(54) **DISPOSITIF D'ACCES CHIRURGICAL MANUEL**

(54) **SURGICAL HAND ACCESS DEVICE**

(57) L'invention porte sur un dispositif (10) d'accès manuel comprenant un manchon (11) extérieur, un manchon (12) intérieur et un rebord (13). L'extrémité proximale du dispositif (10) est fermée hermétiquement par le manchon (11) extérieur gonflé par un gaz, et l'extrémité distale est hermétiquement fermée par les parois du manchon (12) intérieur, replié dans le corps du patient, par la pression du gaz agissant sur les parois du manchon (12) intérieur. Le dispositif (10) est doté d'un anneau (15) interne fixé à un tablier (16) contre le manchon (12) intérieur. L'anneau (15) interne fixe le dispositif sous la paroi abdominale du patient et le tablier (16) sert d'élément de protection des lésions autour du site d'incision du corps du patient.

(57) The hand access device (10) comprises an outer sleeve (11) an inner sleeve (12) and a flange (13). The proximal end of the device (10) is sealed by the outer sleeve (11) being inflated by gas and the distal end is sealed by the walls of the inner sleeve (12) being collapsed by gas pressure within a patient's body cavity acting on the walls of the inner sleeve (12). The device (10) is fitted with an internal ring (15) attached with an apron (16) to the inner sleeve (12). The internal ring (15) anchors the device below the abdominal wall of the patient and the apron (16) acts as a wound protector around the site of the incision in the patient's body.

(54) Title: SURGICAL HAND ACCESS DEVICE (57) Abstract The hand access device (10) comprises an outer sleeve (11) an inner sleeve (12) and a flange (13). The proximal end of the device (10) is sealed by the outer sleeve (11) being inflated by gas and the distal end is sealed by the walls of the inner sleeve (12) being collapsed by gas pressure within a patient's body cavity acting on the walls of the inner sleeve (12). The device (10) is fitted with an internal ring (15) attached with an apron (16) to the inner sleeve (12). The internal ring (15) anchors the device below the abdominal wall of the patient and the apron (16) acts as a wound protector around the site of the incision in the patient's body. 		

SURGICAL HAND ACCESS DEVICE

The present invention relates to a surgical hand access device, in particular to improvements to a surgical hand access device for minimally invasive surgery.

5

In minimally invasive surgery gas is generally introduced into a patient's peritoneal cavity to cause pneumoperitoneum. Hand assisted laproscopic surgery (HALS) is a refined form of minimally invasive surgery where a small incision is made in the patient's abdomen and a hand access device is inserted into the incision. Using the
10 hand access device a surgeon can insert his hand into the patient's abdomen and can perform many procedures that cannot be accomplished by standard minimally invasive techniques.

One particularly effective hand access device is that disclosed in our European Patent
15 Specification No. 0 744 922. That device comprises a sleeve having an entry opening located at a proximal end of the sleeve and an exit opening located at a distal end for insertion into an incision made in a patient's body. The sleeve at the exit opening is collapsible by gas pressure within the abdominal cavity of the patient at or adjacent the distal edges of the sleeve. A taut valve, is also provided at the distal edges of the
20 sleeve to reinforce the seal and to anchor the device on the patients body when the inflatable chambers of the device outside the patient's body are inflated by gas pressure. This device is a very effective and simple hand access device.

The present invention provides a hand access port device for use in minimally invasive
25 surgery comprising a flexible tube having an entry opening at a proximal end and an exit opening at a distal end, exit opening sealing means which in use are effected by gas pressure within the abdominal cavity of a patient and sealing means for sealing the entry opening while allowing access for a surgeon's hand or a surgical instrument, an anchoring element, separate from and not attached to the exit opening sealing means,
30 is provided to anchor the device against the abdominal wall of the patient's body

AMENDED SHEET

cavity, characterised in that the flexible tube comprises an outer sleeve and an inner sleeve which are joined only at the proximal end of the device with a flange being provided at a distal end of the outer sleeve, the flange being mountable on the patient's abdomen around the site of an incision.

5

Preferably, the anchoring element is a deformable ring which may be inserted through the incision in the patient's body and reverts to its original shape within the patient's body to anchor the device.

- 10 Conveniently, an apron is attached to the outer wall of the inner sleeve with the anchoring element being located at the distal end of the apron element.

Preferably, the apron is adapted to be used as a wound protector whereby the outer wall of the apron contacts the surfaces of the incision.

15

Advantageously, the exit sealing means comprises a cuff valve and the cuff valve comprises a pair of semi rigid strips, each strip being housed in one of a pair of opposed pockets formed at the distal end of the inner sleeve.

- 20 Conveniently, the distal end of the outer sleeve is provided with an inflatable toroidal section for contact with the patient's skin.

Advantageously, a third sleeve element is provided within the inner sleeve to act as an intermediate valve about a surgeon's hand between the entry sealing means and the
25 exit sealing means.

Additionally, the anchor element includes a ring element mountable externally of the patient's body.

AMENDED SHEET

The device is generally made from flexible, impermeable, biocompatible medically sterile, plastics/polymeric materials.

5 The invention will hereinafter be more particularly described with reference to the accompany drawings which show by way of example only, a number of embodiments according to the invention. In the drawings: -

10 Figure 1 is a side view of a first embodiment of surgical hand access device according to the invention;

Figure 2 is a side view of a second embodiment of surgical hand access device according to the invention, having a longer inner sleeve than the first embodiment;

15 Figures 3 and 4 are side views respectively of third and fourth embodiments of a surgical hand access device;

Figures 5 and 6 are side views respectively of fifth and sixth embodiments of a hand access device;

20 Figure 7 is a side view of a seventh embodiment of a hand access device and Figure 7a is a side view of a modification of the seventh embodiment;

Figures 8 and 9 are side views respectively of an eighth and ninth embodiment of a hand access device;

25 Figure 10 is a side view of a tenth embodiment of a hand access device according to the invention and Figure 10a is a side view of an outer sleeve.

30 Figure 11 and 11a are a side view respectively of an eleventh embodiment of hand access device according to the invention and the outer sleeve;

Figure 12 is a perspective view of the eleventh embodiment in position on a patient's abdominal wall;

Figure 13 is a perspective view of one end of a cuff valve which can be used in all the
5 above embodiments;

Figure 14 is a perspective view of a hinge and Figure 14a is a perspective view of the hinge applied to the cuff;

10 Figure 15 is a perspective view of an alternative hinge and Figure 15a is a perspective view of the alternative hinge applied to the cuff.

Referring to the drawings, and initially to Figure 1 the hand access device 10 comprises an outer sleeve 11 and an inner sleeve 12, a flange 13, an insufflation valve 14. It is operated
15 in the same manner as our earlier device as described in the above mentioned European patents specification. The device 10 however is fitted with an internal ring 15 which is attached with an apron 16 to the inner sleeve 12 adjacent to the flange 13 below a feather valve 17. The device has no side welds or cross welds and accordingly as the device is inflated with gas the outer sleeve 11 expands and extends upwards and outwards drawing
20 the inner sleeve 12, the attached apron 16 and flexible internal ring 15 upwards. The effect of the upwards movement is to cause the internal ring 15 to act as an anchor below the abdominal wall and for the further purpose of the apron 16 acting as an additional protective barrier between the incision site and the tissue being operated on by the surgeon. Additionally, the drawing up of the apron 16 and internal ring 15 acts to retract the incision
25 site helping to create a wider incision lumen through which a surgeon can insert a hand and forearm. A cuff valve 18 is positioned below the ring 15 and comprises two strips of 1 mm VIVAK 15 mm wide enclosed in a SARANEX pocket at the distal end of the inner sleeve 12. (VIVAK and SARANEX are registered trade marks).

30 The second embodiment 20 is generally similar to the first embodiment 10 except that the inner sleeve 22 is longer so as to better accommodate the distance from the fingertips to the forearm to allow a seal around the forearm before breaking the seal at the distal valve.

The third embodiment device 30 comprises two rings, an internal ring 35 and an external ring 36. A taut valve 38 is applied at the distal end of the inner sleeve 32.

- 5 The fourth embodiment device 40 has a reduced outer sleeve 41 and flame 43. A reinforced taut valve 48 is provided at the distal end of the inner sleeve 42.

The fifth embodiment 50 has a reduced outer sleeve 51 and an internal ring 55. The outer sleeve is reduced in height by shortening the length of the side welds 52 that connect the
10 inner sleeve 53 to the outer sleeve 51. There are no cross welds connecting the inner sleeve 53 and outer sleeve 51. The effect of this is to allow the outer sleeve 51 to move to a greater extent up and down relative to the inner sleeve 53.

In addition the outer sleeve 51 is designed to have extra material at the lower section. The
15 extra material is connected to a flange according to the invention or other conformable flexible material 57. The inclusion of the extra material at the lower section of the outer sleeve allows the lower section to inflate to a greater extent than the upper section. As gas is induced into the device causing the outer sleeve to inflate, the inner sleeve 53 with the apron 56 and internal ring 55 attached is drawn up. The ability of the outer sleeve 51 to
20 draw the inner sleeve 53 up is limited by the internal ring 55 and this limitation causes a ballooning effect of the extra outer sleeve 51 material. The ballooning effect has the result, the external flange 57 and inflated toroid 54 combined with the apron 56 and ring 55 anchored internally acts to create a very effective seal around the incision to the gas and further acts as an aseptic seal to the external air. The inner sleeve 53 acts as an integral
25 wound protector.

The taut valve 58 has struts inside the wings 59. The inner sleeve 52 has side welds which prevent inversion of the inner sleeve. The embodiment 60 has a larger outer sleeve 61, an internal ring 65 and a taut valve 68.

30

The embodiment 70 has an internal ring 75 and an external ring 76. In Figure 7a the cross section of the internal ring is 8 mm as opposed to 6 mm. The internal ring restricts

movement of the taut valve 78 and therefore makes it much easier to pass the hand fully through the valve as far as the forearm.

The embodiment 80 has two rings 85 and 86 and flat weld drapes 83 and 84 as has the
5 embodiment 90 with two rings 95 and 96. The external ring 96 is closer to the flange 97. The anchor rings 95, 96 give very good results with the internal ring taking up most of tenting force. The flexible outer sleeve 91 allows movement of the surgeon's arm without putting strain on any part of the device.

10 In the tenth embodiment 100, the length of inner sleeve 102 has been increased by 50 mm to allow the taut valve 108 to come up against the internal ring 105. Both of the rings 105 and 106 are made from polyurethane. On inflation of the device there is no gas loss and the tenting force acts on the internal ring. The outer sleeve 101 is very flexible but side
15 welds prevent it from inverting at its proximal end. The inner 102 holds quite taut between its proximal end and the internal ring. A feather valve 103 is used to form a seal about a surgeon's arm.

The eleventh embodiment 110 is similar to embodiment 100 except the outer sleeve 111 is configured in a straight line. The sleeve 110 is shown in Figures 11 and 12. The external
20 ring when in position on a patient and the internal ring 115 downloads the force from the flange 113 and protects the taut valve from deflating.

Modifications to the taut valve 130 are shown in Figures 13 to 15a with the use of hinges
140 and 150.

25

It will of course be understood that the invention is not limited to the specific details described herein, which are given by way of example only, and that various modifications and alterations are possible within the scope of the invention as defined in the appended claims.

CLAIMS:

1. A hand access port device (10) for use in minimally invasive surgery comprising a flexible tube (11,12) having an entry opening at a proximal end and an exit opening at a distal end, exit opening sealing means which in use are effected by gas pressure within the abdominal cavity of a patient and sealing means for sealing the entry opening while allowing access for a surgeon's hand or a surgical instrument, an anchoring element, separate from and not attached to the exit opening sealing means, is provided to anchor the device (10) against the abdominal wall of the patient's body cavity, characterised in that the flexible tube comprises an outer sleeve (11) and an inner sleeve (12) which are joined only at the proximal end of the device with a flange (13) being provided at a distal end of the outer sleeve (11), the flange (13) being mountable on the patient's abdomen around the site of an incision.
2. A hand access port device (10) as claimed in Claim 1, in which the anchoring element is a deformable ring (15) which may be inserted through the incision in the patient's body and reverts to its original shape within the patient's body to anchor the device.
3. A hand access port device (10) as claimed in Claim 3, in which an apron (16) is attached to the outer wall of the inner sleeve (12) with the anchoring element being located at the distal end of the apron element (16).
4. A hand access port device (10) as claimed in Claim 4, in which the apron (16) is adapted to be used as a wound protector whereby the outer wall of the apron contacts the surfaces of the incision.
5. A hand access port device (10) as claimed in Claim 3, in which the distal end of the outer sleeve (11) is provided with an inflatable toroidal section (54) for contact with the patient's skin.

AMENDED SHEET

6. A hand access device (10) as claimed in any one of the preceding claims, in which the exit sealing means comprises a cuff valve (18).

7. A hand access device (10) as claimed in Claim 7, in which the cuff valve (18)
5 comprises a pair of semi rigid strips, each strip being housed in one of a pair of opposed pockets formed at the distal end of the inner sleeve (12).

8. A hand access port device (10) as claimed in Claim 3, in which a third sleeve element is provided within the inner sleeve to act as an intermediate valve about a surgeon's hand
10 between the entry sealing means and the exit sealing means.

9. A hand access port device (10) as claimed in any one of the preceding claims, in which the anchor element includes a ring element mountable externally of the patient's body.

15

10. A hand access port device (10) as claimed in any one of the preceding claims in which the device is made from flexible, impermeable, biocompatible medically sterile, plastics/polymeric materials.
