, sections were processed for c-Met and EGFR IHC analysis. EGFR IHC was performed with the EGFR pharmDx™ Kit (Dako, Glostrup, Denmark) according to the Manufacturer's instructions. For c-met immunohistochemistry (IHC), antigen retrieval was performed using preheated Target Retrieval buffer (Dako, Glostrup, Denmark) at 99°C for 40 minutes for the c-met IHC. Endogenous peroxidase activity was quenched with KPL Blocking Solution (KPL, Gaithersburg, MD) at room temperature for 4 minutes. Endogenous avidin/biotin was blocked with Vector Avidin Biotin Blocking Kit (Vector Laboratories, Burlingame, CA). Subsequently, sections were incubated with 10 µg/ml mouse anti-c-met (clone DL-21) monoclonal antibody (Upstate Biotechnology Inc. Lake Placid, NY) in blocking serum for 60 minutes at room temperature, and followed by incubation with biotinylated secondary horse anti-mouse antibody for 30 minutes. Vectastain ABC Elite Reagent (Vector Laboratory, Burlingame, CA) with Metal Enhanced DAB (Pierce Biotechnology, Inc. Rockford, IL) was used to develop the slides. The levels of expression were defined as negative (-), weak (+), moderate (++) or
strong (+++). Cell lines or tumor specimen that contain more than 10% tumor cells with weak, moderate, or strong staining were considered positive.

Cell Culture and tumor samples. Cell lines were obtained from the American Type Culture Collection, the NCI Division of Cancer Treatment and Diagnosis, and the Japanese Health Sciences Resources depositories as shown in Table 1. All cell lines were maintained in RPMI 1640 supplemented with 10% FBS (Sigma, St. Louis, MO), and 2 mM L-glutamine. Tumor samples were obtained from University of Michigan, Cybrdio, Cooperative Human Tissue Network and Integrated Laboratory services.

METmRNA expression correlates with EGFR niRNA expression in NSCLC cell lines.

To evaluate whether the expression of c-met is correlated with the expression of EGFR and other receptor tyrosine kinases (RTKs) in NSCLC cell lines, spearman rank correlation coefficients were determined from microarray-based gene expression data generated from the 50 NSCLC cell lines shown in Table 1. EGFR and METmRNA levels were positively correlated in cell lines (p=0.54, p<0.0001) and EGFR expression was highly correlated with MET expression (Table 2).

**MET mRNA expression correlates with EGFR miRNA expression in NSCLC tumor samples.**

To evaluate whether c-met mRNA expression is correlated with expression of EGFR and other receptor tyrosine kinases (RTKs) in the NSCLC cell lines shown in Table 1, spearman rank correlation coefficients were determined from microarray-based gene expression data generated from 78 NSCLC tumors. Expression of *EGFR* mRNA and METmRNA was positively correlated in NSCLC tumors (p=0.26, p=0.02) (Table 4).
Table 4. Correlation of RTKmRNA expression with MET mRNA expression in NSCLC tumors.

Coexpression of EGFR and MET in NSCLC cell lines and primary tumors.

To evaluate whether c-met and EGFR are coexpressed in NSCLC cell lines and primary tumor samples, expression of EGFR and MET mRNA was determined by quantitative RT-PCR in a panel of NSCLC cell lines (as indicated in Table 1) or frozen primary NSCLC tumor lysates. EGFR and MET mRNA levels were positively correlated in cell lines (p=0.59, p<0.0001) (Figure 1, left panel) and primary NSCLC specimens (p=0.48, p=0.0003) (Figure 1, right panel). These data demonstrate that there is an overlap in the expression of MET and EGFR in NSCLC cell lines and primary tumor samples.

Confirmation of EGFR and MET coexpression by IHC in NSCLC cell lines and primary tumors.

Forty-seven non-small cell lung cancer (NSCLC) cell lines (as indicated in Table 1) and one hundred thirty eight primary NSCLC samples (Genentech collection) were examined for their c-met and EGFR IHC expression by IHC. The levels of expression were scored as negative (-), weak (+), moderate (++) or strong (+++), and a cell line or tumor specimen that contained more than 10% tumor cells with weak, moderate, or strong staining was scored as positive.

79% (37/47) of cell lines and 68% (94/138) of NSCLC tumors stained positive for EGFR (Table 5). The EGFR positive samples (79% of cell lines and 68% of primary tumors) were further stratified based on their c-met expression levels (Table 5). The EGFR positive cell lines exhibited weak (22%), moderate (57%) and strong (19%) c-met expression, and the EGFR-positive primary tumor samples were only weakly or moderately positive. The adenocarcinoma subtype were more commonly positive for c-met staining than the squamous cell subtype (70% versus 40%), with more cases of moderate staining (30% versus 7%). These data demonstrate a significant overlap between c-met and EGFR expression in NSCLC cell lines and tumor samples, particularly in the adenocarcinoma tumor subtype.

Example 2: Reduction of c-met protein expression in NSCLC cells increases ligand-induced activation of EGFR, Her2 and Her3.

**Materials and methods**

Retroviral shRNA constructs. Oligonucleotides coding shRNA sequences against c-met (5'-GATCCCCGAAACGAATCAGACATATTCAAGAGATGTCAGTGATTCTGTCTTTT TTGGAAA-3' (SEQ ID NO: 32) (shMet 3) and 5'-GATCCCCAACTGATGCTGGATGATTCAAGAGATCATCCAGCATACAGTTGCTTTT TCTTATTGAAAA (SEQ ID NO: 33) (shMet 4)) were cloned into BglII/HindIII sites of the pShuttle-H1 vector downstream of the H1 promoter (David Davis, GNE). BOLD text signifies the target hybridizing sequence. These constructs were recombined with the retroviral pHUSH-GW vector (Gray D et al. BMC Biotechnology. 2007; 7:61) using Clonase II enzyme (Invitrogen), generating a construct in which the shRNA expression is under control of an inducible promoter. Treatment with the tetracycline analog doxycycline results in shRNA expression. The shGFP2 control retroviral construct containing a shRNA directed against GFP (Hoeflich et al. Cancer Res. 2006) 66(2):999-1006) was provided by David Davis, Genentech, Inc. shGFP2 contains the following oligonucleotide:

(EGFP) shRNA

(sense) 5'- GTTGGAAA-3' (SEQ ID NO:34).

Cell Culture. GP-293 packaging cells (Clontech) were maintained in HGDMEM (GNE) supplemented with 10% Tet-Free FBS (Clontech), 2mM L-Glutamine (GNE), and 100U/ml penicillin and 100U/ml streptomycin (Gibco). H441 cells (ATCC No. HTB-174) were maintained in 50:50 media (DMEM:F12, MediaTech) supplemented with 10% Tet-Free FBS (Clontech), 2mM L-Glutamine (GNE), and 100U/ml penicillin and 100U/ml streptomycin (Gibco). EBC-I cells (Japanese Health Sciences Resources; see Cancer Res. (2005) 65(16):7276-82) were maintained in RPMI 1640 (GNE) supplemented with 10% Tet-Free FBS (Clontech), 2mM L-Glutamine (GNE), and 100U/ml penicillin and 100U/ml streptomycin (Gibco). Cells were maintained at 37°C with 5% CO2.

Development of recombinant retroviral and stable lines. GP-293 packaging cells were cotransfected using FuGene 6 (Roche) and CalPhos Mammalian Transfection kit (Clontech) with pHSV-G (Clontech) and the above recombinant retroviral constructs. Media containing the recombinant virus was then added to EBC-I and H441 cells and cells were selected in Puromycin (Clontech). Cells stably expressing retroviral constructs were then autocloned via FACS into 96 well plates.

Western blot. To resolve proteins, 20 ug of whole cell lysate was run on 4-12% Bis-Tris NuPAGE gel with MOPS buffer (Invitrogen). Gels were equilibrated in 2X NUPAGE transfer buffer with anti-oxidant buffer then transferred to 0.2 um PVDF membrane by iBlot. Membranes were
blocked in TBST (10mM TRIS, pH 8.0, 150mM NaCl, 0.1% Tween 20) containing 5% BSA for one hour at room temperature then incubated overnight in primary antibody diluted in blocking buffer at 4°C. Membranes were washed with TBST then incubated with the HRP-conjugated secondary antibody (GE Healthcare) in TBST with 5% nonfat milk for one hour at room temperature. Antibodies were detected by chemiluminescence (GE Healthcare, ECL Plus).

**Screening of stable cell lines.** Clones stably transduced with retroviral constructs were grown in the appropriate media +/- 1μg/ml doxycycline (Clontech) to induce expression of the shRNA, and screened via western blots for c-met knockdown using anti-c-met C-12 antibody (Santa Cruz Biotech). Phospho-c-met was blotted for using anti-Phospho-c-met Y1003 (Biosource) and anti-Phospho-c-met Y1234/1234 (Cell Signaling) antibodies. As a control, actin was blotted for using anti-Actin 1-19 antibody (Santa Cruz Biotech). EBC Clone 3.15 and EBC clone 4.12 showed strong reduction of met expression and phospho c-met levels, H441 Clone 3.11 and H441 Clone 3.1 showed intermediate reduction of c-met expression and phospho-met expression, and EBC clone 4.5 showed a smaller reduction of c-met and phospho-c-met expression.

Cell lines EBC clone 4.5, EBC clone 4.12 contained construct shMet4 and cell lines H441 Clone 3.1, H441 Clone 3.11, and EBC Clone 3.15 contained construct shMet 3.

**Ligand response experiments.** Cells passaged with/without doxycycline for 48 hours (EBC shMet) or 6 days (H441 shMet) were plated at 1x10⁶ cells/well in a 6-well dish with/without Dox (0.1 μg/ml) in 10% FBS-RPMI then incubated overnight at 37°C. Cells were rinsed with PBS, and media was changed to 0.5% BSA-RPMI (with/without doxycycline) to serum starve cells for 2 hours at 37°C. Media containing ligand (20 nM TGFa or 2nM HRG) was added to wells and incubated for 20 minutes at 37°C. Wells were rinsed with cold TBS then lysed with TBS, 1% NP-40, Complete protease inhibitor cocktail (Roche) and phosphatase inhibitor cocktails 1 and 2 (Sigma). The monolayer and supernatant was scraped from the well and transferred to microfuge tubes where the lysate was incubated on ice for 10-30 minutes. Cell debris was pelleted by microfuge, and the supernatant was transferred to a fresh tube. Protein concentration was quantified by BCA assay (Pierce), and lysates were stored at -20°C until thawed for electrophoresis. 20ug (EBC) or 15ug (H441) of whole cell lysate were run on gels and blotted for phospho-c-met (YY1234/35, 3126 from Cell Signaling Technology), total c-met (C12, sc-10 from San Cruz Biotechnology), b-actin (1-19, sc-1616 from Santa Cruz Biotechnology), phospho-EGFR (Y1 173, 04-341 from Upstate), total EGFR (MI-12-1, from MBL), phospho-Her2 (YY1 121/22, 2243 from Cell Signaling Technology), total Her3 (C18, sc-284, from San Cruz Biotechnology), phospho-Her3 (Y1289, 4791, from Cell Signaling Technology), or total Her3 (Cl 7, sc-285, from Santa Cruz Biotechnology) as described above.

**Results**

Retroviruses carrying tetracycline-inducible short-hairpin RNA (shRNA) that target c-met were used to generate stable NSCLC cell line clones that could be induced to express shRNAs to knockdown c-met expression. To examine the effect of c-met knockdown on expression and
phosphorylation of EGFR family members in NSCLC cell line EBCl, EBCl shMet 4.12 cells containing an inducible shRNA directed against met or control shRNA directed against GFP were grown in control media or media containing 0.1ug/ml Dox for 48 hours. After serum-starvation for two hours, cells were untreated or treated with TGFα or Heregulin b1 for 20 minutes. Whole cell lysates were evaluated for expression of total and phospho-proteins as indicated.

Dox-treated EBCl cells in which c-met protein expression was knocked-down using shRNA (Figure 2; EBCShMet 4.12, Dox, left panel), but not Dox-treated control EBCl cells (Figure 2; shGFP2, right panel) showed increased pEGFR and pHer2 in response to TGFα treatment and increased pHer3 in response to Heregulin treatment, as well as increased pAKT with either TGFα or Heregulin treatment. The Dox-treated EBC shMet 4.12 cells (no ligand stimulation) showed increased total Her2 and total Her3, and decreased pEGFR and pHer3. EBCl cells did not show robust induction of pEGFR, pHer2, pHer3, or pAKT in response to TGFα or Heregulin treatment in the absence of c-met knock-down.

To examine the effect of c-met knockdown on expression and phosphorylation of EGFR family members in another NSCLC cell line, NSCLC H441 cells containing an inducible shRNA directed against met or control shRNA directed against GFP were grown in control media or media containing 0.1ug/ml Dox for 48 hours. After serum-starvation for 2 hours, cells were untreated or treated with TGFα or Heregulin b1 for 20 minutes. Whole cell lysates were evaluated for expression of total and phospho-proteins as indicated.

H441 cells in which c-met was knocked-down using shRNA (Figure 3; Dox-treated shMet 3.1, left panel and Dox-treated shMet 3.11 middle panel), but not Dox-treated control H441 cells (Figure 3; shGFP1, right panel) showed enhanced pHer2 and pHer3 in response to Heregulin treatment. The Dox treated shMet 3.1 and shMet 3.11 cells also show increased total Her3 and decreased pEGFR. Unlike EBCl cells, H441 cells have a slight response to TGFα (pEGFR) and Heregulin (pHer2 and pHer3) without c-met knock-down. EBCl cells have higher c-met levels than H441 cells.

These experiments demonstrated that reduction of c-met expression in NSCLC cell lines leads to decreased basal activation of EGFR (pEGFR) and increased ligand-induced activation of Her 2 and Her3, suggesting that Met inhibition increases sensitivity to ligands of the EGF family.

Example 3: The combination of met knockdown and treatment with EGFR inhibitor erlotinib significantly inhibited tumor growth in a xenograft model.

To test whether EGFR plays a role in maintaining tumor survival in cell in which c-met function is partially inhibited, EBC-I shMet-4.5 tumor bearing animals were treated with combinations of erlotinib (Tarceva™) and Dox.

**Materials and methods**

Test material. Erlotinib (Tarceva™) was provided by OSI Pharmaceuticals to the Formulations Department at Genentech and was weighed out along with a sufficient amount of
vehicle (methylcellulose tween (MCT)). Materials were stored in a refrigerator set to maintain a
temperature range of 4°C to 8°C. Anti-c-met monovalent monoclonal antibody MetMAb
(rhuOA5D5v2) (WO2007/063816) was provided by the Antibody Engineering Department at
Genentech, Inc., in a clear liquid form. The EBC-I cell line was obtained from Japanese Collection of
Research Bioresources (JCRB).

Species. Forty nude mice (nu/nu) were obtained from Charles River Laboratories (CRL) and
were acclimatized for at least one week prior to being put on study. Animals were housed in
ventilated caging systems in rooms with filters supplying High-Efficiency Particulate Air (HEPA).
Only animals that appeared to be healthy and were free of obvious abnormalities were used for the
study.

Study design. EBC-I cells were cultured in growth media that consisted of RPMI 1640
media (Invitrogen), 2 mM L-glutamine, and 10% fetal bovine serum. To prepare cells for inoculation
into mice, cells were trypsinized, washed with ten milliliters of sterile IX phosphate buffered saline
(PBS). A subset of cells was counted by trypan blue exclusion and the remainder of cells was
resuspended in 100 µl of sterile IX PBS to a concentration of 5 x 10^7 cells per milliliter. Mice were
inoculated subcutaneously in the right sub-scapular region with 5 x 10^6 EBC-I cells. Tumors were
monitored until they reached a mean volume of 300 mm^3.

Mice implanted with tumor cells were randomized into four groups often mice each treatment
was initiated (summarized in Table 6). Mice in Group 1 (control group) were treated with 100 µL
vehicle control, methylcellulose tween (MCT), every day (QD) via oral gavage (PO) and were
switched to drinking water containing 5% sucrose. Mice in Group 2 (c-met knockdown group) were
switched with 100 µL MCT, QD, PO, but were switched to drinking water containing 0.5 mg/mL of
doxycycline (Dox) in 5% sucrose. Mice in Group 3 (erlotinib treated group) were treated with 100
mg/kg of erlotinib in a volume of 100 µL formulated in MCT, QD, PO and were switched to drinking
water containing 5% sucrose. Mice in Group 4 (c-met knockdown plus erlotinib treated group) were
treated with 100 mg/kg of erlotinib in a volume of 100 µL formulated in MCT, QD, PO and were
switched to drinking water containing 1 mg/mL of doxycycline (Dox) in 5% sucrose. Dox and
sucrose water was changed every 2-3 days. Erlotinib and MCT were dosed for 14 days, stopped for 6
days and then resumed for the remainder of the study (20 days). Animals were taken off study if
tumors reached greater than 1000 mm^3 or tumors showed signs of necrotic lesions. If more than 3
animals had to be taken off study from any given group, treatment in that group was halted and all
animals were taken off study. All studies and handling of mice complied with the Institutional
Animal Care and Use Committee (IACUC) guidelines.

*in US patent application No. 61/034,446, Dox dosage was incorrectly stated to be 1 mg/ml. The correct dose is 0.5 mg/ml, as indicated above.

Tumor and Body Weight Measurement. Tumor volumes were measured in two dimensions (length and width) using UltraCal-IV calipers (Model 54-10-111, Fred V. Fowler Company, Inc.; Newton, MA). The following formula was used with Excel v1.2 (Microsoft Corporation; Redmond, WA).
WA) to calculate tumor volume:

\[
\text{Tumor Volume (mm}^3) = (\text{length} \cdot \text{width}^2) \cdot 0.5
\]

**Efficacy Data Analysis.** Tumor inhibition was plotted using KaleidaGraph 3.6 (Synergy Software; Reading, PA). Percent growth inhibition (%Ihn) at Day 17 was calculated as follows:

\[
\%\text{Ihn} = 100 \times \frac{\text{Tumor Size (Vehicle)} - \{\text{Tumor Size (MetMAb)/Tumor Size (Vehicle)}\}}{\text{Tumor Size (Vehicle)}}
\]

Tumor incidence (TI) was determined by the number of measurable tumors in each group at Day 17. Partial regression (PR) is defined as tumor regression of > 50% but < 100% of starting tumor volume at any day during the study. Complete regression (CR) is defined as tumor regression of 100% from initial starting tumor volume at any day during the study.

Mean tumor volume and standard error of the mean (SEM) were calculated using JMP software, version 5.1.2 (SAS Institute; Cary, NC). Data analysis and generation of p-values using either Student's t-test or the Dunnett's t-test was also done using JMP software, version 5.1.2.

**Results**

The combination of c-met knockdown and erlotinib treatment significantly inhibited tumor growth in a xenograft model.

To investigate the role of c-met in driving tumor growth in the EBC-I model, stable EBC-I clones that could be induced to express shRNAs to knockdown c-met expression were generated using retroviruses carrying a tetracycline-inducible short-hairpin RNA (shRNA) targeting c-met. The EBC-I non-small cell lung cancer (NSCLC) cell line is highly amplified for c-met and expresses high amounts of the c-met receptor which acts in a ligand-independent manner to drive cell and tumor growth. The EGFR gene is wildtype in the EBC-I cell line.

Following induction of shRNA expression with the tetracycline analog doxycycline, clone EBC-I shMet-3.15 showed efficient, largely complete knock-down of c-met expression. Induction of shRNA also blocked proliferation of these cells, as analyzed in Cell Titer Glo or Alamar Blue cell viability assays. Growth arrest followed by apoptosis was observed in EBC-I shMet3.15 cells 24-72 hours after shRNA induction. The same cell line clone was implanted into an animal model essentially as described above (except that animals were not treated with erlotinib) and permitted to form tumors. Induction of shRNA expression after tumor formation in these animals resulted in tumor regression in vivo. These results demonstrated that c-met expression is essential for the growth and survival of EBC-I cells in vitro and in vivo.

The EBC-I shMet-4.5 clone displayed partial knocked-down of c-met expression following induction of shRNA expression with Dox. Reduction in c-met expression also resulted in effects upon cell growth and survival in this clone: induction of shRNA expression decreased cell number when assayed in in vitro cell viability assays, and induction of shRNA expression after tumor formation in a xenograft model inhibited tumor growth but did not cause tumor regression.

Clone shMet-4.5 was selected for use in experiments evaluating the effect of combining knock-down of c-met expression with erlotinib treatment, as described below.
The EBC-I shMet-4.5 NSCLC cell line was inoculated into nude mice and then animals were monitored for tumor growth until the engrafted cells had formed tumors of about 300 mm$^3$. Mice were then grouped into four treatment arms; Group 1: Vehicles, Group 2: Doxycycline (Dox), Group 3: erlotinib (100 mg/kg), and Group 4: erlotinib + Dox (See Table 6).

Treatment of mice with erlotinib had no effect upon tumor growth (-6% tumor inhibition; Figure 4), whereas treatment with Dox (inhibiting met expression) resulted in 38% reduction in tumor growth compared to the vehicle control at day 19 (Figure 4: Student's t-test, $p = 0.084$), falling just shy of statistical significance. However, the reduction of tumor growth was statistically significant when compared with the erlotinib only group (Student's t-test, $p = 0.004$; Figure 4). Combination of erlotinib and Dox resulted in a dramatic improvement in efficacy, resulting in a 68% reduction in tumor growth compared to vehicle control at day 19 (Student's t-test, $p = 0.001$; Figure 4). Treatment with the combination of erlotinib and Dox also resulted in statistically significant reduction in tumor growth when compared with treatment with Dox alone (Student's t-test, $p = 0.03$) or treatment with erlotinib alone (Student's t-test, $p < 0.0001$).

Treatment with Dox and erlotinib resulted in a higher number of partial responses (PR; defined as tumor regression of > 50% but < 100% of starting tumor volume at any day during the study) and complete responses (CR; defined as tumor regression of 100% of initial starting tumor volume at any day during the study). Specifically, combination of erlotinib plus Dox resulted in 1 PR and 3 CRs, whereas treatment with erlotinib resulted in no PRs or CRs and treatment with Dox (c-Met knockdown) resulted in 2 PRs and 1 CR. These data demonstrate that the combination of met inhibition (Dox treatment) and EGFR inhibition (erlotinib treatment) is more likely to induce complete tumor regressions than inhibition of c-met or EGFR alone, even though analysis of the individual animal tumor data revealed that not all tumors responded strongly to the combination of c-met inhibition and erlotinib.

These results show that inhibition of c-met and EGFR in the EBC-I shMet-4.5 xenograft model resulted in a significant reduction in tumor growth. Thus, tumors in which c-met expression and activity are partially inhibited utilize the EGFR pathway to ensure tumor growth and survival. This indicates that EGFR plays a role in tumor survival and growth in tumors in which c-met is inhibited.

Example 4: Treatment with an anti-c-met antibody and the EGFR inhibitor erlotinib showed a dramatic improvement in efficacy verses treatment with anti-c-met antibody or erlotinib alone.

**Materials and methods**

**Test Material.** Anti-c-met monovalent monoclonal antibody MetMAb (rhuOA5D5v2) was provided by the Antibody Engineering Department at Genentech, Inc., in a clear liquid form at 10.6 mg/ml. The vehicle was 10 mM histidine succinate, 4% trehalose dihydrate, 0.02% polysorbate 20, pH 5.7. Erlotinib (TARCEVA™) was provided by OSI Pharmaceuticals to the Pharmaceutics Department at Genentech and was weighed out along with a sufficient amount of vehicle

88
(methylcellulose tween (MCT)). All material was shipped from Genentech, Inc. to the Van Andel Research Institute (VARI; Grand Rapids, MI) and was formulated prior to animal treatments.

Materials were stored in a refrigerator set to maintain a temperature range of 4°C to 8°C. The NCI-H596 cell line was obtained from American Type Culture collection (Manassas, VA). The Trasfectant/Vector system (methylcellulose tween (MCT)). All material was shipped from Genentech, Inc. to the Van Andel Research Institute (VARI; Grand Rapids, MI) and was formulated prior to animal treatments. Materials were stored in a refrigerator set to maintain a temperature range of 4°C to 8°C. The NCI-H596 cell line was obtained from American Type Culture collection (Manassas, VA).

Species. Forty human HGF transgenic C3H-SCID mice (hu-HGF-Tg-C3H-SCID) were obtained from the in-house colony at the Van Andel Research Institute (VARI; Grand Rapids, MI). Five C3H-SCID mice were obtained from Jackson Laboratories. Animals were 4-6 weeks old and weighed 21-22 grams each. Mice were acclimated to study conditions for at least three days prior to tumor cell inoculations. Mice were housed in a shower-in barrier facility. Animals were housed in ventilated caging systems in rooms with filters supplying High-Efficiency Particulate Air (HEPA).

Only animals that appeared to be healthy and were free of obvious abnormalities were used for the study.

Study design. As most HGF responsive tumors are driven in a paracrine fashion, a xenograft model that models paracrine driven growth was selected. Mouse HGF is a poor ligand for human c-met leading to a low biological response of human c-met expressing cells lines to mouse HGF (Bhargava, M., et al., 1992; Rong, S., et al., 1992). Therefore, to model paracrine HGF-driven human tumors, transgenic mice (hu-HGF-Tg-SCID) that express human HGF in a ubiquitous fashion from the metallothionein promoter were generated (Zhang, Y., et al., 2005). Serum HGF levels in the hu-HGF-Tg-SCID mice are ~5-10-fold higher than physiological levels (1-5 ng/mL vs. 0.2-0.5 ng/mL) and cells lines that respond to HGF by proliferating in vitro show a potent enhancement of tumor growth when grown as xenograft tumors in hu-HGF-Tg-SCID mice.

The NCI-H596 non-small cell lung cancer (NSCLC) cell line was selected as for in vivo efficacy studies in hu-HGF-Tg-SCID mice because the cell line is highly HGF responsive and an anti-c-met antibody, MetMab, blocks HGF-driven proliferation of this cell line in vitro (Kong-Beltran, M., et al., 2006). The NCI-H596 cell line bears a mutated form of the c-met gene lacking exon 14 that encodes a binding site for the E3 ubiquitin ligase Cbl (Kong-Beltran, M., 2006). The Cbl-binding site is phosphorylated at tyrosine 1003 (Y1 003) following HGF binding, allowing for Cbl to bind and ubiquitinate c-met, thus targeting it for proteosomal degradation (Peschard, P., et al., 2001). The responsiveness of NCI-H596 can also be seen in vivo, as the cell line readily form tumors in HGF-Tg-SCID mice (expressing human HGF, as noted above), but will not form tumors in immunocompromised mice lacking human HGF (nu/nu nude mice or SCID mice). NCI-H596 cells are considered to form c-met-driven tumors. NCI-H596 cells possess a wild-type EGFR gene and are sensitive to EGFR inhibitor erlotinib (TARCEVA™) when grown in the presence of TGFα as demonstrated by reduced cell viability when grown in the presence of erlotinib and TGFα.

NCI-H596 cells were cultured in growth media that consisted of RPMI 1640 media (Invitrogen), 2 mM L-glutamine, and 10% fetal bovine serum. To prepare cells for inoculation into mice, cells were trypsinized, washed with ten milliliters of sterile IX phosphate buffered saline (PBS).
A subset of cells was counted by trypan blue exclusion and the remainder of the cells was resuspended in 100 µl of sterile IX PBS to a concentration of 5 x 10^6 cells per milliliter.

Mice were prepared for inoculation by shaving the dorsal area with clippers. The following day each mouse was inoculated subcutaneously in the right sub-scapular region with 5 x 10^5 NCI-H596 cells. Tumors were monitored until they reached a mean volume of 100 mm^3.

HGF-Tg-C3H-SCID mice were randomized into two groups of eleven mice each and given an intraperitoneal injection of test material twice weekly for four weeks. Animals in Group 1 were given 100 µl of vehicle and animals in Group 2 were given 30 mg/kg of the anti-c-met monovalent monoclonal antibody MetMAb. The study design is presented in Table 7. Tumors were measured three times per week for five weeks, starting on the day of treatment. Mice were euthanized after five weeks, although some animals were euthanized earlier due to large tumor volumes (> 1500 mm3). Control C3H-SCID mice were also inoculated to serve as a negative control for tumor growth and were monitored for tumor growth for five weeks.

All studies and handling of mice complied with the Institutional Animal Care and Use Committee (IACUC) guidelines.

Tumor and Body Weight Measurement. Tumor volumes were measured in two dimensions (length and width) using UltraCal-IV calipers (Model 54-10-1 11, Fred V. Fowler Company, Inc.;
Newton, MA). The following formula was used with Excel v1.1.2 (Microsoft Corporation; Redmond, WA) to calculate tumor volume:

\[
\text{Tumor Volume (mm}^3\text{) = (length } \times \text{ width}^2\text{)} \times 0.5
\]

**Efficacy Data Analysis.** Tumor inhibition was plotted using KaleidaGraph 3.6 (Synergy Software; Reading, PA). Percent growth inhibition (%Inh) at Day 17 was calculated as follows:

\[
\%\text{Inh} = 100 \times \frac{\text{Tumor Size (Vehicle)} - \{ \text{Tumor Size (MetMAb)} / \text{Tumor Size (Vehicle)} \}}{\text{Tumor Size (Vehicle)}}
\]

Tumor incidence (TI) was determined by the number of measurable tumors in each group at Day 17. Partial regression (PR) is defined as tumor regression of > 50% but < 100% of starting tumor volume at any day during the study. Complete regression (CR) is defined as tumor regression of 100% from initial starting tumor volume at any day during the study.

Mean tumor volume and standard error of the mean (SEM) were calculated using JMP software, version 5.1.2 (SAS Institute; Cary, NC). Data analysis and generation of p-values using either Student's t-test or the Dunnett's t-test were performed using JMP software, version 5.1.2.

Kaplan-Meier survival curve estimates were drawn for time to tumor doubling for each group. Pairwise comparisons between groups were made. Statistical comparisons were made with the log-rank test. Data analysis was performed using JMP software.

**Results**

The NCI-H596 NSCLC cell line was inoculated into hu-HGF-Tg-C3H-SCID animals and animals were monitored for tumor growth until the engrafted cells had formed tumors of about 100 mm\(^3\). Mice were then grouped into four treatment arms: group 1: Vehicle, group 2: Erlotinib, group 3: MetMAb, and group 4: Erlotinib + MetMAb (See Table 7). Groups treated with MetMAb were dosed only once whereas groups treated with erlotinib were dosed every day for two weeks and then treatment was stopped and tumor growth was monitored two to three times per week. C3H-SCID control mice were also inoculated and monitored for growth of NCI-H596 tumors not exposed to human HGF.

Growth of NCI-H596 tumors was vastly improved in the context of the hu-HGF-Tg-C3H-SCID mice compared to the C3H-SCID control mice (Figure 5; compare vehicle control group to C3H-SCID). Treatment of mice with anti-c-met monovalent monoclonal antibody MetMAb resulted in a 67% reduction in tumor growth compared to the vehicle control at day 20 (Figure 5; Student's t-test, \( p = 0.0044 \)), consistent with previous studies of MetMAb in the NCI-H596 models. Treatment of NCI-H596 tumor-bearing mice with erlotinib resulted in a statistically insignificant reduction in tumor growth compared to the vehicle control at day 20 (Figure 5; Student's t-test, \( p = 0.165 \)). Treatment with the combination of MetMAb and erlotinib showed a dramatic improvement in efficacy, resulting in an 89% reduction in tumor growth compared to vehicle control at day 20 (Figure 5; Student's t-test, \( p = 0.0035 \)).

Treatment of mice with MetMAb resulted in a 67% reduction in tumor growth compared to the vehicle control at day 20 (Figure 5; Student's t-test, \( p = 0.0044 \)), consistent with previous studies.
of MetMAb in the NCI-H596 models. Treatment of NCI-H596 tumor-bearing mice with erlotinib resulted in a statistically insignificant reduction in tumor growth compared to the vehicle control at day 20 (Figure 5; Student's t-test, $t = 0.165$). Treatment with the combination of MetMAb and erlotinib showed a dramatic improvement in efficacy over either agent alone, resulting in an 89% reduction in tumor growth compared to vehicle control at day 20 (Figure 5; Student's t-tests; MetMAb + erlotinib vs. vehicle, day 20 - $p = 0.0035$; MetMAb + erlotinib vs. erlotinib alone, day 26 - $p = 0.0009$; MetMAb + erlotinib vs. MetMAb alone, day 45 $p = 0.0149$).

Tumor volume data were collected for nine weeks after the dosing ended to address whether the combination of MetMAb plus erlotinib resulted in improvements in time to tumor progression. To address this issue, time to tumor doubling (TTD) measurements, defined as the time it took for tumors to double in size, were calculated for each group and used to generate Kaplan-Meier survival curves. The combination of MetMAb plus erlotinib showed a dramatic improvement in time to tumor progression with a mean TTD of 49.5 (± 2.6) days versus 17.8 (± 2.2) days for the MetMAb-treated group, 9.5 (± 1.2) days for the erlotinib-treated group, and 9.5 (± 1.2) days for vehicle control group (Figure 6). These data show that the combination of MetMAb plus erlotinib significantly improves the time to tumor progression versus either single agent alone (Log-rank test; vehicle vs. MetMAb - $p < 0.0001$; vehicle vs. MetMAb + erlotinib - $p < 0.0001$; erlotinib vs. MetMAb + erlotinib $p < 0.0001$ and MetMAb vs. MetMAb + erlotinib - $p = 0.0009$).

These data demonstrate that treatment with the combination of MetMAb and erlotinib results in highly significant improvements in tumor growth inhibition and tumor progression relative to treatment with MetMAb or erlotinib alone.

Example 5: C-met signaling regulates EGFR signaling

**Materials and methods**

**Microarray analyses:** Three microarray experiments were performed using Affymetrix HGU133 Plus 2.0 arrays. In each case, preparation of complementary RNA, array hybridizations, and subsequent data analysis were carried out using manufacturer protocols, essentially as described in Hoffman EP et al., Nat Rev Genet 5:229-37 (2004). Raw expression data, in the form of Affymetrix CEL files, were normalized as a group to remove non-biological sources of variation between data for individual samples using the RMA method of normalization (Irizarry, Biostatistics, 2003, PubMed ID 12925520) as implemented in the Partek GS 6.3b software package (Partek, Saint Louis, MO). The resulting normalized, log2 scale expression values were analyzed as follows and were transformed to the linear scale for plotting purposes.

In the first experiment, ligand-responsive NSCLC HOP92 and H596 cells were untreated or stimulated with 50 ng/ml HGF for 6 hrs before mRNA expression profiling. Briefly, cells were plated in 6-well plates at approximately 5x10^5 cells/well. After a day, cells were washed, then transferred to RPMI media + 0.1% BSA. On day 3, cells were stimulated for 6h with HGF at 50 ng/ml in RPMI medium + 0.1% BSA. Cells were washed once with cold PBS, lysed with RNAeasy lysis buffer, and
RNA prepared according to the manufacturer's protocol. HOP92 and H596 samples were analyzed separately using a t-test to measure the significance (P-value) of the difference in expression levels for each gene in the + HGF and - HGF conditions. These P-values were converted to Q-values by correcting for multiple testing using the Benjamini and Hochberg method (Benjamini and Hochberg, 1995). Genes were then ranked on statistical significance (Q-value) of the expression level difference in each cell line.

In the second experiment, mRNA expression levels of clones EBCshMet3-15 and EBCshMet4-12 were assayed after 24 and 48 hrs of incubation with or without 50 ng/ml doxycycline. The expression pattern of each Affymetrix probe set (gene) was analyzed using a linear statistical model (ANOVA) that estimated the effect of the clone (3-15 or 4-12), treatment (control or doxycycline), and time-point (24 or 48 hours) as well as the interaction of time-point and treatment effects. The ANOVA procedure produced measures of significance (P-values) for each of these four effects. These P-values were converted to Q-values by correcting for multiple testing using the Benjamini and Hochberg method. Genes were then ranked on statistical significance (Q-value) of the expression level difference between doxycycline and control samples.

In the third experiment, EBCMet shRNA 4-12 cell or control EBCGFp shRNA cells were incubated in media alone or media with 50 ng/ml doxycycline for 24h. After further treatment (+/- HGF 100 ng/ml for 2 hours), mRNA expression was assayed by microarray. The expression pattern of each Affymetrix probe set (gene) was analyzed using a linear statistical model (ANOVA) that estimated the effect of the shRNA target (Met or GFP), shRNA induction (doxycycline or control), and HGF treatment as well as the interaction of these three variables. These P-values were then converted to Q-values of the expression level difference between plus-HGF and minus-HGF conditions in doxycycline-treated EBCMetshRNA4-12 samples. Using cutoff of a Q-value of 0.05 (5% False Discovery Rate) and a two-fold expression change for the comparison of the +/- HGF groups, 188 probesets were selected.

TGFαELISA: EBC-1-shMet xenograft tumors were generated and Dox was dosed essentially as described in Example 3, except that Dox was used at 1 mg/ml in 5% sucrose and tumors were allowed to grow to 300-400 mm3 prior to initiation of treatment. Animals were dosed for 3 days, then sacrificed. Flash frozen EBC-1 -shMet-4. 12 xenograft tumor samples were placed into 2mls of cold lysis buffer (PBS + 1%TritionX-100 + Phosphatase Cocktail 2 (Sigma cat# P5726)) and Complete Mini EDTA-Free protease inhibitor (Roche #11836 170 001)(1 tablet per 10mls of solution). Tumors were homogenized with a hand held homogenizer and lysates were incubated on ice for 1hr with occasional swirling. Lysates were spun down at 10000xG for 10 minutes at 4°C, transferred to a new tube and Her 3 protein was quantified using a BCA assay (Pierce cat# 23225).

Anti-TGF-alpha polyclonal antibody (R&D Systems, Minneapolis, MN) was diluted to 1 µg/ml in phosphate buffered saline (PBS) and coated onto ELISA plates (25 µL/well, 384 well plates with MaxiSorp surface, Nunc, Neptune, NJ) during an overnight incubation at 4°C. After washing 6
times with wash buffer (PBS / 0.05% Tween-20), the plates were blocked with PBS / 0.5% bovine serum albumin (BSA) for 1 to 2 hr. This and all subsequent incubations were performed at room temperature on an orbital shaker. Samples were diluted using sample buffer (PBS / 0.5% BSA / 0.5% Tween-20 / 0.2% bovine gamma globulin / 0.25% CHAPS / 5 mM EDTA / 10 ppm Proclin). Using the same buffer, serial dilutions were prepared of recombinant human TGF-alpha (R&D Systems), with a standard curve range of 400 - 12.5 pg/ml. Frozen control samples pre-diluted to quantitate at the high, mid, and low regions of the standard curve were thawed. Plates were washed six times, and the samples, standards, and controls were added (25 µL/well) and incubated for 2 hr. After washing the plates twelve times, biotinylated goat anti-TGFalpha polyclonal antibody (R&D Systems) diluted to 1 µg/ml in sample buffer was added (25 µL/well). Following a one hour incubation, the plates were washed twelve times. Streptavidin-horse radish peroxidase (GE Healthcare, Piscataway, NJ) diluted 1/4,000 in sample buffer was then added (25 µL/well). After a final 30 min incubation, the plates were washed twelve times, and tetramethyl benzidine (TMB, Kirkegaard & Perry Laboratories, Gaithersburg, MD) was added. Color was allowed to develop for 6 to 8 minutes at room temperature, and the reaction was stopped by the addition of 1 M phosphoric acid. Absorbance values were obtained using a microplate reader (450 nm, 620 reference), and the sample concentrations were calculated from 4-parameter fits of the standard curves.

**Results**

Activation of c-met by HGF treatment increased mRNA expression of EGFR ligands (HB-EGF, Epiregulin, Amphiregulin, TGFα) in ligand-responsive NSCLC cell lines Hop-92 and NCI-H596 (Figure 9A). Conversely, inhibition of c-met expression using shRNA in ligand-independent NSCLC cell line EBC1 cells reduced mRNA expression of those EGFR ligands (Figure 9B). HGF treatment of dox-treated EBC1-shMet cell line 4-12 restored expression of EGFR ligands (Figure 9C). Reduction of EGFR ligands did not occur in control EBC-I cells that expressed a siRNA directed against GFP (Figure 9D). Reduction of c-met expression in EBC-1-shMet xenograft tumors resulted in a decrease in tumor TGFα protein levels at day 3 post-treatment (Figure 9E).

These data demonstrate that c-met activity can regulate EGFR signaling in c-met amplified HGF-independent cells (EBC1) as well as HGF-dependent cell lines (Hop92 and NCI-H596). More specifically, c-met signaling increased and maintained expression of EGFR family of ligands, which could then stimulate their own EGFR family of receptors in an autocrine manner. Conversely, inhibition of c-met signaling resulted in decreased expression of EGFR ligands. Interference with this autocrine loop is a likely cause of the decreased pEGFR observed in EBC1 cells following c-met knockdown (Figure 10) and the increased sensitivity to ligand-induced activation of EGFR following c-met knockdown described in Example 2. These results suggest that EGFR activity can compensate for loss of c-met signaling activity in HGF-dependent and HGF-independent tumors, and are consistent with the dramatically increased xenograft tumor efficacy observed when tumors were treated with the combination of EGFR and c-met inhibitors (Example 4).
Example 6: C-met activity regulates HER3 expression.

Materials and methods

Western blot analysis of pEGFR and Her3 protein: Cells were plated at a density of 1x10^6 and incubated 18 hours at 37°C in 10% Tet-approved FBS in RPMI 1640. The next day, media was removed and replaced with fresh normal media, with or without 0.1 ug/ml Dox. 24, 48 and 72 hours after changing media, proteins were extracted with 1% NP-40/TBS/Roche's Complete protease inhibitor cocktail/Sigma’s phosphatase inhibitor cocktails 1 and 2 after a cold TBS rinse. 15 ug of total protein was loaded on Invitrogen's 4-12% Bis-Tris NUPAGE gel with MOPS buffer and transferred to PVDF by Invitrogen's iBlot. Membranes were immunoblotted for phosphorylated proteins (pEGFR (Y1 173) Upstate 04-341 at a dilution of 1:1000 in 5% BSA/TBST), stripped with Pierce's Restore stripping buffer, then reprobed for total proteins (c-met: SCBT sc-10 at 1:10,000 dilution; Her3: SCBT sc-285 at 1:2000 dilution in 5% nonfat dry milk and TBST). Proteins were detected with Amersham's HRP-conjugated secondary antibodies (Amersham anti-rabbit-HRP, #NA934V; Amershams anti-mouse-HRP) using Amersham's ECL Plus chemiluminescent kit according to the manufacturer's instructions.

Her3 FACS: EBC-I shMet 4-12 cells were seeded at 1x10^6 cells per 10 cm plate in RPMI 1640 (as above) and plates were incubated overnight. Dox was added to plates to a final concentration of 100ng/ml. Plates were incubated for 48 hours. Following incubation, cells were trypsinized, centrifuged, then resuspended in cold 200 μL PBS + 2%FBS (FACS Buffer) and transferred to 96 well plates. Cells were spun down and resuspended in FACS buffer plus 10 μg/ml of Her3:1638 (3E9.2G6) antibody from Genentech. Cells were incubated for 1 hour on ice, then washed with cold FACS Buffer and resuspended in FACS buffer + 1:200 RPE conjugated F(ab')2 Goat anti-mouse IgG + IgM (H+L) (Jackson Immuno cat# 115-1 16-068). Cells were incubated on ice for 30 minutes, then washed once with cold FACS buffer and resuspended in FACS buffer plus 7AAD (BD Pharmingen cat#559925). FACS analysis was performed according to the manufacturer's instructions.

Tumor Lysates: EBC-I shMet xenograft tumors were generated and Dox was dosed essentially as described in Example 3, except that Dox was used at 1 mg/ml in 5% sucrose and tumors were allowed to grow to 300-400 mm³ prior to initiation of treatment. Animals were dosed for three days, then sacrificed. Flash frozen EBC-I shMet-4.12 xenograft tumor samples were placed into 2 mls of cold lysis buffer (PBS + 1%TritonX-100 + (3X) Phosphatase Cocktail 2 (Sigma cat# P5726)) and Complete Mini EDTA-Free protease inhibitor (Roche #11 836 170 001). Tumors were homogenized with a hand held homogenizer and lysates were incubated on ice for 1hr with occasional swirling. Lysates were spun down at 10000xG for 10 minutes at 4°C, transferred to a new tube and Her 3 protein was quantified using a BCA assay (Pierce cat# 23225).

Results

shRNA-mediated knock-down of c-met expression reduced pEGFR levels and significantly increased HER3 protein levels (Figure 10A). FACS analysis revealed increased surface HER3 levels
after c-met knockdown (Figure 1OB). C-met knockdown in EBC-IshMet-4.12 xenograft tumors resulted in an increase in HER3 protein levels (Figure 1OC).

These data demonstrate that c-met activity can regulate HER3 expression level. Specifically, c-met inhibition resulted in increased HER3 protein levels and decreased pEGFR levels. The decrease in pEGFR after c-met inhibition is likely due to decreased autocrine signaling by EGFR ligands (see Figure 9) and increased HER3 levels might increase erlotinib sensitivity, as has been demonstrated by others (e.g., Yauch et al. Clin Cancer Res (2005) 11:8686-98). These results suggest that HER3 activity (e.g. signaling through HER2) may increase following inhibition of c-met signaling, and further support the use of combination therapy with c-met and HER3 inhibitors for the treatment of cancer.

Example 7: EGFR pathway activation can restore cell proliferation and viability of cell in which c-met activity is inhibited.

Materials and methods

EBC-I shMet cells were seeded at 5000/well in RPMI 1640 medium (containing 10% Tet-Free FBS from Clontech cat# 631107) in a black-walled 96 well plate, and plates were incubated overnight. Media was replaced with fresh media +/- 100ng/ml dox, and plates were incubated for 48 hours. EGFR ligands were then added to final concentrations described below, and plates were incubated for an additional 48 hours then cell number was determined using Cell TiterGlo (Promega #G7570) as described herein: Dox + 100ng/ml HGF; Dox + 50nM TGFα; Dox + 5ng/ml HGF; and Dox + InM TGFα.

Results

Knockdown of c-met expression by shRNA resulted in a significant decrease in cell number, implying a decrease in cell viability and proliferation. EGFR ligands HGF and TGFα were capable of rescuing cell number in a dose-dependent manner, although HGF appeared to rescue cell number somewhat better than TGFα. These results demonstrated that EGFR pathway activation can restore cell proliferation and cell viability in cells in which c-met signaling activity is inhibited. Thus, EGFR (and/or other HER family members) signaling compensated for loss of c-met signaling activity. These results support the use of combination therapy with c-met and EGFR inhibitors, and are consistent with the dramatically increased xenograft tumor efficacy observed when tumors were treated with the combination of EGFR and c-met inhibitors (Example 4).

Example 8: Activation of c-met results in activation of EGFR. c-met interacts with EGFR independently of c-met or EGFR pathway activation, and activation of c-met attenuated response to EGFR inhibitor.

Materials and methods

Cells: NCI-H596 cells were obtained from the American Type Culture Collection (ATCC) and were maintained in RPMI 1640 supplemented with 10% fetal bovine serum (FBS; Sigma, St. Louis, MO), and 2 mM L-glutamine. Cell assay media was changed as described below depending
upon the experiment.

Therapeutics and Growth factors: Erlotinib and MetMAb were from Genentech, Inc., as described above. HGF and TGF-α were generated at Genentech.

Immunoprecipitations and Immunoblotting: Cells were starved overnight in 0.1% BSA/RPMI prior to stimulation with ligand and/or dosing with compound, as described in the text. HGF and TGF-α ligands were generated in-house. At the time of harvesting, cells were immediately washed once in ice cold PBS followed by lysing in lysis buffer (CST #9803) supplemented with 1 mM of each of the following: Protease Inhibitors (Sigma Cat #P3840), Phosphatase Inhibitors (Sigma Cat # P2850 and P3726), NaF, Na3VO4 and PMSF. Samples were placed on a 180° rotator at 4°C, followed by clearing at 14,000 rpm, 20 min 4°C. Protein concentration was estimated using the Bradford Assay.

Cell lysates were either directly loaded onto gels (Figure 12, equivalent lysate concentration of 40 μg/lane) or immunoprecipitated (Figure 13, equivalent lysate concentration of 1.6 mg/sample). Immunoprecipitation was performed with each of the following antibodies; agarose conjugated cMET:(Santa Cruz Biotechnology Cat #SC-161AC), EGFR (Neomarkers MS-609-P) + Protein A Sepharose Fast Flow Beads. Samples were placed on a 180° rotator, 4°C overnight, followed by three washes with lysis buffer and subsequently denatured in SDS sample buffer containing beta-mercaptoethanol. Samples were heated for 5 min at 95°C followed by loading on 4-12% gradient gels and transferring onto nitrocellulose membranes using standard western blotting procedures.

Membranes were blocked in 5% milk/TBST for 1 hr, RT and then probed with the following phospho-antibodies overnight at 4°C, as indicated in the text: p-c-met: pTyr 4G10 (Upstate Cat# 05-777); pEGFR (Cell Signaling Technologies Cat # 2264). Membranes were stripped with Restore Stripping Buffer (Pierce Cat # 21059) and re-probed with antibodies to total protein: cMET DL-21 (Upstate Biotech Cat #05-238); EGFR (MBL Cat # MI-12-1); beta actin (Santa Cruz Biotechnologies Cat #SC-1616). Secondary antibodies were obtained from Jackson Laboratories. Immunoblots were detected using the ECL Method, as per manufacturer recommendations.

Cell Viability Assays: For cell viability assays, cells were plated in quadruplicate at 1x10^3 cells per well in 384-well plates in RPMI containing 0.5% FBS (assay medium) overnight, prior to stimulation with assay medium containing 3 nM TGF-α +/- HGF. Erlotinib was added at multiple concentrations and 72 hours later, cell viability was measured using the Celltiter-Glo Luminescent Cell Viability Assay (Promega, Madison, WI).

Results

Activation of c-met with HGF results in activation of EGFR.

Since activation of c-met resulted in the upregulation of numerous EGFR ligands in NCI-H596 cells, we hypothesized that c-met activation results in transactivation of the EGFR pathway. To test this hypothesis, NCI-H596 NSCLC cells were treated with or without HGF in vitro, and cell lysates were analyzed at ten minutes, 24, 48 and 72 hours to examine EGFR pathway activation.
Activation of c-met signaling resulted in activation of EGFR signaling (Figure 12). Induction of pEGFR level was observed as early as ten minutes following HGF stimulation, suggesting that c-met activation directly transactivates EGFR signaling (Figure 12). Increased levels of pEGFR were observed at the later time points (24, 48, and 72 hours following HGF stimulation) (Figure 12). The delayed pEGFR activation kinetics are consistent with data showing that c-met activity results in increased expression of EGFR ligands, which could be responsible for delayed (>24 hour) EGFR pathway activation. In this model, activation of EGFR would be predicted to increase at later time points and remain relatively high, consistent with the data shown here.

**C-met interacts with EGFR independent of c-met or EGFR pathway activation status.**

Co-immunoprecipitation experiments (co-IPs) were performed to determine whether c-met and/or EGFR activity might result in physical association of c-met with EGFR. NCI-H596 cells were treated with no ligand, TGFα alone, HGF alone, or TGF-a plus HGF for 10 minutes or 24 hours. Following this treatment, c-met was immunoprecipitated followed by western blotting for either phospho-tyrosine (4G10), EGFR or c-met.

C-met immunoprecipitation pulled down EGFR in the absence of either ligand and at later time points when pc-met and pEGFR levels had dropped, indicating that c-met interacted with EGFR regardless of c-met or EGFR pathway activation status (Figure 13). The c-met IPs blotted for phospho-tyrosine revealed that EGFR and c-met activation was ligand-dependent and attenuated after 24 hours. Activation of c-met by HGF resulted in co-immunoprecipitation of pEGFR; however pEGFR levels were much lower than pEGFR levels observed when cells were stimulated with TGFα alone or in combination with HGF. Activation of c-met or EGFR by their respective ligands showed that each pathway could be activated independently of one another.

**Activation of c-met attenuated the response of NCI-H596 cells to EGFR inhibitor and treatment with anti-c-met antibody MetMAb rescued the response to EGFR inhibitor.**

NCI-H596 cells are sensitive to EGFR inhibitor erlotinib (TARCEVA™) when grown in the presence of TGFα, as demonstrated by reduced cell viability when grown in the presence of erlotinib and TGFα. To determine whether activation of the c-met pathway could change the response of NCI-N596 cells to erlotinib, cells were stimulated with TGFα, treated with erlotinib and/or HGF, then cell viability was assayed.

Low levels of HGF showed modest effects upon cell sensitivity to erlotinib; however sensitivity to erlotinib was dramatically reduced in a dose-dependent manner as HGF concentrations increased (Figure 14), as revealed by increased cell viability under these conditions. These data indicate that HGF activation of the Met pathway is sufficient to attenuate the response of NCI-H596 cells to erlotinib.

To determine whether the combination of c-met inhibitors and EGFR inhibitors reduced cell viability of cell lines that are co-activated by HGF and TGFα, NCI-H596 cell viability assays were performed in the presence of HGF, TGFα, and varying doses of erlotinib and/or c-met antagonist
antibody MetMAb (1 uM).

Presence of HGF attenuated response of NCI-H596 cells to erlotinib (Figure 15). Inhibition of the c-met pathway by MetMAb dramatically restored erlotinib sensitivity (Figure 15), thus suggesting that treatment with c-met and EGFR inhibitors can have combination effects impacting cell viability in the NCI-H596 cell line.

Taken together, these studies support the hypothesis that activation of the c-met pathway directly activated the EGFR pathway, both through induction of EGFR ligand expression as well as through direct interaction between c-met and EGFR. These results are consistent with dramatically increased xenograft tumor efficacy observed when tumors were treated with the combination of EGFR and c-met inhibitors (Example 4).

Example 9: Combination treatment with c-met antagonist and EGFR antagonist resulted in better inhibition of proliferation and survival signaling pathways in NCI-H596 xenograft tumors.

**Materials and methods**

**NCI-H596 hu-HGF-Tg-SCID xenograft tumors:** NCI-H596 xenografts were established in hu-HGF-Tg-SCID mice as described in Example 4. Tumors were allowed to grow to 200-300 mm³ prior to treatment. Dosing was performed as described in Table 8. Briefly, MetMAb (30 mg/kg) or MetMAb buffer was dosed at time zero hours (0 hr) and methylcellulose tween vehicle (MCT) or erlotinib (150 mg/kg) was dosed at time 18 hours (18 hr). Mice were euthanized and tumors and plasma collected at time 24 hours (24 hr). Tumors were snap frozen in liquid nitrogen and then kept at -70°C until they were processed for immunoprecipitation and immunoblotting.

Immunoprecipitations and Immunoblotting: To process tumors for protein analysis, tumors were first homogenized using a glass dounce with lysis buffer (Cell Signaling Technology, Inc., Danvers, MA), supplemented with 1 mM PMSF, additional protease inhibitor cocktail, and phosphatase inhibitor cocktail I and II (Sigma, Inc., St. Louis, MO). Lysates were incubated on ice for one hour and then centrifuged at 14,000 x g for five minutes and supernatants collected. Protein concentrations were determined using the BCA™ Protein Assay Kit (Pierce, Inc., Rockford, IL) and samples were immunoblotted. For immunoprecipitations, 1.5 mg of tumor lysates was used to pull down Met, using the C-28 anti-human c-Met polyclonal antibody (Santa Cruz Biotechnology, Inc., Santa Cruz, CA) conjugated agarose beads, or EGFR, using the MI-12-1 antibody (MBL, Inc., Woburn, MA) at 4°C overnight with rotation. The beads were washed three times with lysis buffer at 4°C followed by resuspension in IX Novex Tris-Glycine SDS Running Buffer (Invitrogen, Inc., Carlsbad, CA) containing 2.5% (w/v) beta-mercaptoethanol. For direct Western blots, 50 µg of tumor lysate was loaded per lane. Samples were then analyzed by SDS-PAGE and immunoblotting. Antibodies used include the mouse anti-human c-Met DL-21, mouse anti-phosphotyrosine mAb 4G10 (both from Upstate Biotechnology/Millepore, Inc., Charlottesville, VA), anti-Akt, anti-p44/42 MAP kinase (ERK-1/2), anti-phospho-Akt (Ser473), anti-phospho-p44/42 MAP kinase (ERK-1/2) (Thr202/Tyr204), all used according to manufacturer's recommendations (all from Cell Signaling...
Technology, Inc. (Danvers, MA)). Goat-anti-mouse-IRdye800 (Rockland Immunochemicals, Inc., Gilbertsville, PA) and goat-anti-rabbit-AlexaFluor680 (Molecular Probes, Inc., Eugene, OR) were used as secondary antibodies. Immunoblots were imaged and phospho-protein levels were quantified and normalized to total protein levels (e.g. pEGFR over total EGFR) using an Odyssey imager (LI-COR Biosciences, Lincoln, NE).

**Results**

C-met and EGFR pathway activation were examined in xenograft tumors generated in the NCI-H596 hu-HGF-Tg-SCID mouse xenograft model and treated with EGFR inhibitor, c-met inhibitor and the combination of EGFR and c-met inhibitors. Twenty hu-HGF-Tg-SCID mice were inoculated with NCI-H596 cells and tumors established, as previously described. Once tumors reached sizes between 200-300 mm³, mice were evenly grouped into four groups based upon tumor volume and dosing was begun (Table 8). MetMAb was dosed 24 hours prior to tumor harvest whereas erlotinib was dosed 6 hours prior to harvest. Dosing times were selected based on the relative half-life of each therapeutic agent. At 24 hours, mice were euthanized and tumors were collected and tumors were processed for immunoprecipitations (IPs) and/or immunoblots against phosphorylated and total Met, EGFR, Akt and ERK-1/2.

Treatment with MetMAb alone resulted in inhibition of c-met phosphorylation to 12% (+/- 3.6%) of vehicle control (Figure 16), and combined treatment with MetMAb and erlotinib resulted in inhibition of c-met phosphorylation to 6% (+/- 3.5%) of vehicle control (Figure 16) (p = 0.039). Treatment with erlotinib alone (Figure 16) did not reduce c-met phosphorylation. Treatment with erlotinib alone inhibited phosphorylation of EGFR to 16% (+/- 7.9%) of vehicle control and combined treatment with erlotinib and MetMAb inhibited phosphorylation of EGFR to 19% (+/- 15%) of vehicle control (Figure 16). Treatment with MetMAb alone also modestly inhibited pEGFR to 62% (+/- 21.6%) of vehicle control (p = 0.006).

These results demonstrated that MetMAb and erlotinib each effectively inhibit activation of their respective targets and that blockade of c-met can inhibit pEGFR response in the NCI-H596 hu-HGF-Tg-SCID model.

Combined treatment with MetMAb and erlotinib also resulted in more effective inhibition of PI-3K/Akt and the Ras-RAF-MEK-ERK1/2 pathways which are activated downstream of activated Met and EGFR, where the pathways act to activate tumor cell survival and proliferation, respectively, and help drive oncogenesis. Phospho-Akt and phospho-ERK-1/2 was examined in xenograft tumors from animals treated with MetMAb, erlotinib or MetMAb plus erlotinib.

Treatment with MetMAb alone resulted in inhibition of pAkt to 72% (+/- 27.9%) of vehicle control and inhibition of pERK-1/2 to 72% (+/- 40.3%) of vehicle control (Figure 15, Table 9). Erlotinib treatment resulted in a more robust inhibition of pAkt to 45% (+/- 25.7%) and ERK-1/2 by 39% (+/- 8.9%) of vehicle controls, respectively (Figure 16, Table 9). Treatment with the combination of MetMAb and erlotinib showed improved inhibition of pAkt and pERK-1/2 to 24%
(+/- 13.8%) of vehicle control and 29% (+/- 2.9%) of vehicle control, respectively (Figure 15, Table 9). These results demonstrated that combined treatment with MetMAb and erlotinib inhibited downstream signaling pathways more effectively than treatment with MetMAb or erlotinib alone.

Table 9. Summary of the quantified levels of phospho-proteins*, as percent of vehicle control, following treatment of NCI-H596 tumor bearing mice with MetMAb, erlotinib or the combination of MetMAb and erlotinib. Phospho-protein levels were determined by quantifying signal intensity of bands by Li-Cor then normalizing to total protein levels (minus background). Data are represented as a percent of the vehicle control (values represent an average of tumors from 5 treated different animals each as shown in Figure 16).

Figures 17A and 17B diagrammatically summarize some of the findings disclosed herein as follows:

1. c-met and EGFR were co-expressed in NSCLC cell lines and tumors;
2. c-met activity positively regulated expression of EGFR ligands and pEGFR;
3. c-met activity negatively controlled expression of HER3;
4. TGFα treatment rescued ligand-independent c-met activated cells from c-met inhibitor-mediated loss of viability; and
5. c-met activation reduced response to erlotinib in vitro and in vivo.

xenografts in a new strain of immunocompromised mice transgenic for human hepatocyte growth

Although the foregoing invention has been described in some detail by way of illustration and
example for purposes of clarity of understanding, the descriptions and examples should not be
construed as limiting the scope of the invention.
What is claimed is:

1. A method of treating cancer in a subject, comprising administering to the subject a therapeutically effective amount of a c-met antagonist and an EGFR antagonist.

2. The method of claim 1, wherein the EGFR antagonist has a general formula 1:

![Chemical Structure](image)

in accordance with US 5,757,498, incorporated herein by reference, wherein:

- m is 1, 2, or 3;
- each R\(^1\) is independently selected from the group consisting of hydrogen, halo, hydroxy, hydroxyamino, carboxy, nitro, guanidino, ureido, cyano, trifluoromethyl, and -(C\(_1\) - C\(_4\) alkylene)-W-(phenyl) wherein W is a single bond, O, S or NH;
- or each R\(^1\) is independently selected from R\(^9\) and C\(_1\) - C\(_4\) alkyl substituted by cyano, wherein R\(^9\) is selected from the group consisting of R\(^5\), -OR\(^6\), -NR\(^6\) R\(^6\), -C(O)R\(^7\), -NHOR\(^5\), -OC(O)R\(^6\), cyano, A and -YR\(^5\); R\(^5\) is C\(_1\) - C\(_4\) alkyl; R\(^6\) is independently hydrogen or R\(^5\); R\(^7\) is R\(^5\), -OR\(^6\) or -NR\(^6\) R\(^6\); A is selected from piperidino, morpholino, pyrrolidino, 4-R\(^6\)-piperazin-1-yl, imidazol-1-yl, 4-pyridon-1-yl, -(C\(_1\) - C\(_4\) alkylene)(CO2H), phenoxy, phenyl, phenylsulfanyl, C\(_2\) - C\(_4\) alkenyl, and -(C\(_1\) - C\(_4\) alkylene)C(O)NR\(^6\) R\(^6\); and Y is S, SO, or SO\(_2\);
- wherein the alkyl moieties in R\(^5\), -OR\(^6\) and -NR\(^6\) R\(^6\) are optionally substituted by one to three halo substituents and the alkyl moieties in R\(^5\), -OR\(^6\) and -NR\(^6\) R\(^6\) are optionally substituted by 1 or 2 R\(^9\) groups, and wherein the alkyl moieties of said optional substituents are optionally substituted by halo or R\(^9\), with the proviso that two heteroatoms are not attached to the same carbon atom;
- or each R\(^1\) is independently selected from -NHSO\(_2\) R\(^5\), phthalimido-(C\(_1\) - C\(_4\))-alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido, 2-oxopyrrolidin-1-yl, 2,5-dioxopyrrolidin-1-yl, and R\(^{10}\)-(C\(_2\) - C\(_4\))-alkanoylamino wherein R\(^{10}\) is selected from halo, -OR\(^6\), C\(_2\) - C\(_4\) alkanoyloxy, -C(O)R\(^7\), and -NR\(^6\) R\(^6\); and wherein said -NHSO\(_2\) R\(^5\), phthalimido-(C\(_1\) - C\(_4\))-alkylsulfonylamino, benzamido, benzenesulfonylamino, 3-phenylureido,
2-oxopyrrolidin-1-yl, 2,5-dioxopyrrolidin-1-yl, and R^1\text{0}\text{-(C}_2\text{-C}_4\text{)}-alkanoylamino R^1\groups are optionally substituted by 1 or 2 substituents independently selected from halo, C_1\text{-C}_4 alkyl, cyano, methanesulfonyl and C_1\text{-C}_4 alkoxy;

or two R^1\groups are taken together with the carbons to which they are attached to form a 5-8 membered ring that includes 1 or 2 heteroatoms selected from O, S and N;

R^2 is hydrogen or C_1\text{-C}_6 alkyl optionally substituted by 1 to 3 substituents independently selected from halo, C_1\text{-C}_4 alkoxy, -NR^6R^6, and -SO_2R^3;

n is 1 or 2 and each R^3 is independently selected from hydrogen, halo, hydroxy, C_1\text{-C}_4 alkyl, -NR^6R^6, and C_1\text{-C}_4 alkoxy, wherein the alkyl moieties of said R^3 groups are optionally substituted by 1 to 3 substituents independently selected from halo, C_1\text{-C}_4 alkoxy, -NR^6R^6, and -SO_2R; and

R^4 is azido or -(ethynyl)-R^\text{11} wherein R^\text{11} is hydrogen or C_1\text{-C}_6 alkyl optionally substituted by hydroxy, -OR^6, or -NR^6R^6.

3. The method of claim 2, wherein the EGFR antagonist is a compound according to formula I selected from the group consisting of:

(6,7-dimethoxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-[3-(3’-hydroxypropyn-l-yl)phenyl]-amine; [3-(2’-(aminomethyl)-ethynyl)phenyl]-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-nitroquinazolin-4-yl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(4-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethynyl-2-methylphenyl)-amine; (6-aminoquinazolin-4-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(6-methanesulfonylaminoquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6,7-methylenedioxyquinazolin-4-yl)-amine; (6,7-dimethoxyquinazolin-4-yl)-(3-ethynyl-6-methylphenyl)-amine; (3-ethynylphenyl)-(7-nitroquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-carbomethoxyquinazolin-4-yl)-(3-ethynyl-6-methylphenyl)-amine; (3-ethynylphenyl)-(7-nitroquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6,7-bis(2-toluensulfonylamino)quinazolin-4-yl)-amine; (3-ethynylphenyl)-[6-[2’-phthalimido-eth-1’-yl- sulfonylamino]quinazolin-4-yl]-amine; (3-ethynylphenyl)-(6-guanidinoquinazolin-4-yl)-amine; (7-aminoquinazolin-4-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(7methoxyquinazolin-4-yl)-amine; (6-carbomethoxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; (7-carbomethoxyquinazolin-4-yl)-(3-ethynylphenyl)-amine; [6,7-bis(2methoxyethoxy)quinazolin-4-yl]-(3-ethynylphenyl)-amine; (3-azidophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-azido-5-chlorophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (4-azidophenyl)-(6,7-dimethoxyquinazolin-4-yl)-amine; (3-ethynylphenyl)-(6-methansulfonyl-quinazolin-4-yl)-amine; (6-ethansulfanyl-quinazolin-4-yl)-(3-
(6,7-dimethoxy-quinazolin-4-yl)-(3-ethynyl-4-fluoro-phenyl)-amine; (6,7-dimethoxy-quinazolin-4-yl)-(3-propyn-1'-yl)-phenyl)-amine; [6,7-bis-(2-methoxy-ethoxy)-quinazolin-4-yl]-(5-ethynyl-2-methyl-phenyl)-amine; [6,7-bis-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethynyl-4-fluoro-phenyl)-amine; [6,7-bis-(2-chloro-ethoxy)-quinazolin-4-yl]-(3-ethynyl-phenyl)-amine; [6-(2-chloro-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; [6,7-bis-(2-acetoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; 2-[4-(3-ethylphenylamino)-7-(2-hydroxy-ethoxy)-quinazolin-6-yloxy]-ethanol; [6-(2-acetoxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; [7-(2-chloro-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; [7-(2-acetoxy-ethoxy)-6-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; 2-[4-(3-ethylphenylamino)-6-(2-hydroxy-ethoxy)-quinazolin-7-yloxy]-ethanol; 2-[4-(3-ethylphenylamino)-7-(2-methoxy-ethoxy)-quinazolin-6-yloxy]-ethanol; 2-[4-(3-ethylphenylamino)-6-(2-methoxy-ethoxy)-quinazolin-7-yloxy]-ethanol; [6-(2-acetoxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-4-yl]-(3-ethylphenyl)-amine; [6-(2-methoxy-ethoxy)-7-(2-methyl-piperazin-1-yl)-ethoxy]-quinazolin-4-yl]-amine; (3-ethynyl-phenyl)-[7-(2-methoxy-ethoxy)-6-(2-morpholin-4-yl)ethoxy]-quinazolin-4-yl]-amine; (6,7-dietoxyquinazolin-l-yl)-(3-ethynylphenyl)-amine; (6,7-dibutoxyquinazolin-1-yl)-(3-ethynylphenyl)-amine; (6,7-diisoproxyquinazolin-1-yl)-(3-ethynylphenyl)-amine; (6,7-dietoxyquinazolin-1-yl)-(3-ethyl-2-methyl-phenyl)-amine; [6,7-bis-(2-methoxy-ethoxy)-quinazolin-1-yl]-(3-ethyl-2-methyl-phenyl)-amine; (3-ethynylphenyl)-[6-(2-hydroxy-ethoxy)-7-(2-methoxy-ethoxy)-quinazolin-1-yl]-amine; [6,7-bis-(2-hydroxy-ethoxy)-quinazolin-1-yl]-(3-ethynylphenyl)-amine; 2-[4-(3-ethylphenylamino)-6-(2-methoxy-ethoxy)-quinazolin-7-yloxy]-ethanol; (6,7-dipropoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6,7-dietoxy-quinazolin-4-yl)-(3-ethyl-5-fluoro-phenyl)-amine; (6,7-dietoxy-quinazolin-4-yl)-(5-ethyl-2-methyl-phenyl)-amine; (6,7-dietoxy-quinazolin-4-yl)-(3-ethyl-4-methyl-phenyl)-amine; (6-aminomethyl-7-methoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-methoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-ethoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-isoproxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine; (6-aminocarbonylmethyl-7-propoxy-quinazolin-4-yl)-(3-ethylphenyl)-amine;
aminocarbonylmethyl-7-methoxy-quinazolin-4-yl)-(3-ethynylphenyl)-amine; (6-aminocarboxylethyl-7-isopropoxy-quinazolin-4-yl)-(3-ethynylphenyl)-amine; and (6-aminocarboxylethyl-7-propoxy-quinazolin-4-yl)-(3-ethynylphenyl)-amine; (6,7-diethoxyquinazolin-1-yl)-(3-ethynylphenyl)-amine; 

(3-ethynylphenyl)-(6-(2-hydroxyethoxy)-7-(2-methoxyethoxy)-quinazolin-1-yl)-amine; [6,7-bis-(2-hydroxyethoxy)-quinazolin-1-yl]-(3-ethynylphenyl)-amine; [6,7-bis-(2-methoxyethoxy)-quinazolin-1-yl]- (3-ethynylphenyl)-amine; (6,7-dimethoxyquinazolin-1-yl)-(3-ethynylphenyl)-amine; (3-ethynylphenyl)-(6-methanesulfonlamino-quinazolin-1-yl)-amine; and (6-amino-quinazolin-1-yl)-(3-ethynylphenyl)-amine.

4. The method of claim 2, wherein the EGFR antagonist of formula I is N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine.

5. The method of claim 4, wherein the EGFR antagonist N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine is in HCl salt form.

7. The method of claim 1, wherein the c-met antagonist is an antibody.

8. The method of claim 7, wherein the antibody is a monovalent antibody.

9. The method of claim 7, wherein the antibody is monovalent and comprises a Fc region, wherein the Fc region comprises a first and a second polypeptide, wherein the first polypeptide comprises the Fc sequence depicted in Figure 7 (SEQ ID NO: 17) and the second polypeptide comprises the sequence depicted in Figure 8 (SEQ ID NO: 18).

10. The method of claim 7, wherein the antibody comprises (a) a first polypeptide comprising a heavy chain variable domain having the sequence:

QVQLQQSGPELVRPGAVKMSCRASGYTFTSYWLHWVQQRQGLEWIGMSDSNS
DTRFNPNFKDKATLNVDRSSNTAYMLLSSLTSADSAVYYCATYGSYVSPLDYWGQG
TSVTSS (SEQ ID NO: 19), CHl sequence depicted in Figure 7 (SEQ ID NO: 16), and the
Fc sequence depicted in Figure 7 (SEQ ID NO: 17); and (b) a second polypeptide comprising
a light chain variable domain having the sequence:
DIMMSQSPSSLTVSVGKEKVTVSCKSSQSLLYTSSQKNYLYAYQKPGQSPKLLIYWA
STRESGVPRFTGSGGTDFTLTISVTADDLAVYYCQYYAYPTFGGKLEIK
(SEQ ID NO:20), and CLl sequence depicted in Figure 7 (SEQ ID NO: 8); and (c) a third
polypeptide comprising the Fc sequence depicted in Figure 8 (SEQ ID NO: 18).

11. The method of claim 1, wherein the cancer is selected from the group consisting
of breast cancer, colorectal cancer, rectal cancer, non-small cell lung cancer, non-Hodgkins
lymphoma, renal cell cancer, prostate cancer, liver cancer, pancreatic cancer, soft-tissue
sarcoma, kaposi's sarcoma, carcinoid carcinoma, head and neck cancer, gastric cancer,
melanoma, ovarian cancer, mesothelioma, and multiple myeloma

12. The method of claim 11, wherein the cancer is non-small cell lung cancer.

13. The method of claim 1, wherein the cancer is not a EGFR antagonist resistant
cancer.

14. The method of claim 1, further comprising administering to the subject a
chemotherapeutic agent.

15. The method of claim 1, wherein the EGFR antagonist is 4-(3'-chloro-4'-fluoroanilino)-7-
methoxy-6-(3-morpholinoproxy)quinazoline.

16. The method of claim 1, wherein the EGFR antagonist is N-[3-chloro-4-[(3-
fluorophenyl)methoxy]phenyl]-6-[5-[[2-(methylsulfonyl)ethyl]amino][methyl]-2-furanyl]-4-
quinazolinamine.

17. The method of claim 1, wherein the EGFR antagonist is 4-(4-bromo-2-fluoroanilino)-6-
methoxy-7-(1-methylpiperidin-4-ylmethoxy)quinazoline.
