(54) Title: IMPROVED PROCESSEIBILITY AND LACING RESISTANCE WHEN SILANIZED PIGMENTS ARE INCORPORATED IN POLYMERS

(57) Abstract

    White-pigmented polymers (particularly, polyolefins such as polyethylene) containing white pigments treated with at least one silane or a mixture of at least one silane and at least one polysiloxane are disclosed to improve processibility in compounding and improve performance properties such as lacing resistance in a polymeric matrix.

TITLE
IMPROVED PROCESSIBILITY AND LACING RESISTANCE WHEN
SILANIZED PIGMENTS ARE INCORPORATED IN POLYMERS

BACKGROUND OF THE INVENTION
The present invention relates to white-pigmented polymers
(particularly, polyolefins such as polyethylene) containing white pigments treated
with an organosilicon compound to improve processibility in compounding and
improve performance properties such as lacing resistance in a polyolefin matrix.

Treatment of TiO₂ pigment with organosilicon compounds to improve
dispersibility in a polymer matrix is well known in the art. For example, U.S.
Patents 4,061,503 and 4,151,154 disclose enhanced dispersibility of TiO₂ in paints
and plastics. Therein, the TiO₂ is surface treated with a silane possessing at least
two hydrolyzable groups bonded to silicon and an organic group containing a
polyalkylene oxide group.

In addition, U.S. Patent 4,810,305 discloses a modified hydrophobic
pigment or filler containing 0.05 to 10 weight % of an organopolysiloxane, with
improved dispersibility in synthetic resins.

However, deficiencies in the prior art include, but are not limited to,
(1) unacceptable processibility, i.e., dispersibility of TiO₂ pigment in a polymeric
matrix at slow rates; and (2) lacing, i.e., development of imperfections in a
polyolefin matrix. Lacing occurs as a result of volatiles released from the pigment
during high temperature polyolefin fabrication processes. Lacing may also be
attributable to TiO₂ concentrates picking up moisture. A further disadvantage is
that higher loadings of TiO₂ pigment in a polymer concentrate result in slower
processing rates.

It has been found that the above combined disadvantages of the prior
art can be overcome by the present invention.

SUMMARY OF THE INVENTION
In accordance with this invention there is provided a polymeric matrix
comprising polymer and about 0.01 to about 87 % by weight silanized TiO₂
pigment, based on the weight of the polymeric matrix, wherein the silanized TiO₂
pigment has a coating of about 0.1 to about 5 % by weight, based on the weight of
silanized TiO₂ pigment, of an organosilicon compound selected from at least one silane, or a mixture of at least one silane and at least one polysiloxane. It has been found that the silanized pigmentary TiO₂ provides a unique combination of enhanced processibility in a polymeric matrix having higher TiO₂ loadings, and improved end use performance properties such as lacing resistance in a polyolefin matrix at TiO₂ concentrations ranging from about 0.2 to about 20 % by weight, based on the weight of the polyolefin matrix.

DETAILED DESCRIPTION

The TiO₂ pigments useful in the present invention generally are in the rutile or anatase crystalline form. It is commonly made by either a chloride process or a sulfate process. TiCl₄ is oxidized to TiO₂ particles in the chloride process. Sulfuric acid and ore containing titanium are dissolved, and the resulting solution goes through a series of steps to yield TiO₂, in the sulfate process. Both the sulfate and chloride processes are described in greater detail in "The Pigment Handbook", Vol. 1, 2nd Ed., John Wiley & Sons, NY (1988), the teachings of which are incorporated herein by reference. The optimum average particle size can range from about 0.005 to about 1 micron. The TiO₂ pigments may also contain ingredients added thereto to further improve dispersibility characteristics or other properties such as durability. Thus, by way of example, but not limited thereto, the pigment may contain additives and/or inorganic oxides, such as aluminum, silicon or tin as well as triethanolamine, trimethylolpropane, phosphates, etc.

"Silanized" TiO₂ is defined herein to refer to TiO₂ treated with either at least one silane, or a mixture of at least one silane and at least one polysiloxane (collectively referred to herein as organosilicon compounds).

Suitable silanes have the formula:

\[ R_xSi(R')_{4-x} \]

wherein

R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group
having at least 1 to about 20 carbon atoms;
R’ is a hydrolyzable group such as an alkoxy, halogen, acetoxy or hydroxy or mixtures thereof; and

\[ x = 1 \text{ to } 3. \]

For example, silanes useful in carrying out the invention include

octyltriethoxysilane, nonyltriethoxysilane, decyltriethoxysilane,
dodecyltriethoxysilane, tridecyltriethoxysilane, tetradecyltriethoxysilane,
pentadecyltriethoxysilane, hexadecyltriethoxysilane, heptadecyltriethoxysilane and
octadecyltriethoxysilane. Additional examples of silanes include, R = 8-18 carbon
atoms; R' = chloro, methoxy, hydroxy or mixtures thereof; and x = 1 to 3. Preferred
silanes are R = 8-18 carbon atoms; R' = ethoxy; and x = 1 to 3. The R = 8-18 carbon
atoms is preferred for enhanced processibility. R' = ethoxy is preferred for ease of
handling. Surprisingly, lower chain alkyl silanes resulted in longer processing times.
Mixtures of silanes are contemplated equivalents. Weight content of the silane,
based on total silanized pigments TiO₂ is typically about 0.1 to about 5 weight %,
preferably about 0.5 to about 1.5 weight %. In excess of 5 weight % may be used
but no particular advantage is observed.

In an alternative embodiment, a mixture of at least one silane with at
least one polysiloxane is useful in carrying out the invention. Suitable polysiloxanes
have the formula:

\[ \left( \frac{R_nSiO_{4-n}m}{2} \right) \]

wherein
R is organic or inorganic groups;
n = 0-3; and
m ≥ 2.

For example, polydimethylsiloxane (PDMS), vinyl phenylmethyl terminated
dimethyl siloxanes, divinylmethyl terminated polydimethyl siloxane and the like are
suitable polysiloxanes. PDMS is a preferred polysiloxane. The silane useful in the
mixture may be the silane described above with R = 1-8 carbon atoms, R' = alkoxy
and x = 1 preferred. Weight content of the silane and polysiloxane, based on total
silanized pigments TiO₂, is about 0.1 to about 5.0 weight %, preferably from
about 1 to 3 weight %. Especially preferred is about 0.5 to 1 weight % silane with
R = 4 or 8 carbon atoms, R' = alkoxy, and x = 1; and 1 weight % PDMS. The ratio of
silane to polysiloxane can be 1 silane:2 polysiloxane up to 2 silane:1 polysiloxane.

An especially preferred ratio is 1 silane: 1 polysiloxane.

The silane and polysiloxane are commercially available or can be
prepared by processes known in the art such as those described in "Organosilicon
Compounds", S. Pawlenko, et al., New York (1980), the teachings of which are
incorporated herein by reference. The method of addition is not especially critical
and the TiO₂ pigment may be treated with the silane in a number of ways. For
example, the silane addition can be made neat or prehydrolyzed to a dry pigmented base, from a slurry, a filtration step, during drying or at a size operation such as a fluid energy mill, e.g., micronizer, or media mill as described in greater detail in copending application entitled "IMPROVED SLURRY PROCESS FOR PREPARING SILANIZED TiO₂ PIGMENTS, USING A MEDIA MILL", the teachings of which are incorporated herein by reference, or post blending after micronizing. For example, U.S. 3,834,924 describes organosilane and pigment dispersion mixed or blended directly in a suitable solids mixing apparatus. An example of post blending is described in greater detail in U.S. Patents 3,915,735 and 4,141,751. The polysiloxane addition can be made in conjunction with the silane or post addition to the silanized pigment. The silane addition and polysiloxane addition is described in greater detail below. If water, either a liquid or vapor (steam), is present as a component of the process stream, hydrolysis of the hydrolyzable groups of the silane will occur and the silane coating will bond to the TiO₂ base. Prehydrolyzing the silane is a preferred step in treating the TiO₂ pigment with the silane. If the silane is added neat to the TiO₂ base, then moisture absorbed on the TiO₂ will effect the hydrolysis, but at a lower rate than if excess moisture is present. Hydrolysis of silanes is described in greater detail in "Organofunctional Silanes" by Union Carbide (1991), the teachings of which are incorporated herein by reference.

Polymers which are suitable for use in the present invention include, by way of example but not limited thereto, polymers of ethylenically unsaturated monomers including olefins such as polyethylene, polypropylene, polybutylene, and copolymers of ethylene with higher olefins such as alpha olefins containing 4 to 10 carbon atoms or vinyl acetate, etc.; vinyls such as polyvinyl chloride, polyvinyl esters such as polyvinyl acetate, polystyrene, acrylic homopolymers and copolymers; phenolics; alkyds; amino resins; epoxy resins, polyamides, polyurethanes; phenoxy resins, polysulfones; polycarbonates; polyether and chlorinated polyesters; polyethers; acetal resins; polyimides; and polyoxymethylene. The polymers according to the present invention also include various rubbers and/or elastomers either natural or synthetic polymers based on copolymerization, grafting, or physical blending of various diene monomers with the above-mentioned polymers, all as generally known in the art. Thus generally, the present invention is useful for any such white-pigmented plastic or elastomeric compositions (collectively referred to herein as a white-pigmented polymers). For example, but not by way of limitation,
the invention is felt to be particularly useful for polyolefins such as polyethylene, polypropylene, polyvinyl chloride, polyamides and polyesters.

As used herein, "high loaded" TiO₂ may vary widely for each polymeric matrix but will be in a well known range for those skilled in the art. For example, in a polyolefin matrix, a high loaded TiO₂ would be 50 or above % by weight TiO₂ pigment, based on the weight of the polyolefin matrix.

A wide variety of conventional additives may be included in the polymers as is necessary, desirable or conventional for the intended end use. Such additives include, but are not limited to, antioxidants, light stabilizers, lubricants, thermal processing additives and the like.

TiO₂ coated with organosilicon compounds can be incorporated into a melt-fabricable polymer to form the polymer composition of this invention by any melt compounding technique known in the art. Generally, TiO₂ and polymer resin are brought together and then mixed in a blending operation that applies shear to the polymer melt. The polymer resin is usually available in the form of powder, granules, pellets, or cubes. Commonly, TiO₂ and resin are first combined while the resin is in the solid state (not melted) and dry-blended in some way. This can be done in simple ways, such as by shaking in a bag or tumbling in a closed container, or in more sophisticated ways such as by using blenders having agitators or paddles.

TiO₂ and polymer resin can be brought together by co-feeding the materials to internal mixers and allowing a screw to mix them together before the resin reaches the molten state. The melt blending of TiO₂ and polymer resin can be done using known equipment, such as single-screw extruders, twin-screw extruders, internal mixers, and the like. Internal mixers are commonly used. The melt blending can be done as part of the process of forming a finished article of the composition, as by melt extrusion. Alternatively, the melt blending can be done in a preliminary step, optionally isolating the polymer composition, e.g., as cubes, followed by forming a finished article in a subsequent process. As one skilled in the art will recognize, there are many possible variations of the technique for preparing polymer compositions of the invention. One may, for example, first prepare a concentrate having high TiO₂ concentration, i.e., one composition of the invention, and then combine the concentrate with polymer resin containing no TiO₂ to obtain another composition of the invention.

The highly loaded polymer concentrates are made as described above with the desirable weight % for the intended end use. For example, in polyolefin
concentrates, about 50-87% by weight concentrate may be used to opacify. The concentrate is "let down" into the polyolefin. Used herein, "let down" refers to a ratio or percent of resin mixed with concentrate. Let down may be accomplished in a number of ways and is described in great detail in "Film Extrusion Manual" (1992), the teachings of which are incorporated herein by reference. For example, in lacing evaluation, a 50 wt.% to 87 wt.% concentrate may be let down to about 0.2 to about 20 weight % by dry mixing polyolefin and extruding at a specific processing temperature and casting it into a film. Pigment performance is then evaluated in an end use application.

The highly loaded silanized pigmented TiO₂ exhibits outstanding processibility in a polymeric matrix and lacing resistance when incorporated into a polyolefin matrix. Additional advantages observed are increased bulk density, lower viscosity, excellent dispersibility, moisture resistance, and excellent optical properties such as high tint strength.

The following examples are construed as illustrative and not limitative of the remainder of the disclosure in any way whatsoever. Farrel BR Banbury®-type mixers (available from Farrel Corp., Ansonia, CT, USA) have been used in the Examples. Broad range internal mixers as known in the art are contemplated equivalents. For example, Farrel Continuous Mixers (FCM) (available from Farrel Corp., Ansonia, CT, USA) and twin screw extruders are equally applicable.

Bulk density is given as grams per cubic centimeter of uncompacted pigment. A pigment bulk density below about 0.6 will result in difficult solids handling in polymer compounding. For rapid compounding of TiO₂ and a polymer in a Banbury®-type mixer, a bulk density above about 0.6 is desirable.

Total flux time is a measure of processing time, or time to disperse, in a Banbury®-type mixer.

Viscosity, at 180 degrees Celsius, of product from the Banbury®-type mixer, was measured at a shear rate of 550 1/sec. Viscosity was measured with a Kayeness capillary rheometer (available from Kayeness Corp., Honey Brook, PA, USA).
EXAMPLES

PREPARATION OF A CONCENTRATE, i.e., MASTERBATCH

In the following examples, a 70 wt.% compound of a dry mix TiO₂ balance polyethylene was prepared in the following manner. First, a dry mix of TiO₂/balance polyethylene was prepared via blending of 1562 grams of the TiO₂ with 670 grams of polyethylene. The polyethylene used for the experiments was a low density polyethylene supplied by Quantum U.S.I. Chemicals--Code = NA212 (Cincinnati, OH, USA).

The dry mix of TiO₂/polyethylene was added to the feed hopper of a laboratory Farrel BR Banbury®-type Mixer (chamber capacity = about 1100-about 1200 cc). The dry mix was then discharged into the Mixer. Stock pressure equaled 56 psi, driven rotor speed = 230 rpm, cooling water = 85°F. The Mixer was equipped with recording equipment for batch temperature, power consumption, ram pressure, and heat loss.

The mixture of TiO₂/polyethylene was subsequently processed until the TiO₂ dispersed into the melted resin (temperature = for example 220°F) defined above as total flux time. The compound was then discharged from the mixer.

EXAMPLE 1

3000 grams of neutralized pigmentary rutile TiO₂ were weighed into a pan and sprayed with 30 grams of butyl trimethoxy silane, as supplied by Union Carbide now Osi Specialty, Inc. (Tarrytown, NY, USA).

The treated pigment was ground in a fluid energy mill, e.g., micronizer with superheated steam.

The micronized pigment was mixed in a Patterson-Kelley V-Blender with 30 grams of polydimethylsiloxane, as supplied by Petrach now Huls Corp. (Piscataway, NJ, USA).

The treated TiO₂ polyethylene concentrate was prepared as described above.

EXAMPLE 2

Same as Example 1 except that octyl triethoxy silane was used in place of butyl trimethoxy silane.
EXAMPLE 3
Neutralized pigmented rutile TiO₂ was treated with about 1 wt% of each of octyl triethoxy silane and polydimethylsiloxane as for Example 1, except that these compounds were added at the micronizer, through existing nozzles in a grinding chamber. The treated pigment and low density polyethylene were then mixed and processed in a Banbury®-type mixer to form a 70 wt% masterbatch, as described above.

EXAMPLE 4
Neutralized pigmented rutile TiO₂ was treated with about 1 wt% of octyl triethoxy silane, by spraying, as for Example 1. There was no treatment with polydimethylsiloxane. The treated pigment was micronized, and used for processing in a Banbury®-type mixer to a 70 wt% polyethylene masterbatch, as described above.

COMPARATIVE EXAMPLE 5 (C-5)
Pigmentary rutile TiO₂ and low density polyethylene were mixed and processed in a Banbury®-type mixer to form a 70 wt% polyethylene masterbatch, as described above.

The results of the tests on the masterbatches from Examples 1-5 are summarized in the table below.

This data demonstrated the processing advantages of organosilicon compound treated pigments (Examples 1-4) versus a non-treated pigment (Example C-5) in a 70 wt.% TiO₂/polyethylene masterbatch. Shown in the table
are bulk density improvements realized by the organosilicon compound treatments, total flux time improvements, and viscosity improvements for these materials over non-treated.

EXAMPLE 6

Dried, crushed, meshed pigmentary rutile TiO₂ filter cake was sprayed with about 1 wt. % of neat octyl triethoxy silane, as supplied by Osi.

The treated pigment was micronized and used for processing in a Banbury®-type mixer to a 70 wt. % polyethylene masterbatch, as described above.

COMPARATIVE EXAMPLE 6A

Same as Example 6 except butyl trimethoxy silane was used in place of octyltriethoxysilane. The results of the tests on the masterbatches from Examples 6-6A are summarized in the table below.

<table>
<thead>
<tr>

This data demonstrated the differences for a higher chain alkyl silane (Example 6) versus a lower chain alkyl silane. Surprisingly, the lower chain alkyl silanes resulted in longer processing times. The lower chain alkyl silane realized a 70% increase in processing time over the higher chain alkyl silane.

EXAMPLE 7

3000 grams of pigmentary rutile TiO₂ was treated with 1 weight % (30 grams) octyltriethoxysilane via spraying. Material was processed in a Banbury®-type mixer at 70 weight % in a polyethylene masterbatch as described above.

COMPARATIVE EXAMPLE 7A

3000 grams of pigmentary rutile TiO₂ was treated with 1 weight % (30 grams) polydimethylsiloxane (PDMS) via spraying. Material was processed in a
Banbury®-type mixer at 70 weight % in a polyethylene masterbatch as described above.

**EXAMPLE 8**

Pigmentary rutile TiO₂ was treated with 1 weight % octadecyltriethoxy silane (available from Huls) via spraying. Material was processed in a Banbury®-type mixer at 70 weight % in a polyethylene masterbatch as described above.

The results of tests on the masterbatches from Examples 7, 7A and 8 are summarized in the table below.

This data demonstrated a series of post-blended higher chain alkyl silane (Examples 7 and 8) and siloxane (Comparative Example 7A) treated materials. For the two silane treated materials (Examples 7 and 8) treated with a higher chain alkyl silane, final product viscosities were nearly identical. For the siloxane only (Comparative Example 7A) treated material viscosity and processing time were higher.

**EXAMPLE 9**

Silanized pigment, octyltriethoxysilane, and polyester were dry blended in a double cone blender for 5 minutes to yield a 50/50 mixture. This mixture was added to a feed hopper of a Farrel Continuous Mixer (FCM). The mixture of treated TiO₂/polyester was subsequently processed until the treated TiO₂ dispersed into the melted resin (temperature = 550°F). Observable flow of the concentrate was smooth and continuous.
COMPARATIVE EXAMPLE 9A
An untreated anatase pigment, Kronos 1072 (available from Kronos, Leverkuesen, Germany), was dry blended, fed and processed in the FCM as in Example 9. Observable flow of the concentrate was not smooth. Continuous flow was not attained.

LACING
Lacing occurs as a function of pigment volatility at specific wt % pigment loadings and processing temperature. For polyethylene films pigmented with titanium dioxide, 20 wt % TiO₂ in the film processed at temperatures of 620°F or greater will discern readily lacibility of the film. Typically, materials are rated 10 if they do not lace, and below 10 if they begin to lace.

Two materials are compared in the following for lacing.

EXAMPLE 10
By weight, 20% of an octyltriethoxy silane treated TiO₂ was compounded into balance polyethylene. Material was extruded on a Killion single screw extruder through a film die at 620°F. Evaluation of the film on a light box revealed superior integrity with no thin spots or pin-holes. Rating of material equaled 10. Lacing resistance was comparable to the industry standard, Ti-Pure® R-101, available from E. I. du Pont de Nemours and Company, Wilmington, DE, USA.

COMPARATIVE EXAMPLE 10A
By weight, 20% of a siloxane treated pigment RCL-69, (available from SCM, Baltimore, MD, USA) was compounded into balance polyethylene. Material was extruded on a Killion single screw extruder through a film die at 620°F. Material exhibited thin spots under a light box. Material was rated as a 7.

Having thus described and exemplified the invention with a certain degree of particularity, it should be appreciated that the following claims are not to be so limited but are to be afforded a scope commensurate with the wording of each element of the claim and equivalents thereof.
What is Claimed is:

1. A polymer matrix comprising polymer and about 0.01 to about 87% by weight silanized TiO₂ pigment, based on the weight of the polymer matrix, exhibiting enhanced processibility, wherein the silanized TiO₂ pigment has a coating of about 0.1 to about 5% by weight, based on the weight of the silanized TiO₂, of at least one organosilicon compound having the formula:

\[ R_xSi(R')_{4-x} \]

wherein
- R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group having 8-20 carbon atoms;
- R' is a hydrolyzable group selected from alkoxy, halogen, acetoxy or hydroxy or mixtures thereof; and
- \( x = 1 \) to 3.

2. A polymer matrix comprising polymer and about 0.01 to about 87% by weight silanized TiO₂ pigment, based on the weight of the polymer matrix, wherein the silanized TiO₂ pigment has a coating of about 0.1 to about 5% by weight based on the weight of the silanized TiO₂, of an organosilicon compound comprising a mixture of (a) and (b) wherein

(a) is at least one silane having the formula:

\[ R_xSi(R')_{4-x} \]

wherein
- R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group having 1-20 carbon atoms;
- R' is a hydrolyzable group selected from alkoxy, halogen, acetoxy or hydroxy or mixtures thereof; and
- \( x = 1 \) to 3; and

(b) is at least one polysiloxane having the formula:

\[ (R_nSiO_{4-n})_m \]

wherein
- R is an organic or inorganic group;
- \( n = 0 \) to 3; and...
m \geq 2.

3. The composition of Claim 1 or Claim 2 wherein the polymer is polyolefin.

4. The composition of Claim 3 wherein the polyolefin is polyethylene and the amount of silanized TiO\textsubscript{2} pigment present is about 50 to about 87\% by weight based on the weight of the polyethylene matrix.

5. The composition of Claim 1 or Claim 2 wherein the polymer is polyvinyl chloride.

6. The composition of Claim 1, Claim 2 or Claim 4 wherein R is aliphatic having 8-18 carbons, R’ is alkoxy, and x = 1 to 3.

7. The composition of Claim 2 wherein the mixture comprises the silane selected from the group consisting of butyltrimethoxysilane and octyltriethoxysilane, and the siloxane is polydimethylsiloxane.

8. A polyolefin matrix comprising polyolefin and about 50 to about 87\% by weight of silanized TiO\textsubscript{2} pigment, based on the weight of the polymer matrix, exhibiting enhanced processibility, wherein the silanized TiO\textsubscript{2} pigment has a coating of about 0.1 to about 5\% by weight, based on the weight of the silanized pigment, of an organosilicon compound having the formula:

\[ R_x Si(R')_{4-x} \]

wherein
R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group having 8-20 carbon atoms;
R’ is a hydrolyzable group selected from alkoxy, halogen, acetoxy or hydroxy mixtures thereof; and
x = 1 to 3.

9. The composition of Claim 8 wherein the polyolefin is polyethylene.
10. The composition of Claim 1, Claim 2, Claim 8 or Claim 9 wherein the silanized pigment is present in the amount of about 70 to about 82 % by weight and the organosilicon compound is selected from the group consisting of octyltriethoxysilane, nonyltriethoxysilane, decyltriethoxysilane, dodecyltriethoxysilane, tridecyltriethoxysilane, tetradecyltriethoxysilane, pentadecyltriethoxysilane, hexadecyltriethoxysilane, heptadecyltriethoxysilane, octadecyltriethoxysilane, mixtures thereof; and mixtures of butyltrimethoxysilane and polydimethylsiloxane, and mixtures of octyltriethoxysilane and polydimethylsiloxane.

11. The polyolefin matrix of Claim 10 wherein
(a) the polyolefin is polyethylene;
(b) the silanized TiO₂ is TiO₂ coated with about 0.5 to 1.5 % by weight of an octyltriethoxysilane; and
(c) the silanized TiO₂ pigment is present in the amount of about 70 % by weight.

12. The polyethylene matrix of Claim 11 wherein the coating comprises about 1% by weight of butyltrimethoxysilane and 1% by weight polydimethylsiloxane.

13. The polyethylene matrix of Claim 11 wherein the coating further comprises 1% by weight polydimethylsiloxane.

14. The composition of Claim 8 wherein the polyolefin matrix exhibits resistance to lacing at TiO₂ concentration ranging from about 0.2 to about 20% by weight based on the weight of the polyolefin matrix.

15. A process for enhancing processibility in compounding highly loaded TiO₂ in a polymer matrix comprising the steps of:
(a) coating TiO₂ with an organosilicon compound so that a chemical bond is formed; and
(b) rapidly processing a high concentration of organosilicon coated TiO₂ with a polymer in an internal mixer at increased flux time.
16. The process of Claim 15 wherein the organosilicon compound has
the formula:
\[ R_x Si(R')_{4-x} \]

wherein
R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group
having 8-20 carbon atoms;
R' is a hydrolyzable group selected from alkoxy, halogen, acetoxy or
hydroxy or mixtures thereof; and
x = 1 to 3.

17. The process of Claim 15 wherein an organosilicon compound
comprises a mixture of (a) and (b) wherein
(a) is at least one silane having the formula:
\[ R_x Si(R')_{4-x} \]

wherein
R is a nonhydrolyzable aliphatic, cycloaliphatic or aromatic group
having 1-20 carbon atoms;
R' is a hydrolyzable group selected from alkoxy, halogen, acetoxy or
hydroxy or mixtures thereof; and
x = 1 to 3; and
(b) is at least one polysiloxane having the formula:
\[ \frac{(R_nSiO_{4-n})_m}{2} \]

wherein
R is an organic or inorganic group;
n = 0-3; and
m \geq 2.

18. The process of Claim 15, Claim 16 or Claim 17 wherein
(a) the polymer is polyolefin;
(b) the organosilicon compound is present in the amount of about
0.5 to about 5% by weight; and
(c) the high concentration of the TiO\textsubscript{2} ranges from about 50 to
about 82%.
**INTERNATIONAL SEARCH REPORT**

**A. CLASSIFICATION OF SUBJECT MATTER**

| IPC 6 | C09C1/36 | C08K9/06 |

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

| IPC 6 | C09C | C08K |

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consisted during the international search (name of data base and, where practical, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**
