(54) Title: HISTONE DEACETYLASE INHIBITORS

(57) Abstract: Provided herein are compounds and methods for inhibiting histone deacetylase ("HDAC") enzymes (e.g., HDAC1, HDAC2, and HDAC3).

HISTONE DEACETYLASE INHIBITORS

TECHNICAL FIELD

[0001] Provided herein are compounds and methods of inhibiting histone deacetylase (“HDAC”) enzymes (e.g., HDAC1, HDAC2, and HDAC3).

BACKGROUND

[0002] To date, 18 HDAC enzymes have been identified in humans and there is increasing evidence that the 18 HDAC enzymes in humans are not redundant in function. HDAC enzymes are classified into three main groups based on their homology to yeast proteins. Class I includes HDAC1, HDAC2, HDAC3, and HDAC8 and have homology to yeast RPD3. HDAC4, HDAC5, HDAC7, and HDAC9 belong to class IIa and have homology to yeast HDAC1. HDAC6 and HDAC10 contain two catalytic sites and are classified as class IIb, whereas HDAC11 has conserved residues in its catalytic center that are shared by both class I and class II deacetylases and is placed in class IV. These HDAC enzymes contain zinc in their catalytic site and are inhibited by compounds like trichostatin A (TSA) and vorinostat [suberoylanilide hydroxamic acid (SAHA)]. Class III HDAC enzymes are known as sirtuins. They have homology to yeast Sir2, require NAD⁺ as cofactor, and do not contain zinc in the catalytic site. In general, HDAC inhibitors of zinc-dependent HDAC enzymes include a Zn-binding group, as well as a surface recognition domain.

[0003] HDAC enzymes are involved in the regulation of a number of cellular processes. Histone acetyltransferases (HATs) and HDAC enzymes acetylate and deacetylate lysine residues on the N termini of histone proteins thereby affecting transcriptional activity. They have also been shown to regulate post-translational acetylation of at least 50 non-histone proteins such as α -tubulin (see for example Kahn, N *et al* Biochem J 409 (2008) 581, Dokmanovic, M., *et al* Mol Cancer Res 5 (2007) 981).

[0004] Altering gene expression through chromatin modification can be accomplished by inhibiting HDAC enzymes. There is evidence that histone acetylation and deacetylation are mechanisms by which transcriptional regulation in a cell – a major event in cell differentiation, proliferation, and apoptosis – is achieved. It has been hypothesized that these effects occur through changes in the structure of chromatin by altering the affinity of histone proteins for coiled DNA in the nucleosome. Hypoacetylation of histone proteins is believed to increase the interaction of the histone with the DNA phosphate backbone. Tighter binding between the histone protein and DNA can render the DNA inaccessible to transcriptional regulatory elements and machinery. HDAC enzymes have been shown to catalyze the

removal of acetyl groups from the ϵ -amino groups of lysine residues present within the N-terminal extension of core histones, thereby leading to hypoacetylation of the histones and blocking of the transcriptional machinery and regulatory elements.

[0005] Inhibition of HDAC, therefore can lead to histone deacetylase-mediated transcriptional derepression of tumor suppressor genes. For example, cells treated in culture with HDAC inhibitors have shown a consistent induction of the kinase inhibitor p21, which plays an important role in cell cycle arrest. HDAC inhibitors are thought to increase the rate of transcription of p21 by propagating the hyperacetylated state of histones in the region of the p21 gene, thereby making the gene accessible to transcriptional machinery. Further, non-histone proteins involved in the regulation of cell death and cell-cycle also undergo lysine acetylation and deacetylation by HDAC enzymes and histone acetyl transferase (HATs).

[0006] This evidence supports the use of HDAC inhibitors in treating various types of cancers. For example, vorinostat (suberoylanilide hydroxamic acid (SAHA)) has been approved by the FDA to treat cutaneous T-cell lymphoma and is being investigated for the treatment of solid and hematological tumors. Further, other HDAC inhibitors are in development for the treatment of acute myelogenous leukemia, Hodgkin's disease, myelodysplastic syndromes and solid tumor cancers.

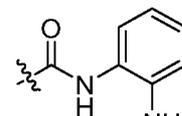

[0007] HDAC inhibitors have also been shown to inhibit pro-inflammatory cytokines, such as those involved in autoimmune and inflammatory disorders (e.g. TNF- α). For example, the HDAC inhibitor MS275 was shown to slow disease progression and joint destruction in collagen-induced arthritis in rat and mouse models. Other HDAC inhibitors have been shown to have efficacy in treating or ameliorating inflammatory disorders or conditions in *in vivo* models or tests for disorders such as Crohn's disease, colitis, and airway inflammation and hyper-responsiveness. HDAC inhibitors have also been shown to ameliorate spinal cord inflammation, demyelination, and neuronal and axonal loss in experimental autoimmune encephalomyelitis (see for example Wanf, L., *et al*, Nat Rev Drug Disc **8** (2009) 969).

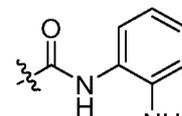

[0008] Triplet repeat expansion in genomic DNA is associated with many neurological conditions (e.g., neurodegenerative and neuromuscular diseases) including myotonic dystrophy, spinal muscular atrophy, fragile X syndrome, Huntington's disease, spinocerebellar ataxias, amyotrophic lateral sclerosis, Kennedy's disease, spinal and bulbar muscular atrophy, Friedreich's ataxia and Alzheimer's disease. Triplet repeat expansion may cause disease by altering gene expression. For example, in Huntington's disease, spinocerebellar ataxias, fragile X syndrome, and myotonic dystrophy, expanded repeats lead

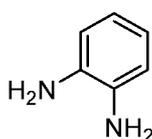

to gene silencing. In Friedreich's ataxia, the DNA abnormality found in 98% of FRDA patients is an unstable hyper-expansion of a GAA triplet repeat in the first intron of the frataxin gene (see Campuzano, et al., *Science* 271:1423 (1996)), which leads to frataxin insufficiency resulting in a progressive spinocerebellar neurodegeneration. Since they can affect transcription and potentially correct transcriptional dysregulation, HDAC inhibitors have been tested and have been shown to positively affect neurodegenerative diseases (see Herman, D., *et al*, *Nat Chem Bio* 2 551 (2006) for Friedreich's ataxia, Thomas, E.A., *et al*, *Proc Natl Acad Sci USA* 105 15564 (2008) for Huntington's disease).

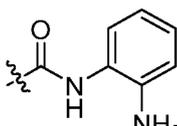

[0009] HDAC inhibitors may also play a role in cognition-related conditions and diseases. It has indeed become increasingly evident that transcription is likely a key element for long-term memory processes (Alberini, C.M., *Physiol Rev* 89 121 (2009)) thus highlighting another role for CNS-penetrant HDAC inhibitors. Although studies have shown that treatment with non-specific HDAC inhibitors such as sodium butyrate can lead to long-term memory formation (Stefanko, D.P., *et al*, *Proc Natl Acad Sci USA* 106 9447 (2009)), little is known about the role of specific isoforms. A limited number of studies have shown that, within class I HDAC enzymes, main target of sodium butyrate, the prototypical inhibitor used in cognition studies, HDAC2 (Guan, J-S., *et al*, *Nature* 459 55 (2009)) and HDAC3 (McQuown, S.C., *et al*, *J Neurosci* 31 764 (2011)) have been shown to regulate memory processes and as such are interesting targets for memory enhancement or extinction in memory-affecting conditions such as, but not limited to, Alzheimer's disease, post-traumatic stress disorder or drug addiction.

[0010] HDAC inhibitors may also be useful to treat infectious disease such as viral infections. For example, treatment of HIV infected cells with HDAC inhibitors and anti-retroviral drugs can eradicate virus from treated cells (Blazkova, J., *et al* *J Infect Dis.* 2012 Sep 1;206(5):765-9; Archin, N.M., *et al* *Nature* 2012 Jul 25, 487(7408):482-5).

[0011] Some prior disclosed HDAC inhibitors include a moiety of , which can metabolize under physiological conditions to provide a metabolite OPD (ortho-

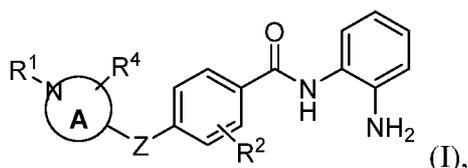

phenylenediamine) . OPD is a toxic material. Thus, the need exists for HDAC

inhibitors comprising a moiety of NH_2 , which, under physiological conditions, produce lower amounts, or substantially no amounts, of OPD.

[0056] The compounds described herein also include pharmaceutically acceptable salts of the compounds disclosed herein. As used herein, the term “pharmaceutically acceptable salt” refers to a salt formed by the addition of a pharmaceutically acceptable acid or base to a compound disclosed herein. As used herein, the phrase “pharmaceutically acceptable” refers to a substance that is acceptable for use in pharmaceutical applications from a toxicological perspective and does not adversely interact with the active ingredient. Pharmaceutically acceptable salts, including mono- and bi- salts, include, but are not limited to, those derived from organic and inorganic acids such as, but not limited to, acetic, lactic, citric, cinnamic, tartaric, succinic, fumaric, maleic, malonic, mandelic, malic, oxalic, propionic, hydrochloric, hydrobromic, phosphoric, nitric, sulfuric, glycolic, pyruvic, methanesulfonic, ethanesulfonic, toluenesulfonic, salicylic, benzoic, and similarly known acceptable acids. Lists of suitable salts are found in Remington's Pharmaceutical Sciences, 17th ed., Mack Publishing Company, Easton, Pa., 1985, p. 1418; Journal of Pharmaceutical Science, 66, 2 (1977); and "Pharmaceutical Salts: Properties, Selection, and Use A Handbook; Wermuth, C. G. and

Stahl, P. H. (eds.) Verlag Helvetica Chimica Acta, Zurich, 2002 [ISBN 3-906390-26-8] each of which is incorporated herein by reference in their entireties.

Methods of Use

[0057] Provided herein are methods of inhibiting one or more HDAC enzymes (e.g., HDAC1 or HDAC2; e.g., HDAC3) or more than one HDAC (e.g., HDAC1 and HDAC2; e.g., HDAC1 and HDAC3; e.g., HDAC2 or HDAC3; e.g., HDAC1, HDAC2, and HDAC3) using a compound or a salt thereof as disclosed herein. In some embodiments, the methods can include contacting one or more HDAC enzymes (e.g., HDAC1 or HDAC2; e.g., HDAC3) in a sample with a compound or a salt thereof as disclosed herein. In other embodiments, the methods can include administering a compound or a salt thereof as disclosed herein to a subject (e.g., a mammal, such as a human).

[0058] A histone deacetylase (HDAC), as described herein, can be any polypeptide having features characteristic of polypeptides that catalyze the removal of the acetyl group (deacetylation) from acetylated target proteins. Features characteristic of HDAC enzymes are known in the art (see, for example, Finnin et al., 1999, *Nature*, 401:188). Thus, an HDAC enzyme can be a polypeptide that represses gene transcription by deacetylating the ϵ -amino groups of conserved lysine residues located at the N-termini of histones, e.g., H3, H4, H2A, and H2B, which form the nucleosome. HDAC enzymes also deacetylate other proteins such as p53, E2F, α -tubulin, and MyoD (see, for example, Annemieke et al., 2003, *Biochem. J.*, 370:737). HDAC enzymes can also be localized to the nucleus and certain HDAC enzymes can be found in both the nucleus and also the cytoplasm.

[0059] Compounds of formula (I) described herein, e.g., compounds of formula (II) or compounds of formula (III), can interact with any HDAC enzyme. In some embodiments, the compounds of formula (I) described herein will have at least about 2-fold (e.g., at least about 5-fold, 10-fold, 15-fold, or 20-fold) greater activity to inhibit one or more class I HDAC enzymes (e.g., HDAC1, HDAC2, or HDAC3) as compared to one or more other HDAC enzymes (e.g., one or more HDAC enzymes of class IIa, IIb, or IV).

[0060] In some embodiments, a compound or a salt thereof as disclosed herein selectively inhibits HDAC3, e.g., selectively inhibits HDAC3 over HDAC1 and HDAC2 (e.g. exhibiting 5-fold or greater selectivity, e.g. exhibiting 25-fold or greater selectivity). While not wishing to be bound by theory, it is believed that HDAC3-selective inhibitors can increase expression of frataxin, and can therefore be useful in the treatment of neurological conditions (e.g., neurological conditions associated with reduced frataxin expression, such as Friedreich's

ataxia). It is also believed that HDAC3 inhibition plays an important role in memory consolidation (McQuown SC *et al*, J Neurosci 31 764 (2011)). Selective inhibitors of HDAC3 provide advantages for treatment of neurological conditions over the use of broad-spectrum HDAC inhibitors by reducing toxicities associated with inhibition of other HDAC enzymes. Such specific HDAC3 inhibitors can provide a higher therapeutic index, resulting in better tolerance by patients during chronic or long-term treatment.

[0061] In some further embodiments, compounds selectively inhibit HDAC1 and/or HDAC2 (e.g exhibiting 5-fold or greater selectivity, e.g. exhibiting 25-fold or greater selectivity). Inhibition of HDAC1 and/or 2 can be useful in treating cancer, or another disease as disclosed herein.

[0062] In some embodiments, a compound or a salt thereof as disclosed herein exhibits enhanced brain penetration. For example, brain/plasma ratios of greater than about 0.25 (e.g., greater than about 0.50, greater than about 1.0, greater than about 1.5, or greater than about 2.0) are observed when rats, mice, dogs, or monkeys are dosed with some of the compounds disclosed herein. In some embodiments, a compound or a salt thereof as disclosed herein selectively inhibits HDAC3, e.g., selectively inhibits HDAC3 over HDAC1 and HDAC2 (e.g. exhibiting 5-fold or greater selectivity, e.g. exhibiting 25-fold or greater selectivity) and exhibits enhanced brain penetration. In some embodiments, a compound described herein selectively inhibits HDAC1 and/or HDAC2, e.g., selectively inhibit HDAC1 and/or HDAC2 over HDAC3 (e.g exhibiting 5-fold or greater selectivity, e.g. exhibiting 25-fold or greater selectivity) and exhibits enhanced brain penetration.

[0063] Compounds with enhanced brain penetration are suitable for therapies targeting the brain (e.g., neurological conditions such as Friedreich's ataxia, myotonic dystrophy, spinal muscular atrophy, fragile X syndrome, Huntington's disease, spinocerebellar ataxia, Kennedy's disease, amyotrophic lateral sclerosis, spinal and bulbar muscular atrophy, and Alzheimer's disease; a memory impairment condition, frontotemporal dementia; post-traumatic stress disorder; a drug addiction).

[0064] Provided herein are methods of treating a disease or disorder mediated by HDAC in a subject (e.g., a mammal, such as a human) in need thereof, which include administering a compound or a salt thereof as disclosed herein to the subject.

[0065] Further provided herein are methods of preventing a disease or disorder mediated by HDAC in a subject (e.g., a mammal, such as a human) in need thereof. Prevention can

include delaying the onset of or reducing the risk of developing, a disease, disorder, or condition or symptoms thereof.

Synthesis of Compounds 78, 81, 85, 87-93, 110-120, 122, 134, 135, 140-142 and 170

[00260] Synthesis of Compounds 78, 81, 85, 87-93, 110-120, 122, 134, 135, 140-142 and 170 are generally described in the following Scheme D:

Scheme D

[00261] General procedure for Reductive Amination: *Procedure A*: To a stirred solution of the amino compound (1 eq) and the corresponding aldehyde (1.2 eq) in DCM was added acetic acid (6 eq) and sodium triacetoxyborohydride (STAB) (3 eq) at room temperature. After stirring the reaction mixture at ambient temperature overnight, the reaction progress was monitored by TLC and LCMS. After completion of reaction, the reaction mixture was partitioned between DCM and water. The organic layers were separated, washed with water and brine, dried over Na₂SO₄ and evaporated to get the crude product which was purified by silica gel column chromatography to afford the desired compound.

[00262] *Procedure B*: To a stirred solution of the amino compound (1 eq) and the corresponding aldehyde (1.2 eq) in DCE/DCM was added titanium tetra-isopropoxide (Ti(O-

i-Pr)₄) (1.5 eq), AcOH (1.5 eq) at room temperature. After 5 min, STAB (1.5 eq) was added and the mixture was heated at 60 °C for 12 h. The reaction progress was monitored by TLC and LCMS. After completion of reaction, the reaction mixture was diluted with DCM and the resulting mixture was filtered over a pad of celite. The filtrate was concentrated and the resulting residue was purified by silica gel column chromatography to provide the desired compound.

[00263] General procedure for Ester Hydrolysis: To stirred solution of the ester compound in methanol: water (1:1) was added NaOH (1.5 eq) at room temperature. The above mixture was heated to 90 °C for 5h. The progress of the reaction was monitored by TLC. After completion of reaction, the reaction mixture was concentrated and the resulting residue was washed with diethyl ether followed by treatment with water. [00264] General procedure for Amide Coupling: To a stirred solution of the acid compound (1 eq) and the corresponding amino compound (1.1 eq) in ACN was added pyridine (5eq) and HATU (1.5 eq) at room temperature. After stirring the reaction mixture at 80 °C for overnight, the reaction progress was monitored by TLC and LCMS. After completion, the reaction mixture was concentrated and resulting residue was partitioned between water and ethyl acetate. The organic layers were separated, washed with water and 1% HCl to remove traces of pyridine, dried over Na₂SO₄ and concentrated. The crude residue was purified by silica gel column chromatography to provide the desired compound.

[00265] General procedure for Boc-Deprotection: To a stirred solution of the Boc compound (1 eq) in 1,4-dioxane was added 4M HCl in dioxane at room temperature. After completion of reaction, the reaction mixture was concentrated and the resulting residue was triturated with *n*-pentane and dried under vacuum to give desired compound.

The reaction mixture was heated at 80 °C for 5 h to 30 h. The progress of reaction was monitored by TLC. After completion, the reaction mixture was poured into ice-water and extracted with ethyl acetate. The combined organic extracts were washed with water, brine, dried over anhydrous Na₂SO₄, filtered and concentrated under reduced pressure to provide a crude residue which was purified by silica gel column chromatography.

[00267] *Procedure B:* To a solution of the amino compound (1 eq) in 5 vol of ethanol was added TEA (3 eq) followed by 2, 2-dimethyloxirane (2.5 eq) at room temperature and the reaction mixture was heated at 90 °C for 4h. The progress of reaction was monitored by TLC. After completion, the reaction mixture was allowed to cool, concentrated to give a crude compound which was purified by Combiflash chromatography/silica gel column chromatography.

[00268] General procedure for Cbz Deprotection: To a stirred solution of the Cbz compound (1 eq) in methanol/4M HCl in MeOH, 10% Pd/C (10% w/w of substrate) was added and the reaction mixture was stirred under hydrogen atmosphere (balloon pressure) at room temperature for 3 h. The progress of the reaction was monitored by TLC. After completion, the reaction mixture was filtered through a pad of celite, the filtrate was evaporated under reduced pressure and the resulting residue was triturated with diethyl ether and n-pentane and then dried under vacuum to afford the title compound. Some of the final compounds were purified by Prep-HPLC.

HDAC1 (BPS Bioscience, San Diego, CA, #50051), HDAC2 (BPS Bioscience, #50053), or HDAC3/NcoR2 (BPS Bioscience, #50003) at concentrations of 1.25, 1.32, and 0.167 $\mu\text{g/mL}$, respectively. Following pre-incubation, Fluor-de-LysTM substrate (Enzo Life Sciences, Plymouth Meeting, PA, BML-KI104-0050) is added to a final concentration of 10 μM and plates are further incubated for 30 minutes at room temperature. The enzymatic reaction is stopped by addition of Trichostatin A (Sigma-Aldrich, St Louis, MO, #T8552, final concentration: 100 nM) and trypsin (MP Biomedicals, Solon, OH, #02101179) are added to reach a final concentration of 100 $\mu\text{g/mL}$. After a 15 minute incubation at room temperature, fluorescence is recorded using a Spectramax M2 fluorometer (Molecular Devices, Sunnyvale, CA) with excitation at 365nm and emission at 460 nm. IC₅₀ values are calculated by using a sigmoidal dose-response (variable slope) equation in GraphPad Prism® 5 for Windows (GraphPad Software, La Jolla, CA).

Acid stability determination

[00466] A 100 μM solution of test compound is prepared by dilution of a 10 mM DMSO stock solution in a 0.01 M solution of HCl in deionized water. Immediately after mixing, an aliquot (100 μL) is sampled and analyzed by HPLC/UV. The area under the compound peak is determined and used as the time zero reference point. The remainder of the acid sample is incubated at 50 °C and samples were taken after 2, 4, and 24 or 30 hours of incubation. These are analyzed by the same HPLC/UV method and the area of the peak corresponding to the test compound is measured. Percent remaining at a given time point is then calculated as the ratio of the area under the peak after incubation to that at time zero times 100. In those embodiments where a 30 hour time point is recorded, the percent remaining at 24 hours is obtained by interpolation of the percent remaining versus time curve assuming a unimolecular process, i.e. a monoexponential decay.

Brain penetration studies

[00467] Test compounds are prepared at either 0.5 mg/ml or 5 mg/ml in 30% hydroxypropyl- β -cyclodextrin, 100 mM sodium acetate pH 5.5, 5% DMSO. Rats or C57/BL6/J mice are dosed s.c. at 5 mg/kg or 50 mg/kg, or i.v. at 5 mg/kg. Animals are euthanized at pre-dose, 5, 15, 30 min, 1, 2 and 4 hours post-dose and plasma and brain obtained. Three animals per dose per time points are used. The levels of compound in the plasma and brain are determined by standard LC/MS/MS methods. Brain/plasma ratio (BPR) is calculated as the ratio of the C_{max}(brain)/C_{max}(plasma).

In-cell deacetylase inhibition assay (DAC assay)

[00468] GM 15850(lymphoblastoid cells line) cells are seeded in 96-well plates at an appropriate density (100,000 cells/well) in 90 μ L RPMI1640 medium containing 10% v/v fetal bovine serum (FBS), 1% v/v penicillin/streptomycin, and 1% v/v L-glutamine. Compound dilutions are made in 100% DMSO followed by parallel dilution in media with 2% DMSO. 10 μ L of the compound dilutions are added to the cells to achieve the desired concentrations. The final concentration of DMSO in each well is 0.2%. The cells are incubated for 4h at 37 °C with 5% CO₂. After incubation, the cells are centrifuged down and the supernatant removed. The cell pellets are washed with 100 μ L phosphate-buffered saline (PBS) and then lysed with 45 μ L lysis buffer (HDAC assay buffer at pH 8.0 (25 mM Tris/HCl, 137 mM NaCl, 2.7 mM KCl, 1 mM MgCl₂) + 1% v/v Igepal CA-630). To initiate the reaction, the HDAC substrate KI-104 (Enzo Life Sciences, Farmingdale, NY) is added to a final concentration of 50 μ M. The reaction is stopped after 30 min incubation by addition of 50 μ L developer (6 mg/mL trypsin in HDAC assay buffer). The reaction is allowed to develop for 30 min at room temperature and the fluorescence signal is detected using a fluorometer (Spectramax M2, Molecular Devices, Sunnyvale, CA) with excitation and emission wavelengths of 360 nm and 470 nm respectively. The data are fitted to a sigmoidal dose response equation with variable slope in GraphPad Prism 5.0 (GraphPad Software, La Jolla, CA) to determine IC₅₀. Bottom and top of the curve are fixed to the average fluorescence response of control wells with no cells and cells but no compound respectively.

Cell proliferation assay

[00469] HCT116 cells (5000 cells/well) in 80 μ L McCoy's 5A medium containing 10% v/v FBS, 1% v/v penicillin/streptomycin and 1% v/v L-glutamine are incubated in 96-well plates with compounds at various concentrations for 72h at 37 °C in a 5% CO₂ atmosphere. The compound dilutions are made in 100% DMSO followed by parallel dilutions in media. The final concentration of DMSO in each well is 0.05%. After 72h, 20 μ L of Cell titer 96 aqueous one solution (Promega Corporation, Madison, WI) are added to the cells and the plate is incubated at 37 °C for another 4h. The absorbance at 490nm is then recorded on a 96-well plate reader (Spectramax M2, Molecular Devices, Sunnyvale, CA). Data analysis is performed in Microsoft Excel (Microsoft Corp, Redmond, WA). $(O.D. \text{ sample} - \text{average } O.D. \text{ positive control}) / (\text{average } O.D. \text{ negative control} - \text{average } O.D. \text{ positive control}) * 100$, where O.D. is the measured absorbance, O.D. positive control is the absorbance from cells incubated with trichostatin A at 5 μ M and O.D. negative control is the absorbance measured from cells incubated without any compound, is plotted against compound concentration and

an IC₅₀ is determined by graphical interpolation of the concentration required for 50% inhibition of cell growth.

Protocol for compound stability in hepatocytes

[00472] To assess the stability and metabolism of RGFP compounds in hepatocytes. This assay was designed to evaluate the metabolism of RGFP compounds, following their incubation with human, monkey, dog and rat hepatocytes by monitoring either parent drug disappearance or metabolite appearance using HPLC.

[00473] Equipment: Applied Biosystem Triple Quadrupole LC/MS/MS; Ice bucket, timer; 96 well plates; Falcon, Cat# 353072; 96 well plates shaker; Various pipettes: 10 μ L, 20 μ L, 200 μ L, and 1000 μ L; Test tubes: Catalog # VWR 47729-572, 13x 100 mm

[00474] Procedure: Turn on the water-bath heater to 37°C. Take out the KHB buffer and make sure it is at room temp before use. Prepare 2.5 mM concentration of RGFP compound in DMSO stock. Add 10 μ L of above DMSO stock to 2490 μ L KHB buffer; final concentration of RGFP compound will be 10 μ M. Pre-warm 45ml InVitro HT Medium to 37 °C in a sterile 50 mL conical tube. Add 1.0 mL Torpedo Antibiotic Mix per 45 mL InVitro HT medium. Transfer 13 mL of warm HT medium with Antibiotic Mix into a 15 mL conical tube. Carefully remove the hepatocyte vials from liquid nitrogen (liquid phase). Immediately immerse the vial into a 37 °C water bath. Shake gently until the ice melts entirely. Do not keep the cells in 37 °C water bath longer than necessary. Immediately empty contents of the vial into 13 mL of pre-warmed InVitro HT Medium with antibiotics. Rinse the

vial with the HT media that you have just transferred the hepatocytes to, in order to ensure complete transfer. Centrifuge the cell suspension at 600 RPM for 5 minutes at room temperature. Discard the supernatant by either pouring in one motion (do not pour partially and re-invert centrifuge tube) or aspirating using a vacuum pump. Add 1.0 mL of KHB (at room temperature) buffer to the tube of hepatocyte pellet. Loosen the cell pellet by gently swirling the centrifuge tube. Transfer 100 μ L of above solution to a different tube and add 900 μ L of KHB buffer to count the cells. Determine the total cell count and the number of viable cells using the Trypan Blue exclusion method. Once the cell count is obtained, multiply the number by 10 (attributing to the dilution factor). Now add required volume of KHB buffer to the tube containing hepatocytes such that the final count will be 2 million cells/mL. Dispense 50 μ L of 2 million cells/ml to a 96 well plate and then add 50 μ L of DMSO stock to respective wells (such that, the concentration of RGFP compounds is 5 μ M and number of cells are 100000 in each well). Place the plates on a shaker in a 37 °C incubator with 5% CO₂. Separate plates for each time point are advisable (Time points: 0h, 1h, 2h, and 6 h). After each time point, add 100 μ L of quenching solution.

[00475] Quenching solution is an acetonitrile solution containing RGFP531 (10 μ M) internal standard, 0.1% formic acid and phenylglyoxol (400 μ M). The formic acid and phenylglyoxal is used for the identification and quantification of OPD as mentioned above. Pipette up and down a few times to ensure a complete stop of reaction. Transfer all the solution into a 1.5 mL tube, vortex thoroughly, and centrifuge at 14000 RPM at 4 °C for 5 minutes to precipitate cell debris. Transfer the 150 μ L of supernatant to vials for analysis using HPLC.

Effect of compounds on long term memory for object recognition

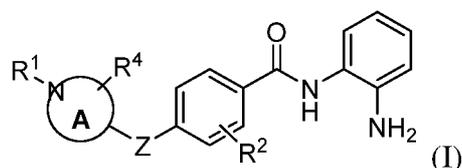

[00476] Rats or C57BL/6J male mice are handled 1-2 min for 5 days and habituated to the experimental apparatus 5 min a day for 4 consecutive days in the absence of objects. During the training trial, rats or mice are placed in the experimental apparatus with two identical objects and allowed to explore these objects for 3 min, which does not result in short- or long-term memory (Stefanko, et al., 2009). Immediately following training, rats or mice receive subcutaneous injections of either vehicle (20% glycerol, 20% PEG 400, 20% propylene glycol, and 100 mM sodium acetate, pH 5.4), reference compound 1, RGFP109, class I HDAC inhibitor, (3, 10, 30 mg/kg), reference compound 2, RGFP136 (3, 10, 30 mg/kg), or a test compound disclosed herein (3, 10, 30 mg/kg). 24-h later rats or mice are tested for memory retention (5 min) using the object recognition memory task (ORM), in which a familiar object is replaced with a novel one. All training and testing trials are

videotaped and analyzed by individuals blind to the treatment condition and the genotype of subjects. A rat or mouse is scored as exploring an object when its head was oriented toward the object within a distance of 1 cm or when the nose is touching the object. The relative exploration time is recorded and expressed by a discrimination index [DI = $(t_{\text{novel}} - t_{\text{familiar}})/(t_{\text{novel}} + t_{\text{familiar}}) \times 100$].

[00477] A number of embodiments have been described. Nevertheless, it will be understood that various modifications may be made without departing from the spirit and scope of the disclosure. Accordingly, other embodiments are within the scope of the following claims.
