(54) Title: METHOD AND APPARATUS FOR PREAMBLE TRAINING IN A MULTIPLE ANTENNA COMMUNICATION SYSTEM

WO 2006/001898 A1

(57) Abstract: Methods and apparatus are provided for communicating data in a multiple antenna communication system having N transmit antennas. According to one aspect of the invention, a header format includes a legacy preamble having at least one legacy long training field and an extended portion having at least N additional long training fields on each of the N transmit antennas. The N additional long training fields may be tone interleaved across the N transmit antennas and are used for MIMO channel estimation. The extended portion may include a short training field for power estimation. The short training field may be tone interleaved across the N transmit antennas and have an extended duration to support beam steering.

**METHOD AND APPARATUS FOR PREAMBLE TRAINING IN A
MULTIPLE ANTENNA COMMUNICATION SYSTEM**

Cross-Reference to Related Applications

5 The present application claims priority to United States Provisional Patent Application Serial Number 60/578,776, filed June 10, 2004, incorporated by reference herein.

Field of the Invention

10 The present invention relates generally to multiple antenna wireless communication systems, and more particularly, to preamble training techniques for a multiple antenna communication system.

Background of the Invention

15 Multiple transmit and receive antennas have been proposed to provide both increased robustness and capacity in next generation Wireless Local Area Network (WLAN) systems. The increased robustness can be achieved through techniques that exploit the spatial diversity and additional gain introduced in a system with multiple antennas. The increased capacity can be achieved in multipath fading environments with bandwidth efficient Multiple Input Multiple Output (MIMO) 20 techniques. A multiple antenna communication system increases the data rate in a given channel bandwidth by transmitting separate data streams on multiple transmit antennas. Each receiver receives a combination of these data streams on multiple receive antennas.

25 In order to properly receive the different data streams, receivers in a multiple antenna communication system must acquire the channel matrix through training. This is generally achieved by using a specific training symbol, or preamble, to perform synchronization and channel estimation. It is desirable for multiple antenna communication system to co-exist with legacy single antenna 30 communications systems (typically referred to as Single Input Single Output (SISO) systems). Thus, a legacy (single antenna) communications system must be able to interpret the preambles that are transmitted by multiple antenna communication

systems. Most legacy Wireless Local Area Network (WLAN) systems based upon OFDM modulation comply with either the IEEE 802.11a or IEEE 802.11g standards (hereinafter “IEEE 802.11a/g”). Generally, the preamble signal seen by the legacy device should allow for accurate synchronization and channel estimation for the part 5 of the packet that the legacy device needs to understand. Previous MIMO preamble formats have reused the legacy training preamble to reduce the overhead and improve efficiency. Generally, the proposed MIMO preamble formats include the legacy legacy training preamble and additional long training symbols, such that the extended MIMO preamble format includes at least one long training symbol for each transmit 10 antenna or spatial stream.

A number of frame formats have been proposed for evolving multiple antenna communication systems, such as MIMO-OFDM systems. Existing frame formats provide inaccurate estimations for the MIMO systems, such as inaccurate power measurement or outdated frequency offset and timing offset information, or fail 15 to provide full backwards compatibility to the legacy devices of some vendors. In one proposed MIMO frame format, each transmit antenna sequentially transmits one or more long training symbols, such that only one transmit antenna is active at a time. As the transmit antennas are switched on and off, however, the temperature of the corresponding power amplifier will increase and decrease, respectively. Generally, 20 such heating and cooling of the power amplifier will lead to “breathing” effects that cause the transmitted signal to have a phase or magnitude offset, relative to the desired signal.

It is therefore desirable to have a continuous transmission from all 25 transmit antennas to avoid temperature related signal “breathing.” Thus, in further proposed MIMO frame formats, orthogonality is maintained using cyclic delay diversity (CDD) or tone-interleaving across different transmit antennas. The CDD short training symbol, however, cannot measure the received signal power with sufficient accuracy. Thus, additional backoff is required in the RF chain and 30 additional dynamic range is required in the digitization process. Likewise, the tone interleaved design is not fully backwards compatible with a number of existing

802.11a/g devices that use short training for timing synchronization or use time domain channel estimation.

A need therefore exists for a method and system for performing channel estimation and training in a MIMO-OFDM system that is compatible with 5 current IEEE 802.11a/g standard (SISO) systems, allowing MIMO-OFDM based WLAN systems to efficiently co-exist with SISO systems. A further need exists for MIMO preamble formats and training techniques that provide improved automatic gain control.

10 **Summary of the Invention**

Generally, methods and apparatus are provided for communicating data in a multiple antenna communication system having N transmit antennas. According to one aspect of the invention, a disclosed header format includes a legacy preamble having at least one legacy long training field and an extended portion 15 having at least N additional long training fields on each of the N transmit antennas. The N additional long training fields may be tone interleaved across the N transmit antennas and are used for MIMO channel estimation. The extended portion may include a short training field for power estimation. The short training field may be tone interleaved across the N transmit antennas and have an extended duration to 20 support beam steering.

A more complete understanding of the present invention, as well as further features and advantages of the present invention, will be obtained by reference to the following detailed description and drawings.

FIG. 10 illustrates an exemplary architecture for generating the short training symbol of FIG. 8 at the transmitter of FIG. 1;

FIG. 11 illustrates an exemplary design for the first long training symbol of FIG. 8 in the exemplary two transmit branch implementation (or two 15 spatial streams case);

FIG. 12 illustrates an exemplary design for the second long training symbol of FIG. 8 in the exemplary two transmit branch implementation (or two spatial streams case);

FIGS. 13 and 14 illustrate preamble designs incorporating features of 20 the present invention that for exemplary three and four transmit antenna implementations, respectively;

FIG. 15 illustrates an alternate backwards compatible preamble design;

FIG. 16 illustrates an alternate preamble design incorporating features 25 of the present invention that reduces the length of the preamble;

FIG. 17 is a schematic block diagram of a transmitter that extends the preamble formats of the present invention for SVD-MIMO;

FIG. 18 illustrates a preamble format for SVD-MIMO; and

FIG. 19 illustrates a hybrid preamble design.

Detailed Description

The present invention provides preamble formats and techniques for preamble training for MIMO system. The training phase of a MIMO transmission will contain two phases. The first training phase is a legacy training phase 5 particularly suited, for example, to WLAN OFDM legacy systems and the second phase is particularly suited to a multiple antenna system, such as a MIMO system. To overcome the problems in the prior systems, the Automatic Gain Control (AGC) of a receiver will perform one training during the first training phase and the AGC of the receiver will retrain during the second training phase. This will allow the receiver to 10 retrain its power measurements during the MIMO phase in order to ensure accuracy, while also allowing the receiver to be backwards compatible to WLAN systems that are not MIMO based.

FIG. 1 is a schematic block diagram of a MIMO transmitter 100. As shown in FIG. 1, the exemplary two antenna transmitter 100 encodes the information 15 bits received from the medium access control (MAC) layer and maps the encoded bits to different frequency tones (subcarriers) at stage 105. For each transmit branch, the signal is then transformed to a time domain wave form by an IFFT (inverse fast Fourier transform) 115. A guard interval (GI) of 800 nanoseconds (ns) is added in the exemplary implementation before every OFDM symbol by stage 120 and a preamble 20 of 32 μ s is added by stage 125 to complete the packet. The digital signal is then pre-processed at stage 128 and converted to an analog signal by converter 130 before the RF stage 135 transmits the signal on a corresponding antenna 140.

FIG. 2 is a schematic block diagram of a MIMO receiver 200. As shown in FIG. 2, the exemplary two antenna receiver 200 processes the signal 25 received on two receive antennas 255-1 and 255-2 at corresponding RF stages 260-1, 260-2. The analog signals are then converted to digital signals by corresponding converters 265. The receiver 200 processes the preamble to detect the packet, and then extracts the frequency and timing synchronization information at synchronization stage 270 for both branches. The guard interval is removed at stage 275. The signal 30 is then transformed back to the frequency domain by an FFT at stage 280. The channel estimates are obtained at stage 285 using the long training symbol. The

channel estimates are applied to the demapper/decoder 290, and the information bits are recovered.

FIG. 3 illustrates a conventional frame format 300 in accordance with the IEEE 802.11a/g standards. As shown in FIG. 3, the frame format 300 comprises 5 ten short training symbols, t1 to t10, collectively referred to as the Short Preamble. Thereafter, there is a Long Preamble, consisting of a protective Guard Interval (GI2) and two Long Training Symbols, T1 and T2. A SIGNAL field is contained in the first real OFDM symbol, and the information in the SIGNAL field is needed to transmit general parameters, such as packet length and data rate. The Short Preamble, Long 10 Preamble and Signal field comprise a legacy header 310. The OFDM symbols carrying the DATA follows the SIGNAL field.

The preamble includes two parts, the training part and the signal field. The training part allows the receiver 200 to perform packet detection, power measurements for automatic gain control (AGC), frequency synchronization, timing 15 synchronization and channel estimation. The signal field is going to be transmitted in the lowest rate and gives information, for example, on data rate and packet length. In the MIMO system, the signal field should also indicate the number of spatial streams and the number of transmit antennas 140.

The receiver 200 uses the preamble to get all the above information in 20 the preamble. Based on this information, when the data arrives, the receiver 200 removes the GI and transforms the data into the frequency domain using FFT, de-interleaves and decodes the data.

As previously indicated, in a MIMO system, besides these functions, it is also preferred that the preamble be backwards compatible with the legacy 25 802.11a/g devices, i.e., the legacy device should be able to get correct information about the duration of the packet so that it can backoff correctly and does not interrupt the MIMO HT transmission.

It is noted that there are three techniques for achieving orthogonality in 30 a multiple antenna system. In particular, orthogonality may be achieved using (i) time diversity, (ii) cyclic delay diversity (CDD), or (iii) tone interleaving (across frequency). FIG. 4 illustrates an exemplary backward compatible preamble design

400 based on CDD. As shown in FIG. 4, the legacy short training, long training, legacy signal field and high throughput (HT) signal field are all transmitted in a CDD fashion, as discussed below in conjunction with FIG. 5.

FIG. 5 illustrates the generation of a CDD signal by putting the last Δ samples of the OFDM symbol to the beginning. Different antennas have different cyclic delays. Then following the signal fields are the MIMO training fields. In this design, the legacy training fields are reused for MIMO purpose, then, only MIMO long training is needed. The MIMO long training fields are also CDD constructed such that different transmit antennas add different phase shifts to the signal.

In the embodiment of FIG. 5, the samples on the second transmit branch are cyclically shifted and corresponding Guard Intervals (GI) are added on transmit branches Tx-1 and Tx-2. As shown in FIG. 5, such a cyclic rotation can be achieved, for example, by putting the last samples of duration D of one OFDM symbol (still without guard interval, GI) before the rest of the symbol. Then, the guard interval, reusing the last G samples (0.8 microseconds in 802.11a OFDM) from the newly created symbol (shown as A' in FIG. 5), is added. This cyclic rotation is done for all OFDM symbols across the whole packet per OFDM symbol including the preambles.

It is noted that the Short Preamble in IEEE 802.11a OFDM doesn't have an explicit Guard interval, so there, the cyclic rotation should be taken across all ten Short Preamble symbols that form the Short Preamble, and no GI subsequent addition step is required. Alternatively, it can be carried out individually per each one of the ten Short Training segments (due to periodicity, there is no difference). For the Long Preamble, the rotation should take place per each one of the two Long Training Sequences or across both at the same time, again there is no difference. Then, the (long) GI should be based on the newly constructed Long Training Sequence.

The problem with the design 400 of FIG. 4 is that the AGC power measurement of the legacy short training is not accurate compared to the MIMO training and data received power. There is typically 6dB measurement error that needs to increase the dynamic range of the A/D 265 by one bit. This not only increases the A/D cost but also increases the dynamic range of all the analog and digital circuits. It

is noted that the preamble format 400 of FIG. 4 uses the first Long Preamble in the legacy header for MIMO channel estimation.

FIG. 6 illustrates an alternate preamble design 600 that reuses the legacy preamble based on tone interleaving. In this design, the preamble is not transmitted in a CDD fashion across antennas (as in FIG. 4) but rather, is transmitted using tone interleaving. Different tones of the legacy preamble and legacy and HT signal fields are transmitted on different transmit antennas, such that a subcarrier (tone) is active on only one transmit branch at a time. In the MIMO long training part, the tones are alternated across the antennas so that all the tones are trained with the MIMO long training and legacy long training. This design 600 solves the problem of the accuracy of power measurement. However, it is not fully backward compatible with some existing vendors using certain receiver algorithms. It is noted that the preamble format 600 of FIG. 6 uses the first Long Preamble in the legacy header for MIMO channel estimation.

If the MIMO preamble is not backward compatible, however, then MAC layer protection mechanism, such as Request-to-Send/Clear-to-Send (RTS/CTS) has to be used. If this is the case, then a dedicated MIMO preamble can be designed just to optimize the MIMO system performance. The present invention provides both backwards compatible preamble design and a preamble design with RTS/CTS.

20 MIMO Preamble with RTS/CTS Protection

FIG. 7 illustrates a MIMO preamble design 700 with RTS/CTS protection. As shown in FIG. 7, the preamble format 700 includes 10 tone-interleaved short training symbols, each $0.8\mu\text{s}$ in the exemplary embodiment, for packet detection, AGC and coarse frequency offset estimation. Then, tone-interleaved long training symbols are used for fine timing synchronization, fine frequency synchronization and channel estimation. Following the first long training symbols is the high throughput signal field. The signal field signals, for example, the number of special streams and number of antennas. Additional long training fields are then sent, if necessary. The number of long training fields equals the number of spatial streams or the number of the transmit antennas. The data is then sent after all the long training fields. The

preamble format 700 of FIG. 7 is not backwards compatible (since it does not contain a legacy signal field).

Backwards Compatible Preamble Format

FIG. 8 illustrates a preamble design 800 incorporating features of the 5 present invention that is backwards compatible with 802.11a/g legacy devices. The preamble design 800 provides a dedicated legacy portion 810 with a signal field for backward compatibility and a dedicated MIMO training portion 820 for performance of the MIMO system.

In the preamble design 800, the transmitter 100 first transmits the 10 legacy 802.11a/g preamble 810 using CDD. The legacy preamble 810 performs the packet detection and coarse frequency offset estimation. The results of these two functions are also going to be used in the MIMO transmission. Besides these two functions, the legacy preamble 810 is also used to perform legacy AGC, timing and frequency synchronization and channel estimation. The receiver 200 then decodes the 15 following legacy and HT signal fields. The HT signal field is also transmitted using CDD. As shown in FIG. 8, following the legacy and HT signal fields is a MIMO short training field 830 and then the MIMO long training fields. The MIMO short training field 830 is used only to adjust the AGC setting, and the length can be much shorter than the legacy short training field. As illustrated here, the MIMO short 20 training field includes a 0.8 μ s guard interval and a 1.6 μ s training symbol for the accurate power measurement.

It is noted that the preamble format 800 of FIG. 8 does not use the first Long Preamble in the legacy header for MIMO channel estimation. The dedicated short training symbol 830 allows precise power measurement for MIMO, at the 25 expense of higher preamble overhead (9.6 μ s extra). Hence, the preamble format 800 provides low dynamic range requirements (ten bit ADC).

The MIMO long training fields of FIG. 8 are transmitted on the same frequency grid as the data, as discussed below in conjunction with FIG. 11. Thus, Frequency Domain Channel Estimation (FDE) may be performed.

30 The short training field 830 of FIG. 8 is constructed in a tone-interleaved fashion, as shown in FIG. 9. FIG. 9 illustrates an exemplary design 900

for the short training symbol 830 to measure MIMO power (AGC). While an OFDM symbol with 12 tones (i.e., 0.8μs long) would be sufficient to provide accurate power across four antennas, a 24-tone OFDM symbol (i.e. 1.6μs long) provides even more accuracy, at the expense of slightly larger overhead. The populated tones are 5 interleaved across the transmit antennas, as shown in FIG. 9 for the case of two antennas. Dashed tones are transmitted from antenna # 1, and solid tones are transmitted from antenna # 2.

Since the short training symbol 830 is only 1.6μs long, only 24 tones are used (of 64 total available tones). The indices of those tones are all multiples of 10 four, so that the resulting time domain signal has a period of 1.6μs. In the exemplary two antenna case, only half of the tones are transmitted on each transmitter antenna, i.e., every other used tone is transmitted on the first antenna and the rest of tones are transmitted on the second antenna. Moreover, this short training symbol 830 can be further shortened to 0.8μs, which only uses 12 tones, to reduce the overhead.

15 FIG. 10 shows the architecture for generating the short training symbol 830 of FIG. 8 at the transmitter 100. As shown in FIG. 10, the active dashed tones are transmitted from antenna 1 (TX-1), and solid tones are transmitted from antenna 2 (TX-2). For each transmit branch, the active tones are transformed to a time domain wave form by an IFFT (inverse fast Fourier transform) 1010, the time domain signals 20 are then converted to a serial stream at stage 1020, and the digital signal is upconverted to an RF signal at stage 1030 prior to transmission from each antenna (TX).

The MIMO long training fields of FIG. 8 are transmitted after the short 25 training symbol 830. In the preamble format 800, since the AGC is readjusted, the legacy long training field cannot be reused for the MIMO purpose. The number of long training fields is equal to the number of spatial streams or number of the transmit antennas. Each long training filed is constructed in a tone interleaved way, with the first long training symbol using even/odd tones and the second long training symbol using odd/even tones in the exemplary embodiment.

30 FIG. 11 illustrates an exemplary design 1100 for the first long training symbol of FIG. 8 in the exemplary two transmit branch implementation (or two

spatial streams case). The exemplary design 1100 employs 48 tones. The even tones are transmitted on the first transmit antenna and the odd tones are transmitted on the second transmit antenna in the first long training field.

FIG. 12 illustrates an exemplary design 1200 for the second long training symbol of FIG. 8 in the exemplary two transmit branch implementation (or two spatial streams case). The exemplary design 1200 employs 48 tones. The odd tones are transmitted on the first transmit antenna and the even tones are transmitted on the second transmit antenna in the second long training field.

In this way, all the tones on all the transmit antennas or spatial streams are covered after all the long training fields. In the case of more transmit antennas or spatial streams, in the same long training field, different antennas transmit different tones. The tones are alternated among antennas in different training fields to ensure that all the tones are covered by the training. The MIMO long training fields are used for the fine timing synchronization, fine frequency synchronization and channel estimation.

FIGS. 13 and 14 illustrate preamble designs 1300, 1400, incorporating features of the present invention that for exemplary three and four transmit antenna implementations, respectively. Generally, for each additional transmit antenna (or spatial stream), the preamble format is extended to include an additional guard interval and long training symbol (comprised of two 3.2 μ s long OFDM symbols).

Further Backward Compatible Designs

FIG. 15 illustrates another backward compatible preamble design 1500. The preamble format 1500 has two parts, the legacy 1510 preamble concatenated with the MIMO training portion 1520. The difference here is that the long training field uses only one OFDM symbol but with 128 tones in a 20MHz band or 256 tones in a 40MHz band (symbol time remains 6.4us in either case). Only one such long training field (having two OFDM symbols) is needed for the exemplary two transmit antenna implementation (two such long training fields are needed for three and four transmit antenna implementations). In the preamble design 1500, all the MIMO channels are estimated based on this one long training field. Time domain channel estimation or other frequency domain interpolation channel estimation

schemes have to be used. The drawback of this kind of channel estimation scheme is the robustness of the performance. The channel estimation scheme could be sensitive to the channel delay profiles.

Generally, the preamble design 1500 reduces the preamble overhead 5 by concatenating two 64-point OFDM symbols into one 128-point symbol. The preamble design 1500 does not include the 0.8us guard interval, due to the two 128 point FFTs (thus requiring time domain channel estimation, which is more complex than performing Frequency Domain channel estimation (FDE)). It is noted that FDE cannot be performed since data symbols are on the 64-point frequency grid, whereas 10 the long training symbol is on a 128-point frequency grid in the exemplary embodiment. If the data is on a 128 point FFT grid, then the 0.8us GI is required.

In an implementation having four transmit antennas, the 128-point FFT gets replaced by a 256 point FFT and the OFDM symbol time increases to 12.8us. This will save 2.4us from the preamble (assuming that the data is 64 points).

15 FIG. 16 illustrates another preamble design 1600 incorporating features of the present invention that reduces the length of the preamble. In the preamble design 1600, only one long training field (having two OFDM symbols) is transmitted. In this manner, only some of the tones are covered by the training, and the other tones have to be interpolated. While the performance of such a design 1600 20 is not robust, it could be helpful for certain applications, such as Voice over IP (VoIP), where the performance requirement is low while the packet is short.

SVD Preamble Design

FIG. 17 is a schematic block diagram of a transmitter 1700 that 25 extends the preamble formats of the present invention for SVD-MIMO (Singular Value Decomposition MIMO). In an SVD mode, a steering matrix is applied to map the spatial streams to the transmit antennas, as shown in FIG. 17. FIG. 17 operates in a similar manner to FIG. 1, except for the introduction of the spatial steering matrix that varies the signal in the spatial domain.

30 FIG. 18 illustrates a preamble format 1800 incorporating features of the present invention for SVD-MIMO. Generally, the preamble 1800 needs more adjustment to maintain the system performance. In the preamble 1800, the MIMO

short training needs to be much longer because each tone in SVD mode has different power scaling. In the exemplary format 1800 shown in FIG. 18, a $3.2\mu\text{s}$ preamble is used for the AGC measurement which uses all 52 tones. The 52 tones are interleaved across all the spatial streams, and the corresponding steering matrix (from FIG. 17) is applied to each tone to form the training symbol that is sent on the transmit antennas. Depending on the performance requirement and channel delay profile, more than one such short training symbol may be needed. The tones in the long training field are going to be interleaved across the spatial streams first, as discussed below in conjunction with FIGS. 13 and 14, and then the steering matrices are applied to map to the transmit antennas.

Hybrid Preamble Design

FIG. 19 illustrates a hybrid preamble design 1900 incorporating features of the present invention. The hybrid preamble design 1900 recognizes that the preamble designs discussed above in conjunction with FIGS. 4, 13-16, and 18 all have a common legacy preamble part followed by a legacy signal field and an HT signal field. Their difference lies in the following MIMO training part. Thus, the HT signal field can be used to signal the MIMO training format, as shown in FIG. 19. For longer packets, such as associated with video transmissions, the preamble design of FIGS. 13 and 14 can be used, having a longer preamble but demonstrating better performance. For shorter packets, such as associated with VoIP, the preamble design of FIG. 16 can be used, having shorter preambles and overhead. For such a design, only one or two bits are needed in the HT signal field to signal the preamble training format, as shown in FIG. 19.

It is to be understood that the embodiments and variations shown and described herein are merely illustrative of the principles of this invention and that various modifications may be implemented by those skilled in the art without departing from the scope and spirit of the invention.

We claim:

1. A method for transmitting data in a multiple antenna communication system having N transmit antennas, said method comprising the step of:
 - 5 transmitting a legacy preamble having at least one legacy long training field and an extended portion having at least N additional long training fields on each of said N transmit antennas.
2. The method of claim 1, wherein said legacy preamble further
 - 10 comprises at least one short training symbol and one SIGNAL field.
3. The method of claim 1, wherein said N additional long training fields are tone interleaved across said N transmit antennas.
- 15 4. The method of claim 1, wherein said extended portion further includes a short training field for power estimation.
5. The method of claim 1, wherein said extended portion further includes a signal field identifying a preamble format.
- 20 6. A transmitter in a multiple antenna communication system, comprising:
N transmit antennas for transmitting a legacy preamble having at least one legacy long training field and an extended portion having at least N additional
25 long training fields on each of said N transmit antennas.
7. The transmitter of claim 6, wherein said legacy preamble further comprises at least one short training symbol and one SIGNAL field.

8. A method for receiving data on at least one receive antenna transmitted by a transmitter having N transmit antennas in a multiple antenna communication system, said method comprising the steps of:

5 receiving a legacy preamble having at least one legacy long training field and an extended portion having at least N additional long training fields on each of said N transmit antennas.

9. The method of claim 8, wherein said N additional long training fields are tone interleaved across said N transmit antennas.

10

10. A receiver in a multiple antenna communication system having at least one transmitter having N transmit antennas, comprising:

15 at least one receive antenna for receiving a legacy preamble having at least one legacy long training field and an extended portion having at least N additional long training fields on each of said N transmit antennas.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US2005/014407

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 H04B7/06 H04L27/26

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 H04B H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

INTERNATIONAL SEARCH REPORTInternational application No.
PCT/US2005/014407**Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)**

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:

2. Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1, 2, 5-8, 10

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1,2,5-8,10

Independent claim 1 relates to a method for transmitting data in a multiple antenna communication system having N transmit antennas comprising transmitting a legacy preamble having at least one legacy long training field and an extended portion having at least N additional long training fields on each of said N transmit antennas.

Independent claims 6, 8 and 10 relate to the corresponding transmitter, receiving method and receiver, respectively. Claims 2 and 7 depending on claims 1 and 6, respectively, state that the legacy preamble further comprises at least one short training symbol and one signal field.

1.1. claim: 5

Claim 5 depending on claim 1 states that the extended portion further includes a signal field identifying a preamble format.

2. claims: 3, 9

Claims 3 and 9 depending on claims 1 and 8, respectively, state that the N additional long training fields are tone interleaved across said N transmit antennas.

3. claim: 4

Claim 4 depending on claim 1 states that the extended portion further includes a short training field for power estimation.
