(54) Title: ENHANCED ESCR BIMODAL ROTOMOLDING RESIN

Figure 3

(57) Abstract: The present invention provides a resin suitable for use in rotational molding having an environmental stress crack resistance of greater than 1000 hours. The resin has a density from 0.937 to 0.942 g/cm³, a melt index 12 determined according to ASTM D 1238 (2.16 kg 190°C - 12) from 4.0 to 7.0 g/10min, an 12 determined according to ASTM D 1238 (21.6 kg 190°C - 12) from 160 to 200 g/10 min, an 12/1/2 from 30 to 40 and a terminal vinyl unsaturation greater than 0.06, per 1000 carbon atoms; and a primary structure parameter (PSP) of 2.7 to 3.5 comprising from 2 to 5 weight % of one or more C4-8 alpha olefin comonomers.

ENHANCED ESCR BIMODAL ROTOMOLDING RESIN

TECHNICAL FIELD

The present invention relates to polyethylene for use in rotomolding articles. The polymers have exceptional environmental stress crack resistance in view of its high flow properties and stiffness which are useful in a number of custom applications including larger parts.

BACKGROUND ART

There are a number of different considerations for manufacturing a resin suitable for use in rotomolding manufacture. The resin needs to be: capable of production at commercially acceptable rates of production; suitable for use in the rotomolding process (e.g. for example having a suitable sintering temperature and a suitable cooling rate to be removed from the mold) and finally must have suitable properties for the end use application. One important property sought is environmental stress crack resistance. The resin should not develop cracks due to exposure to chemicals, sunlight, etc. in applications such as tank sprayers for agricultural use, cisterns, and smaller rotomolded parts.

United States Patents 5,382,630, and 631 issued January 17, 1995 to Stehling, assigned to Exxon teach bimodal resins having superior physical properties. The patent requires that the blend have a two or more components each having a polydispersity (Mw/Mn) less than 3 and the blend having a polydispersity greater than 3 and no component in the blend having a relatively higher molecular weight and a lower comonomer content (i.e. the comonomer incorporation is reverse). The reference does not suggest improved ESCR.

United States Patent 6,969,741 issued Nov. 29, 2005 to Lustiger et al., assigned to ExxonMobil teaches a blend of polyethylenes suitable for rotomolding. The patent teaches the difference in the density of each component is not less than 0.030 g/cm³. The difference in the densities of the component polymers in the present composition is less than 0.030 g/cm³.

United States Patent 8,486,323 issued July 16, 2013 in the name of Davis, assigned to Dow Global technologies Inc., teaches polymer blends used in rotational molded articles and having a high impact resistance. The blends have a residual
unsaturation of less than 0.06 per 1000 carbon atoms. The blends of the present invention have a residual unsaturation of greater than 0.06 per 1000 carbon atoms.

United States Patent 8,492,498 issued July 23, 2013 from an application filed Feb. 21, 2011 in the name of Buck et al., assigned to Chevron Phillips discloses a high density polymer suitable for rotational molding that has a bent strip ESCR condition A greater than 1000 hours, as determined by ASTM D 1693 in 100% IGEPAL CO-630. The polymer also has a primary structure parameter (PSP2) of greater than 8.9. The compositions of the present invention have a primary structure parameter (PSP2) of from 4 to 7.

United States Patents 8,141,946 issued Feb. 14, 2012, and 8,475,899 issued July 2, 2013 both claiming a priority date of Dec. 18, 2008 in the name of Yang et al., assigned to Chevron Phillips teach a polymer prepared using a bridged metallocene catalyst and having a long chain branches (LCB) content of less than 0.008 per 1000 carbon atoms, by implication LCB are present in the polymer. The catalyst and process used to make the polymers of the present invention do not produce detectable long chain branching.

The present invention seeks to provide a high density polyethylene resin having exceptional environmental stress crack resistance (ESCR) and good flow properties. Flow properties are important for rotomolding resins as the resin must soften and flow in the mold. If the flow properties are too low the resin does not sinter together in a reasonable amount of time and the product cannot be made in an economical manner.

**DISCLOSURE OF INVENTION**

In one aspect the present invention provides a bimodal polyethylene composition having a density from 0.937 to 0.942 g/cm³, a melt index I₂ determined according to ASTM D 1238 (21.6 kg 190°C - I₂) from 4.0 to 7.0 g/10min, and I₂/i determined according to ASTM D 1238 (21.6 kg 190°C - I₂/i) from 160 to 200 g/10 min, an I₂/i/I₂ from 30 to 40, a bent strip ESCR as determined by ASTM D 1693 in 100% octoxynol -9 for conditions A and B of greater than 1000 hours and a terminal vinyl unsaturation greater than 0.06, preferably greater than 0.08 per 1000 carbon atoms; a primary structure parameter (PSP2) of from 4 to 7, preferably 5 to 6, and an overall Mw/Mn from 2.7 to 3.5 comprising from 2 to 6 weight % of one or more C₄₋₅ alpha olefin comonomers which when de-convoluted into two components consists of:

(i) from 20 to 45, preferably 20 to 35, most preferably from 25 to 35, weight % of a first component with a branch frequency per 1000 carbon atoms by FTIR
between 3 and 13, said component having a density as determined according to ASTM D 792 from 0.920 to 0.930 g/cm³; a weight average molecular weight (Mw) from 100,000 to 180,000 preferably from 110,000 to 165,000, most preferably from 120,000 to 150,000 g/mol and a polydispersity of less than 3; and

(ii) from 80 to 55, preferably from 80 to 65, most preferably from 75 to 65 weight % of a second component comprising from 0 up to 1, preferably from 0.2 to 0.6 wt % of one or more of one or more C₄₋₈ alpha olefin comonomers and the balance ethylene said component having a density as determined according to ASTM D 792 from 0.945 to 0.955 g/cm³; a weight average molecular weight (Mw) from 15,000 to 70,000, preferably from 20,000 to 40,000 and a polydispersity of less than 3 wherein in the difference in densities between components (i) and (ii) is less than 0.030, preferably less than 0.027 g/cm³, and the polymer has no detectable long chain branches.

In a further aspect the present invention provides a bimodal polyethylene composition as above having a primary structure parameter (PSP2) from 4 to 7.

In a further aspect the present invention provides a bimodal polyethylene composition as above wherein component (i) is present in an amount from 20 to 35 weight %.

In a further aspect the present invention provides a bimodal polyethylene composition as above, wherein component (i) consists of from 1 to 25 weight % of one or more of one or more C₄₋₈ alpha olefin comonomers and the balance ethylene.

In a further aspect the present invention provides a bimodal polyethylene composition as above wherein component (i) has a weight average molecular weight (Mw) from 120,000 to 150,000 g/mol and a polydispersity less than 3.

In a further aspect the present invention provides a bimodal polyethylene composition as above wherein component (ii) is present in an amount from 65 to 80 weight %.

In a further aspect the present invention provides a bimodal polyethylene composition as above having wherein component (ii) has a weight average molecular weight (Mw) from 20,000 to 50,000 and a polydispersity less than 3.

In a further aspect the present invention provides a bimodal polyethylene composition as above wherein the difference in densities between components (i) and (ii) is less than 0.030, preferably less than 0.027 g/cm³.

In a further embodiment the present invention provides a process to make a bimodal polyethylene composition as above, comprising feeding ethylene and one or
more C₄₋₈ comonomers to two sequential solution phase reactors, in the presence of a
single site catalyst comprising a phosphinimine ligand together with one or more
activators.

In a further embodiment the present invention provides a rotomolded part
consisting essentially of the above bimodal polyethylene composition.

**BRIEF DESCRIPTION OF DRAWINGS**

Figure 1 is a plot of the molecular weight distribution obtained by gel permeation
chromatograph (GPC), and the short chain branching distribution determined from
GPC-FTIR of a resin of example 1.

Figure 2 is a plot of a plot of the calculated \( w_s \cdot \text{PSP2} \), values against log M for
the resin of example 1.

Figure 3 is a plot of the molecular weight distribution obtained by GPC of the
polymer of example 1 and the computer model predictions of the molecular weight
distributions of the first and second ethylene polymers that are comprised in the
polymer of example 1.

Figure 4 is a plot of the molecular weight distribution obtained by gel permeation
chromatograph (GPC), and the short chain branching distribution determined from
GPC-FTIR of a resin of example 1. The plot also includes the computer model
predictions of the polymer molecular weight distribution as well as the short chain
branching distribution.

Figure 5 is a plot of the mean failure energy from ARM impact testing carried out
at -40°C on specimens taken from rotomolded parts of the resin of example 1.

Figure 6 is a plot of the bent strip ESCR condition A 100 against the flexural
secant modulus 1% in MPa for the resin of example 1.

**BEST MODE FOR CARRYING OUT THE INVENTION**

Numbers ranges

[1] Other than in the operating examples or where otherwise indicated, all
numbers or expressions referring to quantities of ingredients, reaction conditions, etc.
used in the specification and claims are to be understood as modified in all instances by
the term "about". Accordingly, unless indicated to the contrary, the numerical
parameters set forth in the following specification and attached claims are
approximations that can vary depending upon the properties that the present invention
desires to obtain. At the very least, and not as an attempt to limit the application of the
doctrine of equivalents to the scope of the claims, each numerical parameter should at
least be construed in light of the number of reported significant digits and by applying ordinary rounding techniques.

[2] Notwithstanding that the numerical ranges and parameters setting forth the broad scope of the invention are approximations, the numerical values set forth in the specific examples are reported as precisely as possible. Any numerical values, however, inherently contain certain errors necessarily resulting from the standard deviation found in their respective testing measurements.

[3] Also, it should be understood that any numerical range recited herein is intended to include all sub-ranges subsumed therein. For example, a range of "1 to 10" is intended to include all sub-ranges between and including the recited minimum value of 1 and the recited maximum value of 10; that is, having a minimum value equal to or greater than 1 and a maximum value of equal to or less than 10. Because the disclosed numerical ranges are continuous, they include every value between the minimum and maximum values. Unless expressly indicated otherwise, the various numerical ranges specified in this application are approximations.

[4] All compositional ranges expressed herein are limited in total to and do not exceed 100 percent (volume percent or weight percent) in practice. Where multiple components can be present in a composition, the sum of the maximum amounts of each component can exceed 100 percent, with the understanding that, and as those skilled in the art readily understand, that the amounts of the components actually used will conform to the maximum of 100 percent.

The polymers of the present invention are bimodal polyethylene and can be de-convolved into two distinct components. Typically, this is demonstrated by the presence of a "shoulder" at the right side of a gel permeation chromatography (GPC) curve (Figure 1). In the present case there is a small shoulder to the right side of the GPC curve as shown in Figure 2 indicating a small amount of a higher molecular weight low density component.

The overall polyethylene composition comprises from 0.1 to 8.0, typically from 2.0 to 6.0 weight % of one or more C₆-αs alpha olefins and the balance ethylene. Preferably the comonomer is 1-octene but it could also be 1-hexene.

In the present invention, the higher molecular weight component is present in an amount from 20 to 45 weight % of the entire composition, preferably from 20 to 35 weight %, most preferably from 25 to 30 weight %, based on the weight of the entire composition. The lower molecular weight component is present in corresponding
amounts from 80 to 55 weight %, of the entire composition, preferably from 80 to 65 weight %, most preferably from 65 to 75 weight % based on the weight of the entire composition.

The higher molecular weight component has a weight average molecular weight (Mw) greater than 100,000, typically from 110,000 to 165,000, preferably from 120,000 to 150,000, as determined using gel permeation chromatography (GPC). The higher molecular weight component has a polydispersity (Mw/Mn: weight average molecular weight / number average molecular weight) less than 3 (e.g. between 2 and 3) typically less than 2.7.

The higher molecular weight component has a lower density than the lower molecular weight component. The density of the higher molecular weight component in the polymer may range from 0.920 to 0.930 g/cm³, typically from 0.922 to 0.926 g/cm³, preferably from 0.922 to 0.925 g/cm³. The density of the component, or that of any other component or the total composition, is a function of the degree of comonomer incorporation. The higher molecular weight component has a degree of short chain branching per 1000 carbon atoms from 3 to 13, typically from 4 to 10, preferably from 4 to 8. The higher molecular weight component does not have any long chain branching.

The lower molecular weight component has a weight average molecular weight (Mw) less than 100,000, typically from 15,000 to 70,000, preferably from 20,000 to 50,000, desirably from 20,000 to 40,000 g/mol, as determined using gel permeation chromatography (GPC). The lower molecular weight component has a polydispersity (Mw/Mn) less than 3 (e.g. from 2 to 3) typically less than 2.8.

The lower molecular weight component has a higher density than the higher molecular weight component. The density of the lower molecular weight component in the polymer is greater than 0.945 g/cm³, typically from 0.945 to 0.955 g/cm³, preferably from 0.947 to 0.952 g/cm³. The lower molecular weight (higher density component) has a degree of short chain branching of less than 5 per 1000 carbon atoms, typically from 0.5 to 4, preferably from 1 to 3 short chain branches per 1000 carbon atoms. The lower molecular weight component does not have any long chain branching.

The difference in density of the higher molecular weight component and the lower molecular weight components is less than 0.030 g/cm³, preferably less than 0.027 g/cm³.

The catalysts used to produce the polymers of the present invention do not produce long chain branching.
The overall properties of the polyethylene composition include the following:
density from 0.935 to 0.942 g/cm³;
melt index under a load of 2.16 kg (L2) at a temperature of 190°C as determined
by ASTM 1238 from 4 to 7, preferably from 4.5 to 6 g/10 minutes;
a melt index under a load of 21.6 kg (L1) at a temperature of 190°C as
determined by ASTM 1238 from 150 to 210, preferably from 160 to 200 g/10 minutes;
a melt flow ratio (L2/L1) from 28 to 40, preferably from 30 to 37;
a primary structure parameter (PSP2) from 4 to 7, preferably from 5 to 6;
an ESCR at condition A 100% IGEPAL® CO-630 (octoxynol-9) greater than 1000
hours; and
an ESCR at condition B 100% IGEPAL® CO-630 greater than 1000 hours.
Overall the composition comprises from 2 to 8, preferably from 2 to 5 weight %
of one or more C₄-s.comonomers.
The overall polymer incorporates the following molecular features:
Short chain branch frequency /1000 carbon atoms by FTIR between 1 and 8,
preferably between 3 and 6;
Comonomer content (wt. %) by FTIR from 0.1 to 8.0, preferably from 2.0 to 5.0;
Internal unsaturation per 1000 carbon atoms by FTIR from 0.07 to 0.3;
Side chain unsaturation per 1000 carbon atoms by FTIR typically less than 0.1;
Terminal unsaturation per 1000 carbon atoms by FTIR from 0.07 to 0.14;
Number average molecular weight (Mn) by GPC from 11,000 to 35,000,
preferably from 20,000 to 25,000;
Weight average molecular weight (Mw) by GPC from 55,000 to 82,000, preferably
from 60,000 to 70,000;
Z average molecular weight (Mz) by GPC from 140,000 to 200,000, preferably
from 160,000 to 180,000;
Polydispersity (Mn/Mw) from 2.7 to 5, preferably from 2.8 to 4, desirably less
than 3.5;
An index (Mz/Mw) from 2.0 to 2.9, preferably from 2.30 to 2.60; and
A primary structure parameter (PSP2) of from about 4 to 7, preferably from
5 to 6.
The PSP2 calculation as outlined by DesLauriers and Rohlfing in
Macromolecular Symposia (2009), 282 (Polyolefin Characterization-ICPC 2008),
pages 136-1 49 is incorporated by reference herein. The PSP2 calculation can be
generally described as a multistep process. The first step involves estimating the homopolymer (or low comonomer polymer) density of a sample from the sample's molecular weight distribution as described by Equation 1. The first step takes into account the effects of molecular weight on sample density.

\[
1 / p = \sum (w_i / \rho_i) = J 1 / p (\text{dw}/d\text{Log } M) \ d\text{Log } M \quad \text{(Eq. 1)}
\]

where: \( p = 1.0748-\text{(0.0241 )Log } M \).

Density values at molecular weights less than 720 g/mol are equal to 1.006 g/cm\(^3\) according to this method. In the second step, to further account for the added contributions to density suppression by the presence of short chain branching for each molecular weight (MW) slice, the difference between the measured bulk density of copolymer and the calculated homopolymer density is divided by the overall short chain branching (SCB) level (as measured by size exclusion chromatography-Fourier transform infrared spectroscopy or by C\(_{13}\)-NMR) and subsequently applied to the SCB level in each MW slice. The original observed bulk density of the copolymer (down to 0.852 g/cm\(^3\)) is obtained through summation of the MW slices as described above. The calculations have been simplified by assuming that all SCB levels will have the same effect on density suppression. However, it is to be understood that the effectiveness of a particular SCB level to suppress density will vary (i.e., the ability of SCB to disrupt crystallinity decreases as the level of SCB increases). Alternately, if the density of the copolymer is not known, then the effects of SCB on sample density can be estimated in the second step by using Equation 2 as described by DesLauriers and Rohlfing in Patent Application Publication No. 2007/0298508, where the change in density \( \Delta \rho \) refers to the value that is subtracted from the value given in equation 1 on a molecular slice by slice basis.

\[
\Delta \rho = C_1(\text{SCB/PDI}^n)^{-n} - C_2(\text{SCB/PDI}^n)^{-n} + C_3(\text{SCB/PDI}^n)^{-n} + C_4(\text{SCB/PDI}^n)^{-n} \quad \text{(Eq. 2)}
\]

In Equation 2, \( C_1=1.25E-02, \ C_2=0.5, \ C_3=7.51 \ E-05, \ C_4=0.62 \) and \( n=0.32 \).

The third step in calculating PSP2 is to calculate the quantity of \( 2 \ l_c + l_a \) where \( l_c \) is the estimated crystalline lamella thickness (in nm) and \( l_a \) is the estimated thickness (in nm) of the amorphous material at a particular molecular weight given by the following equations:
\[ T_m(°C) = (20587.5 149640828 )p^3 - (63826.2771547794 p^2 + (65965.7028912473 ) - 22585.2457979131 \]  

\[ l_c(nm) = \frac{0.624 nm \cdot T_m^0(K)}{T_m^0(K) - T_m(K)} \]  

In equation 3, assigned values of 20°C and 142.5°C are given for density values of 0.852 g/cm³ and 1.01 g/cm³, respectively. Equation 4 is a form of the well accepted Gibbs Thompson equation. The thickness of the amorphous layer \( l_a \) is calculated using the equations 5a and 5b:

\[ w_c = \frac{(\rho_c)(\rho - \rho_o)}{\rho_c - \rho_o} \]  

\[ l_o = \rho_c l_c(1 - w_c)/\rho_o w_c \]  

where: \( w_c \) = weight fraction crystallinity

\( p = \) calculated density of MW slice

\( \rho_c = \) density of 100% crystalline sample (assigned 1.006 g/cm³)

\( \rho_a = \) density of amorphous phase (0.852 g/cm³)

The fourth step calculates the tie molecule probability \( P \) for each molecular weight and respective

\[ 2l_c + l_a \] value according to equations 6a and 6b:

\[ P = \frac{1}{3} \int_{0}^{\infty} r^2 \exp(-b^2 r^2) dr \]  

\[ \frac{1}{3} \int_{0}^{\infty} r^2 \exp(-b^2 r^2) dr \]  

where \( b^2 = \frac{3}{2f^2} \) and \( f^2 = (Dn)^2 \).

The symbols above have the following meanings:

\( P = \) Probability of tie-chain formation
L = Critical distance (nm) = 2 |c_+l_a|

D = Chain extension factor in melt = 6.8 for polyethylene

n = Number of links = M_w/14 for polyethylene

l = The link length = 0.153 nm for polyethylene

\[ P = \frac{1}{3} \frac{\sqrt{\pi}}{4b^3} \int_0^L r^2 e^{-x_p(r^2-b^2)} \, dr \]  
\[ = \frac{1}{3} \left( \frac{4b^3}{\sqrt{\pi}} \int_0^L r^2 e^{-b^2r^2} \, dr \right) \]  
\[ = \frac{1}{3} \left( \frac{4b^3}{\sqrt{\pi}} \right) \left( \frac{L^2}{2} \right) \]  
\[ = \frac{1}{2} \frac{4b^3}{\sqrt{\pi}} L^2 \]  
\[ E_{eq, 6b} \]

Finally, PSP2 values are calculated from Equations 6a and 6b by treating this value essentially as a weighing factor (P) for each slice of the MWD, where P was arbitrarily multiplied by 100 and subsequently defined as PSP2. As in all of the aforementioned calculations, this value at each slice is multiplied by the respective weight fraction (w,) of the MWD profile in order to obtain a value for the bulk polymer.

A plot of the calculated w,·PSP2 values against log M for the inventive example 1 is shown in Figure 2, which can also be insightful when attempting to understand and predict structure property relationships. The area underneath the resulting w,·PSP2 vs. log M curve defines PSP2 for the whole polymer sample.

The polymer may be made using a solution polymerization technique. In the solution polymerization of ethylene with one or more comonomers, typically C_3-C_8 alpha olefins, preferably hexene or octene, most preferably octene, the monomers are typically dissolved in an inert hydrocarbon solvent, typically a C_5-C_12 hydrocarbon, which may be unsubstituted or substituted by a C_1-C_4 alkyl group, such as pentane, methyl pentane, hexane, heptane, octane, cyclohexane, methylcyclohexane and hydrogenated naphtha. An example of a suitable solvent that is commercially available is "Isopar E" (C_5-C_12 aliphatic solvent, Exxon Chemical Co.).

Catalyst and activators are also dissolved in the solvent or suspended in a diluent miscible with the solvent at reaction conditions.

The Catalyst

The catalyst is a compound of the formula:
wherein M is selected from the group consisting of Ti, Zr and Hf; P I is a phosphinimine ligand of the formula:

\[
\begin{array}{c}
\text{R}^2_1 \\
\text{R}^2_1 - \text{P} = \text{N} - \\
\text{R}^2_1
\end{array}
\]

wherein each R^2_1 is independently selected from the group consisting of a hydrogen atom; a halogen atom; hydrocarbyl radicals, typically C_i-10, which are unsubstituted by or further substituted by a halogen atom; C-i-s alkoxy radicals; C_i-10 aryl or aryloxy radicals; amido radicals; silyl radicals of the formula:

\[-\text{Si}(\text{R}^{22})_3\]

wherein each R^{22} is independently selected from the group consisting of hydrogen, a C_i-s alkyl or alkoxy radical and C_i-10 aryl or aryloxy radicals; and a germanyl radical of the formula:

\[-\text{Ge}(\text{R}^{22})_3\]

wherein R^{22} is as defined above;

L is a monoanionic cyclopentadienyl-type ligand independently selected from the group consisting of cyclopentadienyl-type ligands, Y is independently selected from the group consisting of activatable ligands; m is 1 or 2; n is 0 or 1; p is an integer and the sum of m+n+p equals the valence state of M.

The preferred phosphinimines are those in which each R^2_1 is a hydrocarbyl radical, preferably a C_i-6 hydrocarbyl radical, most preferably a C_i-4 hydrocarbyl radical.

The term "cyclopentadienyl" refers to a 5-member carbon ring having delocalized bonding within the ring and typically being bound to the active catalyst site, generally a group 4 metal (M) through η^5 - bonds. The cyclopentadienyl ligand may be unsubstituted or up to fully substituted with one or more substituents selected from the group consisting of C_i-10 hydrocarbyl radicals which are unsubstituted or further substituted by one or more substituents selected from the group consisting of a halogen atom and a C_i-4 alkyl radical; a halogen atom; a C-i-s alkoxy radical; a C_i-10 aryl or...
aryloxy radical; an amido radical which is unsubstituted or substituted by up to two C_i-8 alkyl radicals; a phosphido radical which is unsubstituted or substituted by up to two C_i-8 alkyl radicals; silyl radicals of the formula -Si-(R)_3 wherein each R is independently selected from the group consisting of hydrogen, a C_i-8 alkyl or alkoxy radical, C_i-8 aryl or aryloxy radicals; and germanyl radicals of the formula Ge-(R)3 wherein R is as defined above.

Preferably the cyclopentadienyl-type ligand is selected from the group consisting of a cyclopentadienyl radical, an indenyl radical and a fluorenyl radical which radicals are unsubstituted or up to fully substituted by one or more substituents selected from the group consisting of a fluorine atom, a chlorine atom; C_i-4 alkyl radicals; and a phenyl or benzyl radical which is unsubstituted or substituted by one or more fluorine atoms.

Activatable ligands Y may be selected from the group consisting of a halogen atom, C_i-4 alkyl radicals, C_6-20 aryl radicals, C_7-12 aryalkyl radicals, C_6-10 phenoxy radicals, amido radicals which may be substituted by up to two C_i-4 alkyl radicals and C_i-4 alkoxy radicals. Preferably, Y is selected from the group consisting of a chlorine atom, a methyl radical, an ethyl radical and a benzyl radical.

Suitable phosphinimine catalysts are Group 4 organometallic complexes which contain one phosphinimine ligand (as described above) and one cyclopentadienyl-type (L) ligand and two activatable ligands. The catalysts are not bridged.

**Activators**

The activators for the catalyst are typically selected from the group consisting of aluminoxanes and ionic activators.

**Aluminoxanes**

Suitable alumoxane may be of the formula: \( (R^4)_2\text{AlO}(R^4\text{AlO})_m\text{Al}(R^4)_2 \) wherein each R^4 is independently selected from the group consisting of C_1-20 hydrocarbyl radicals and m is from 0 to 50, preferably R^4 is a C_i-4 alkyl radical and m is from 5 to 30. Methylalumoxane (or "MAO") in which each R is methyl is the preferred alumoxane.

Aluminoxanes are well known as cocatalysts, particularly for metallocene-type catalysts. Aluminoxanes are also readily available articles of commerce.

The use of an alumoxane cocatalyst generally requires a molar ratio of aluminum to the transition metal in the catalyst from 20:1 to 1000:1. Preferred ratios are from 50:1 to 250:1.
Commercially available MAO typically contains free aluminum alkyl (e.g. trimethylaluminum or "TMA") which may reduce catalyst activity and/or broaden the molecular weight distribution of the polymer. If a narrow molecular weight distribution polymer is required, it is preferred to treat such commercially available MAO with an additive which is capable of reacting with the TMA. Alcohols are preferred (with hindered phenols being particularly preferred) for this purpose.

"Ionic Activators" Cocatalysts

So-called "ionic activators" are also well known for metallocene catalysts. See, for example, U.S. Patent No. 5,198,401 (Hlatky and Turner) and U.S. Patent No. 5,132,380 (Stevens and Neithamer).

Whilst not wishing to be bound by any theory, it is thought by those skilled in the art that "ionic activators" initially cause the abstraction of one or more of the activatable ligands in a manner which ionizes the catalyst into a cation, then provides a bulky, labile, non-coordinating anion which stabilizes the catalyst in a cationic form. The bulky, non-coordinating anion permits olefin polymerization to proceed at the cationic catalyst center (presumably because the non-coordinating anion is sufficiently labile to be displaced by monomer which coordinates to the catalyst. Preferred ionic activators are boron-containing ionic activators described in (i) (iii) below:

(i) compounds of the formula \([\text{R}^{5}]^{+}\text{B(\text{R}^{7})_{4}}^{-}\) wherein \(\text{B}\) is a boron atom, \(\text{R}^{6}\) is an aromatic hydrocarbyl (e.g. triphenyl methyl cation) and each \(\text{R}^{7}\) is independently selected from the group consisting of phenyl radicals which are unsubstituted or substituted with from 3 to 5 substituents selected from the group consisting of a fluorine atom, a \(\text{C}_{1-4}\) alkyl or alkoxy radical which is unsubstituted or substituted by a fluorine atom; and a silyl radical of the formula \(\sim\text{Si-(R}^{9})_{3}\) wherein each \(\text{R}^{9}\) is independently selected from the group consisting of a hydrogen atom and a \(\text{C}_{1-4}\) alkyl radical; and

(ii) compounds of the formula \([(\text{R}^{8})_{t}\text{ZH}]^{+}\text{B(\text{R}^{7})_{4}}^{-}\) wherein \(\text{B}\) is a boron atom, \(\text{H}\) is a hydrogen atom, \(\text{Z}\) is a nitrogen atom or phosphorus atom, \(t\) is 2 or 3 and \(\text{R}^{8}\) is selected from the group consisting of \(\text{C}_{1-4}\) alkyl radicals, a phenyl radical which is unsubstituted or substituted by up to three \(\text{C}_{1-4}\) alkyl radicals, or one \(\text{R}^{8}\) taken together with the nitrogen atom may form an anilinium radical and \(\text{R}^{7}\) is as defined above; and

(iii) compounds of the formula \(\text{B(\text{R}^{7})}_{3}\) wherein \(\text{R}^{7}\) is as defined above.

In the above compounds preferably \(\text{R}^{7}\) is a pentafluorophenyl radical, and \(\text{R}^{6}\) is a triphenylmethyl cation, \(\text{Z}\) is a nitrogen atom and \(\text{R}^{8}\) is a \(\text{C}_{1-4}\) alkyl radical or \(\text{R}^{8}\) taken
together with the nitrogen atom forms an anilinium radical which is substituted by two 
Cl\textsubscript{-4} alkyl radicals.

The "ionic activator" may abstract one or more activatable ligands so as to ionize the 
catalyst center into a cation but not to covalently bond with the catalyst and to 
provide sufficient distance between the catalyst and the ionizing activator to permit a 
polymerizable olefin to enter the resulting active site.

Examples of ionic activators include: triethylammonium tetra(phenyl)boron; 
tripropylammonium tetra(phenyl)boron; tri(n-butyl)ammonium tetra(phenyl)boron; 
trimethylammonium tetra(p-tolyl)boron; trimethylammonium tetra(o-tolyl)boron; 
tributylammonium tetra(pentafluorophenyl)boron; tripropylammonium tetra(o,p-
dimethylphenyl)boron; tributylammonium tetra(m,m-dimethylphenyl)boron; 
tributylammonium tetra(p-trifluoromethylphenyl)boron; tributylammonium 
tetra(pentafluorophenyl)boron; tri(n-butyl)ammonium tetra(o-tolyl)boron; N,N-
dimethylanilinium tetra(phenyl)boron; N,N-diethylanilinium tetra(phenyl)boron; N,N-
diethylaniinium tetra(phenyl)n-butylboron, N,N-2,4,6-pentamethylanilinium 
tetra(phenyl)boron; di-(isopropyl)ammonium tetra(pentafluorophenyl)boron; 
dicyclohexylammonium tetra(phenyl)boron, triphenylphosphonium 
tetra(phenyl)boron; tri(dimethylphenyl)phosphonium 
tetra(phenyl)boron; tropilliun tetrakis(pentafluorophenyl) borate; triphenylmethylam 
tetrakispentafluorophenyl borate; benzene (diazonium) tetrakis(pentafluorophenyl 
borate; tropilliun phenyltrispentafluorophenyl borate; triphenylmethylam 
phenyltrispentafluorophenyl borate; benzene (diazonium) phenyltrispentafluorophenyl 
borate; tropilliun tetrakis(2,3,5,6-tetrafluorophenyl) borate; triphenylmethylam tetrakis 
(2,3,5,6-tetrafluorophenyl) borate; benzene (diazonium) tetrakis(3,4,5-trifluorophenyl) 
borate; tropilliun tetrakis(3,4,5-trifluorophenyl) borate; benzene (diazonium) tetrakis 
(3,4,5-trifluorophenyl) borate; tropilliun tetrakis(1,2,2-trifluoroethenyl) borate; 
triphenylmethylam tetrakis(1,2,2-trifluoroethenyl) borate; benzene (diazonium) tetrakis 
(1,2,2-trifluoroethenyl) borate; tropilliun tetrakis(2,3,4,5-tetrafluorophenyl) borate; 
triphenylmethylam tetrakis(2,3,4,5-tetrafluorophenyl) borate; and benzene (diazonium) 
tetrakis(2,3,4,5-tetrafluorophenyl) borate.

Readily commercially available ionic activators include: N,N-dimethylaniliniumtetras (pentafluorophenyl borate; triphenylmethylam 
tetrakis(pentafluorophenyl) borate; and trispentafluorophenyl borane.
The ionic activator may be used at about molar equivalents of boron to group IV metal in the catalyst. Suitable molar ratios of group IV metal from the catalyst to boron may range from 1:1 to 3:1, preferably from 1:1 to 1:2.

In some instances the ionic activator may be used in combination with an alkylating activator (which may also serve as a scavenger). The ionic activator may be selected from the group consisting of \((R^3)_pMgX_2r_p\) wherein \(X\) is a halide and each \(R^3\) is independently selected from the group consisting of \(C_1\) to \(O\) alkyl radicals and \(p\) is 1 or 2; \(R^3Li\) wherein in \(R^3\) is as defined above, \((R^3)_qZnX_2q\) wherein \(R^3\) is as defined above, \(X\) is halogen and \(q\) is 1 or 2; \((R^3)_sAlX_3s\) wherein \(R^3\) is as defined above, \(X\) is halogen and \(s\) is an integer from 1 to 3. Preferably in the above compounds \(R^3\) is a \(C_{i-4}\) alkyl radical, and \(X\) is chlorine. Commercially available compounds include triethyl aluminum (TEAL), diethyl aluminum chloride (DEAC), dibutyl magnesium \((Bu_2Mg)\), and butyl ethyl magnesium \((BuEtMg or BuMgEt)\).

If the phosphinimine catalyst is activated with a combination of ionic activators (e.g. boron compounds) and alkylating agent the molar ratio of group IV metal from the catalyst: metalloid (boron) from the ionic activator : metal from the alkylating agent may range from 1:1:1 to 1:3:1:0, preferably from 1:1:3:5 to 1:1:5:3.

Polymerization Process

The temperature of the reactor(s) in a high temperature solution process is from about 80°C to about 300°C, preferably from about 120°C to 250°C. The upper temperature limit will be influenced by considerations that are well known to those skilled in the art, such as a desire to maximize operating temperature (so as to reduce solution viscosity), while still maintaining good polymer properties (as increased polymerization temperatures generally reduce the molecular weight of the polymer). In general, the upper polymerization temperature will preferably be between 200 and 300°C. The most preferred reaction process is a "medium pressure process", meaning that the pressure in the reactor(s) is preferably less than about 6,000 psi (about 42,000 kiloPascals or kPa). Preferred pressures are from 10,000 to 40,000 kPa \((1450-5800 psi)\), most preferably from about 14,000-22,000 kPa \(2,000 psi to 3,000 psi)\).

In some reaction schemes the pressure in the reactor system should be high enough to maintain the polymerization solution as a single phase solution and to provide the necessary upstream pressure to feed the polymer solution from the reactor system through a heat exchanger system and to a devolatilization system. Other
systems permit the solvent to separate into a polymer rich and polymer lean stream to facilitate polymer separation.

The solution polymerization process may be conducted in a stirred "reactor system" comprising one or more stirred tank reactors or in one or more loop reactors or in a mixed loop and stirred tank reactor system. The reactors may be in tandem or parallel operation. In a dual tandem reactor system, the first polymerization reactor preferably operates at lower temperature. The residence time in each reactor will depend on the design and the capacity of the reactor. Generally the reactors should be operated under conditions to achieve a thorough mixing of the reactants. In addition, it is preferred that from 20 to 60 weight % of the final polymer is polymerized in the first reactor, with the balance being polymerized in the second reactor.

A particularly useful solution polymerization process uses at least two polymerization reactors in series. The polymerization temperature in the first reactor is from about 80°C to about 180°C (preferably from about 120°C to 160°C) and the second reactor is preferably operated at a higher temperature (up to about 220°C). The most preferred reaction process is a "medium pressure process", meaning that the pressure in each reactor is preferably less than about 6,000 psi (about 42,000 kilopascals or kPa), most preferably from about 2,000 psi to 3,000 psi (about 14,000 22,000 kPa).

**EXAMPLES**

**Test Methods**

Mn, Mw and Mz (g/mol) were determined by high temperature Gel Permeation Chromatography (GPC) with differential refractive index detection using universal calibration (e.g. ASTM-D646-99). The molecular weight distribution (MWD) is the ratio of the weight average molecular weight (Mw) over the number average molecular weight (Mn).

GPC-FTIR was used to determine the comonomer content as a function of molecular weight. After separation of the polymer by GPC an on-line FTIR measures the concentration of the polymer and methyl end groups. Methyl end groups are used in the branch frequency calculations. Conventional calibration allows for the calculation of a molecular weight distribution.

Mathematical de-convolutions were performed to determine the relative amount of polymer, molecular weight, and comonomer content of the component made in each reactor by assuming that each polymer component follows a Flory's molecular weight
distribution function and it has a homogeneous comonomer distribution across the whole molecular weight range. The uniform comonomer distribution of each resin component, which is the result from the use of a single site catalyst, allowed the estimation of the short chain branching content (SCB), in branches per 1000 carbon atoms for the first and second ethylene polymers, based on the de-convoluted relative amounts of first and second ethylene polymer components in the polyethylene composition, and their estimated resin molecular weight parameters from the above procedure.

The short chain branch frequency (SCB per 1000 carbon atoms) of copolymer samples was determined by Fourier Transform Infrared Spectroscopy (FTIR) as per ASTM D6645-01. A Thermo-Nicolet 750 Magna-IR Spectrophotometer was used for the measurement. FTIR was also used to determine internal, side chain and terminal levels of unsaturation.

Polyethylene composition density (g/cm$^3$) was measured according to ASTM D792.

Melt indexes $I_2$, $I_6$ and $I_1$ for the polyethylene composition were measured according to ASTM D1238.

The density and melt index of the first and second ethylene polymers that comprise the polyethylene composition were determined based on composition models. The following equations were used to calculate the density and melt index $I_2$ (REFERENCE US Patent No. 8,022,143 B2, by Wang, assigned to NOVA Chemicals and published Sep. 20, 201).

\[
\text{Density} = 0.979863 - 5.95808 \times 10^{-3} \left( \frac{M_n}{1000} \right)^{0.65} - 3.8133 \times 10^{-4} \left[ \log_{10}(M_n) \right]^3 - 5.77986 \times 10^{-6} \left( \frac{M_w}{M_n} \right)^3 + 5.57395 \times 10^{-3} \left( \frac{M_w}{M_w} \right)^{0.5}
\]

\[
\log_{10}(\text{Melt Index \text{I}_2}) = 22.326528 + 3.467 \times 10^{-3} \left[ \log_{10}(M_n) \right]^3 - 4.322582 \left[ \log_{10}(M_w) \right] - 1.80061 \times 10^{-1} \left[ \log_{10}(M_2) \right]^2 + 2.6478 \times 10^{-2} \left[ \log_{10}(M_2) \right]^3
\]
where Mn, Mw, Mz, and SCB/1000°C are the de-convoluted values of the individual ethylene polymer components, as obtained from the results of the de-convolution described above.

Primary melting peak (°C), heat of fusion (J/g) and crystallinity (%) were determined using differential scanning calorimetry (DSC) as follows: the instrument was first calibrated with indium; after which a polymer specimen is equilibrated at 0°C; the temperature was increased to 200°C at a heating rate of 10°C/min; the melt was then kept at that temperature for five minutes; the melt was then cooled to 0°C at a cooling rate of 10°C/min and kept at 0°C for five minutes; the specimen was heated a second time to 200°C at a heating rate of 10°C/min. The melting peak (Tm), heat of fusion and crystallinity reported are calculated based on the second heating cycle.

Plaques molded from the polyethylene compositions were tested according to the following ASTM methods: Bent Strip Environmental Stress Crack Resistance (ESCR), ASTM D1693; Flexural properties, ASTM D790; Tensile properties, ASTM D638.

Rotomolded parts were prepared in a rotational molding machine sold under the tradename Rotospeed RS3-160 by Ferry Industries Inc. The machine has two arms which rotate about a central axis within an enclosed oven. The arms are fitted with plates which rotate on an axis that is roughly perpendicular to the axis of rotation of the arm. Each arm is fitted with six cast aluminum molds that produce plastic cubes having dimensions of 12.5 inches (31.8 cm) x 12.5 inches x 12.5 inches. The arm rotation was set to about 8 revolutions per minute (rpm) and the plate rotation was set to about 2 rpm. These molds produce parts having a nominal thickness of about 0.25 inches (0.64 cm) when initially filled with a standard charge of about 3.7 kg of polyethylene resin in powder form (35 US mesh size). The temperature within the enclosed oven was maintained at a temperature of 560°C. The molds and their content were heated for specified period of time, until full powder densification is achieved. The molds were subsequently cooled in a controlled environment prior to removing the parts. Specimens were collected from the molded parts for density and color measurements.

The ARM impact test was performed in accordance with ASTM D5628 at a test temperature of -40°C.

**The Resin**

Bimodal polyethylene compositions were prepared at a dual reactor pilot plant. In this dual reactor process the content of the first reactor flows into the second reactor,
both of which are well mixed. The process operates using continuous feed streams. The catalyst (cyclopentadienyl Ti tri tert.butly phosphimine di chloride) with activator was fed to both reactors. The overall production rate was about 90 kg/hr.

The polymerization conditions are provided in Table 1.

The polymer compositions prepared at the pilot plant were stabilized using a conventional additive package for rotational molding applications prior to carrying out plaque testing trials.

The properties of the resulting resins are compared to an internal NOVA Chemicals base line resin and two commercially available rotomolding resins which are referred to as comparative example 2 and 3, respectively. Results are set forth in Table 2. The properties of pressed plaques as well as rotomolded parts made from the polyethylene compositions are presented in Tables 3 and 4.

</table>
The data shows the inventive example has a good rotational molding process window (Figure 3) together with excellent ESCR and stiffness performance (Table 3, Figure 4). Compared to examples with similar densities, the invention combines both high comonomer content and reverse comonomer distribution. The molecular attributes of the invention are critical in maintaining a combination of good rotomolding processability, high ESCR and a high density that in turns favors higher stiffness.

**INDUSTRIAL APPLICABILITY**

The resins of the present invention have good flow properties and high environmental stress crack resistance and are useful in rotomolding plastic parts.

CLAIMS

1. A bimodal polyethylene composition having a density from 0.935 to 0.942 g/cm³, a melt index \( I_2 \) determined according to ASTM D 1238 (2.16 kg, 190°C - \( I_2 \)) from 4.0 to 7.0 g/1 Omin, and \( I_{2,1} \) determined according to ASTM D 1238 (21.6 kg, 190°C - \( I_{2,1} \)) from 150 to 210 g/1 0 min, an \( I_{2,1}/I_2 \) from 28 to 40, a bent strip ESCR as determined by ASTM D 1693 in 100% octoxynol -9 for conditions A and B of greater than 1000 hours, a terminal vinyl unsaturation from 0.07 to 0.14 per 1000 carbon atoms, an overall \( M_w/M_n \) from 2.8 to 4.0, comprising from 0.1 to 8 weight % of one or more \( C_{4-8} \) alpha olefin comonomers which when de-convoluted into two components consists of:

   (i) from 20 to 45 weight % of a first component comprising one or more of \( C_{4-8} \) alpha olefin comonomers and the balance ethylene, said component having a density as determined according to ASTM D 792 from 0.920 to 0.930 g/cm³; a weight average molecular weight (\( M_w \)) from 100,000 to 180,000 g/mol and a polydispersity of less than 3; and

   (ii) from 80 to 55 weight % of a second component comprising one or more of \( C_{4-8} \) alpha olefin comonomers and the balance ethylene said component having a density as determined according to ASTM D 792 from 0.945 to 0.955 g/cm³, a weight average molecular weight (\( M_w \)) from 15,000 to 70,000, and a polydispersity of less than 3, wherein in the difference in densities between components (i) and (ii) is less than 0.030 g/cm³.

2. The bimodal polyethylene composition according to claim 1, having a primary structure parameter (PSP2) from 4 to 7.

3. The bimodal polyethylene composition according to claim 2, wherein component (i) is present in an amount from 20 to 35 weight %.

4. The bimodal polyethylene composition according to claim 3, wherein component (i) consists of from 1 to 25 weight % of one or more of one or more \( C_{4-8} \) alpha olefin comonomers and the balance ethylene.

5. The bimodal polyethylene composition according to claim 4, wherein component (i) has a weight average molecular weight (\( M_w \)) from 120,000 to 150,000 g/mol and a polydispersity of less than 3.

6. The bimodal polyethylene composition according to claim 5, wherein component (ii) is present in an amount from 80 to 65 weight %.
7. The bimodal polyethylene composition according to claim 6, wherein component (ii) has a weight average molecular weight (Mw) from 20,000 to 50,000 and a polydispersity of less than 3.

8. The bimodal polyethylene composition according to claim 7, wherein the difference in densities between components (i) and (ii) is less than 0.030 g/cc.

9. A process to make a bimodal polyethylene composition according to claim 1, comprising feeding ethylene and one or more $C_{4-8}$ comonomers to two solution phase reactors in the presence of a single site catalyst comprising a phosphinimine ligand together with one or more activators.

10. A rotomolded part consisting essentially of a bimodal polyethylene composition according to claim 1.

[ ] Further documents are listed in the continuation of Box C.  
[ ] See patent family annex.

* Special categories of cited documents:
  
  *A* document defining the general state of the art which is not considered to be of particular relevance
  
  *E* earlier application or patent but published on or after the international filing date
  
  *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
  
  *O* document referring to an oral disclosure, use, exhibition or other means
  
  *P* document published prior to the international filing date but later than the priority date claimed

  *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

  *X* document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

  *Y* document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

  *Z* document member of the same patent family

Date of the actual completion of the international search: 28 January 2015

Date of mailing of the international search report: 09/02/2015

Name and mailing address of the ISA:
European Patent Office, P.B. 5818 Patentlaan 2 NL - 2280 HV Rijswijk
Tel. (+31-70) 340-2040, Fax: (+31-70) 340-3016

Authorized officer: Lippert, Sigr rid
