REFERENCES TO RELATED APPLICATIONS

[0001] The present application claims priority to U.S. Provisional Application No. 61/581,053, filed December 28, 2011, and U.S. Provisional Application No. 61/661,320, filed June 18, 2012, the entirety of which are incorporated herein by reference.

FIELD OF THE INVENTION

[0002] The present invention generally relates to substituted benzaldehydes and derivatives thereof that act as allosteric modulators of hemoglobin, methods and intermediates for their preparation, pharmaceutical compositions comprising the modulators, and methods for their use in treating disorders mediated by hemoglobin and disorders that would benefit from increased tissue oxygenation.

BACKGROUND OF THE INVENTION

[0003] Hemoglobin (Hb) is a tetrameric protein in red blood cells that transports up to four oxygen molecules from the lungs to various tissues and organs throughout the body. Hemoglobin binds and releases oxygen through conformational changes, and is in the tense (T) state when it is unbound to oxygen and in the relaxed (R) state when it is bound to oxygen. The equilibrium between the two conformational states is under allosteric regulation. Natural compounds such as 2,3-bisphosphoglycerate (2,3-BPG), protons, and carbon dioxide stabilize hemoglobin in its de-oxygenated T state, while oxygen stabilizes hemoglobin in its oxygenated R state. Other relaxed R states have also been found, however their role in allosteric regulation has not been fully elucidated.

[0004] Sickle cell disease is a prevalent disease particularly among those of African and Mediterranean descent. Sickle hemoglobin (HbS) contains a point mutation where glutamic acid is replaced with valine, allowing the T state to become susceptible to polymerization to give the HbS containing red blood cells their characteristic sickle shape. The sickled cells are also more rigid than normal red blood cells, and their lack of flexibility can lead to blockage of blood vessels. Certain synthetic aldehydes have been found to shift the equilibrium from
the polymer forming T state to the non-polymer forming R state (Nnamani et al. Chemistry & Biodiversity Vol. 5, 2008 pp. 1762-1769) by acting as allosteric modulators to stabilize the R state through formation of a Schiff base with an amino group on hemoglobin.

[0005] US 7,160,910 discloses 2-furfuraldehydes and related compounds that are also allosteric modulators of hemoglobin. One particular compound 5-hydroxymethyl-2-furfuraldehyde (5HMF) was found to be a potent hemoglobin modulator both \textit{in vitro} and \textit{in vivo}. Transgenic mice producing human HbS that were treated with 5HMF were found to have significantly improved survival times when exposed to extreme hypoxia (5% oxygen). Under these hypoxic conditions, the 5HMF treated mice were also found to have reduced amounts of hypoxia-induced sickled red blood cells as compared to the non-treated mice.

[0006] A need exists for therapeutics that can shift the equilibrium between the deoxygenated and oxygenated states of Hb to treat disorders that are mediated by Hb or by abnormal Hb such as HbS. A need also exists for therapeutics to treat disorders that would benefit from having Hb in the R state with an increased affinity for oxygen. Such therapeutics would have applications ranging, for example, from sensitizing hypoxic tumor cells that are resistant to standard radiotherapy or chemotherapy due to the low levels of oxygen in the cell, to treating pulmonary and hypertensive disorders, and to promoting wound healing.

Compounds that have the same molecular formula but differ in the nature or sequence of bonding of their atoms or the arrangement of their atoms in space are termed "isomers". Isomers that differ in the arrangement of their atoms in space are termed "stereoisomers". "Stereoisomer" and "stereoisomers" refer to compounds that exist in different stereoisomeric forms if they possess one or more asymmetric centers or a double bond with asymmetric substitution and, therefore, can be produced as individual stereoisomers or as mixtures. Stereoisomers include enantiomers and diastereomers. Stereoisomers that are not mirror images of one another are termed "diastereomers" and those that are non-superimposable mirror images of each other are termed "enantiomers". When a compound has an asymmetric center, for example, it is bonded to four different groups, a pair of enantiomers is possible. An enantiomer can be characterized by the absolute configuration of its asymmetric center and is described by the R- and S-sequencing rules of Cahn and Prelog, or by the manner in which the molecule rotates the plane of polarized light and designated as dextrorotatory or levorotatory (i.e., as (+) or (-)-isomers respectively). A chiral compound can exist as either individual enantiomer or as a mixture thereof. A mixture containing equal proportions of the enantiomers is called a "racemic mixture". Unless otherwise indicated, the description is intended to include individual stereoisomers as well as mixtures. The methods for the determination of stereochemistry and the separation of stereoisomers are well-known in the art (see discussion in Chapter 4 of ADVANCED ORGANIC CHEMISTRY, 4th edition J. March, John Wiley and Sons, New York, 1992) differ in the chirality of one or more stereocenters.

The compounds of the present invention may also contain unnatural proportions of atomic isotopes at one or more of the atoms that constitute such compounds. For example, the compounds may be radiolabeled with isotopes, such as for example deuterium (2H), tritium (3H), iodine-125 (125I) or carbon-14 (14C). All isotopic variations of the compounds of the present invention, whether radioactive or not, are intended to be encompassed within the scope of the present invention.

Unless indicated otherwise, the nomenclature of substituents that are not explicitly defined herein are arrived at by naming the terminal portion of the functionality followed by the adjacent functionality toward the point of attachment. For example, the substituent "alkoxyalkyl" refers to an alkyl group that is substituted with alkoxy and "hydroxyalkyl" refers to an alkyl group that is substituted with hydroxy. For both of these substituents, the point of attachment is at the alkyl group.
It is understood that the definitions and formulas provided herein are not intended to include impermissible substitution patterns (e.g., methyl substituted with 5 fluoro groups). Such impermissible substitution patterns are well known to the skilled artisan.

subembodiments as disclosed herein including any combination of elements disclosed herein including the a selection of any single elements.

[0110] In one group of embodiments, provided is a pharmaceutical composition comprising a compound of any of the above embodiments or a tautomer or pharmaceutically acceptable salt thereof.

[0111] In one group of embodiments, provided is a pharmaceutical composition comprising a compound that is

or a pharmaceutically acceptable salt thereof.

[0112] The compounds of the present invention may be prepared by known organic synthesis techniques, including the methods described in more detail in the Examples.

[0113] In one group of embodiments, provided is an intermediate compound used in the preparation of the compounds disclosed herein.

[0114] In one group of embodiments, provided are methods for preparing the compounds disclosed herein.

[0115] For example, Scheme I shows a synthetic route for the synthesis of the compounds of Formula (I) where X is O and Y is C¼. Phenol 1.1 is contacted with intermediate 1.2 in the presence of base under ether forming conditions to give ether 1.3, where Lg represents a leaving group such as a halogen leaving group. Conversely, when X is O and Y is CH₂, the compounds of Formula (I) can be prepared using the appropriate starting materials where the OH moiety of intermediate 1.1 is replaced with a leaving group and the Lg group of intermediate 1.2 is replaced with an OH group.
Scheme I

[0116] Scheme II shows an example of a synthetic route for the synthesis of the compounds of Formula (I) where X and Y are CH₂. Alkene 2.1 is contacted with alkene 2.2 under metathesis forming conditions in the presence of an appropriate transition metal catalyst. Suitable catalysts include ruthenium catalysts such as Grubbs’ catalyst. Product 2.3 is then hydrogenated to give compound 2.4.

Scheme II

[0117] Scheme III shows an example of a synthetic route for the synthesis of the compounds of Formula (I) where R⁶ together with R¹b form a cyclic ether. Compound 3.1, is reacted with diethylphosphite and a base such as sodium methoxide to give intermediate 3.2, that is then condensed with aldehyde 3.3 to give alkene 3.4. Treatment of the alkene with H₂ under hydrogenation conditions gives lactone 3.4, which is then reduced with a suitable reducing agent such as LiBH₄Et₃ to give cyclic hemiacetal 3.5.
Scheme III

[0118] Scheme IV shows an example of synthesis of the compounds of Formula (I) where Q is pyridine-3-yl and R₈ heteroaryl. Acid 4.1 is reduced to alcohol 4.2 using known methods such as by forming the anhydride (e.g. treatment with triethylamine and /-butyl chloroformate) followed by reduction with NaB₄. Alcohol 4.2 is converted to chloride 4.3 such as by treatment with thionyl chloride. Coupling of the halide with alcohol 4.4 under ether forming conditions gives the precursor 4.5 that can be functionalized with a variety to heteroaryl R₈ groups. For example, 4.5 can be coupled with pyrazole 4.6 under known organometallic coupling conditions (e.g. Pd[P₄[P₄]₄) to give 4.7, where PG is a nitrogen protecting group such as a silyl protecting group that can be removed to give the product 4.8.
One skilled in the art will recognize that in certain embodiments it may be advantageous to use a protecting group strategy. The protecting group can be removed using methods known to those skilled in the art.

In one group of embodiments, certain of the compounds disclosed herein may generally be utilized as the free base. Alternatively, certain of the compounds may be used in the form of acid addition salts.

It is understood that in another group of embodiments, any of the above embodiments may also be combined with other embodiments listed herein, to form other embodiments of the invention. Similarly, it is understood that in other embodiments, listing of groups includes embodiments wherein one or more of the elements of those groups is not included.
III. Compositions and Methods of Administration

Depending on the intended mode of administration, the pharmaceutical compositions may be in the form of solid, semi-solid or liquid dosage forms, preferably in unit dosage form suitable for single administration of a precise dosage. In addition to an effective amount of the active compound(s), the compositions may contain suitable pharmaceutically-acceptable excipients, including adjuvants which facilitate processing of the active compounds into preparations which can be used pharmaceutically. "Pharmaceutically acceptable excipient" refers to an excipient or mixture of excipients which does not interfere with the effectiveness of the biological activity of the active compound(s) and which is not toxic or otherwise undesirable to the subject to which it is administered.

For solid compositions, conventional excipients include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talc, cellulose, glucose, sucrose, magnesium carbonate, and the like. Liquid pharmacologically administrable compositions can, for example, be prepared by dissolving, dispersing, etc., an active compound as described herein and optional pharmaceutical adjuvants in water or an aqueous excipient, such as, for example, water, saline, aqueous dextrose, and the like, to form a solution or suspension. If desired, the pharmaceutical composition to be administered may also contain minor amounts of nontoxic auxiliary excipients such as wetting or emulsifying agents, pH buffering agents and the like, for example, sodium acetate, sorbitan monolaurate, triethanolamine sodium acetate, triethanolamine oleate, etc.

For oral administration, the composition will generally take the form of a tablet or capsule, or it may be an aqueous or nonaqueous solution, suspension or syrup. Tablets and capsules are preferred oral administration forms. Tablets and capsules for oral use will generally include one or more commonly used excipients such as lactose and corn starch. Lubricating agents, such as magnesium stearate, are also typically added. When liquid suspensions are used, the active agent may be combined with emulsifying and suspending excipients. If desired, flavoring, coloring and/or sweetening agents may be added as well. Other optional excipients for incorporation into an oral formulation include preservatives, suspending agents, thickening agents, and the like.

Injectable formulations can be prepared in conventional forms, either as liquid solutions or suspensions, solid forms suitable for solubilization or suspension in liquid prior to injection, or as emulsions or liposomal formulations. The sterile injectable formulation
may also be a sterile injectable solution or a suspension in a nontoxic parenterally acceptable diluent or solvent. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils, fatty esters or polyols are conventionally employed as solvents or suspending media.

[0126] The pharmaceutical compositions of this invention may also be formulated in lyophilized form for parenteral administration. Lyophilized formulations may be reconstituted by addition of water or other aqueous medium and then further diluted with a suitable diluent prior to use. The liquid formulation is generally a buffered, isotonic, aqueous solution. Examples of suitable diluents are isotonic saline solution, 5% dextrose in water, and buffered sodium or ammonium acetate solution. Pharmacologically acceptable solid or liquid excipients may be added to enhance or stabilize the composition, or to facilitate preparation of the composition.

[0127] Typically, a pharmaceutical composition of the present invention is packaged in a container with a label, or instructions, or both, indicating use of the pharmaceutical composition in the treatment of the indicated disease.

[0128] The pharmaceutical composition may additionally contain one or more other pharmacologically active agents in addition to a compound of this invention.

[0129] Dosage forms containing effective amounts of the modulators are within the bounds of routine experimentation and within the scope of the invention. A therapeutically effective dose may vary depending upon the route of administration and dosage form. The representative compound or compounds of the invention is a formulation that exhibits a high therapeutic index. The therapeutic index is the dose ratio between toxic and therapeutic effects which can be expressed as the ratio between LD_{50} and ED_{50}. The LD_{50} is the dose lethal to 50% of the population and the ED_{50} is the dose therapeutically effective in 50% of the population. The LD_{50} and ED_{50} are determined by standard pharmaceutical procedures in animal cell cultures or experimental animals. It should be understood that a specific dosage and treatment regimen for any particular patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health, sex and diet of the patient, and the time of administration, rate of excretion, drug combination, judgment of the treating physician and severity of the particular disease being treated. The amount of active ingredient(s) will also depend upon the particular compound and other therapeutic agent, if present, in the composition.

Referring to the examples that follow, compounds of the present invention were synthesized using the methods described herein, or other methods known in the art.

Example 1. Preparation of 2-(imidazo[1,5-a]pyridin-8-ylmethoxy)-5-methoxybenzaldehyde

Step 1:

To a cold solution of 3-ethoxycarbonylpyridine (25 g, 165.4 mmol, 1 eq) in DCM was slowly added mCPBA (70% wt, 198.5 mmol) and the reaction mixture was stirred at rt overnight. Reaction was cooled and diluted with DCM and then neutralized with slow addition of sat. NaHCO$_3$. Aqueous layer was washed with DCM (3X) and the combined organic layer was dried and evaporated to give a residue, which was purified by column chromatography (EtOAc/MeOH) to give 3-ethoxycarbonylpyridine N-oxide (13.6 g). MS: exact mass calculated for C$_9$H$_8$NO$_3$, 167.06; m/z found, 168 [M+H]$^+$. 

Step 2:
To a solution of 3-ethoxycarbonylpyridine N-oxide in 330 mL of DCM were added trimethylsilyl cyanide (TMSCN) (11.0 g, 65.9 mmol, 1.0 eq) and dimethylcarbamoyl chloride (7.1 g, 65.9 mmol, 1.0 eq) and the reaction mixture was stirred at rt for 2 days. Then 10% K$_2$CO$_3$ was slowly added to make the reaction mixture basic. Organic layer was separated, dried and evaporated to provide the crude, which was purified by column chromatography to provide compounds A (5.7 g) and B (3.5 g).

Steps 3 and 4:

To a solution of ethyl 2-cyano-3-pyridinecarboxylate (2.5 g) and cone. HCl (5 mL) in 150 mL ethanol was added 10% Pd/C (wet, 250 mg) and the reaction mixture was hydrogenated using a hydrogen balloon and stirred for 12 h. The reaction was filtered through celite and ethanol was evaporated to give ethyl 2-(aminomethyl)-3-pyridinecarboxylate HCl as a white solid which was used in the next step without further purification.

A mixture of 44.8 mL of acetic anhydride and 19.2 mL of formic acid was heated in a 50-60 °C oil bath temperature for 3 h and then cooled to rt to give formic-acetic anhydride, which was then slowly added to the solid ethyl 2-(aminomethyl)-3-pyridinecarboxylate HCl and then stirred at rt for 8 h. Excess reagent was evaporated to give a residue, which was neutralized by very slow addition of sat. NaHC0$_3$ solution. Solution was extracted with DCM, dried and evaporated to provide ethyl imidazo[1,5-a]pyridine-8-carboxylate as a yellow solid (crude weight 2.7 g). MS: exact mass calculated for C$_{10}$H$_{10}$N$_2$O$_2$, 190.07; m/z found, 191 [M+H$^+$].

Steps 5 and 6:
To a cold solution of lithium aluminum hydride (1.62 g, 42.4 mmol, 4.0 eq) in THF (50 mL) was added the crude ethyl imidazo[1,5-a]pyridine-8-carboxylate (2.7 g, 14.2 mmol, 1.0 eq) and the reaction mixture was heated at reflux for 2 h. The reaction was cooled and water (1.7 mL), 15% NaOH (1.7 mL) and water (5.1 mL) were slowly added. Solution was diluted with excess EtOAc and stirred at rt for 30 min. The solution was filtered and the solid was washed with ethyl acetate. Organic layers were combined, dried and solvent was removed to give crude imidazo[1,5-a]pyridine-8-methanol, which was purified by column chromatography (EtOAc/Hexane). MS: exact mass calculated for C₈H₇ClN₂, 148.06; m/z found, 149 [M+H]⁺.

To a solution of imidazo[1,5-a]pyridine-8-methanol (800 mg) in chloroform (50 mL) was slowly added thionyl chloride (10 mL) and the reaction mixture was stirred at rt for 8 h. Chloroform was removed and the residue was then taken in toluene and toluene was evaporated (3x) to give a solid, which was used in the next step without further purification. MS: exact mass calculated for C₈H₅ClN₂, 166.03; m/z found, 167 [M+H]⁺.

Step 7:

To a solution of chloride (1.25 mmol, 1.0 eq), and phenol (1.25 mmol, 1.0 eq) in DMF (10 mL) was added K₂CO₃ (3.0 eq) and the reaction mixture was heated at 80-90 °C for 5 h. Solvent was removed and the residue was purified by column chromatography (EtOAc/MeOH).NMR (400 MHz, CDCl₃): δ 3.82 (s, 3H), 5.45 (s, 2H), 6.58 (m, 1H), 6.81 (m, 1H), 7.03 (s, 1H), 7.12 (m, 1H), 7.35 (m, 1H), 7.50 (s, 1H), 7.95 (m, 1H), 8.18 (s, 1H), 10.58 (s, 1H); MS: exact mass calculated for C₁₈H₁₄ClN₂O₂, 282.10; m/z found, 283 [M+H]⁺.
Example 2. Preparation of 2-(imidazo[1,5-a]pyridin-8-ylmethoxy)-4-methoxybenzaldehyde

[0147] The title compound was prepared using 2-hydroxy-4-methoxybenzaldehyde in a similar manner as in Example 1. NMR (400 MHz, CDCl₃): δ 3.85 (s, 3H), 5.50 (s, 2H), 6.50-6.60 (m, 3H), 6.88 (s, 1H), 7.48 (s, 1H), 7.88 (m, 2H), 8.18 (s, 1H), 10.58 (s, 1H); MS: exact mass calculated for C₁₆H₁₄N₂O₃, 282.10; m/z found, 283 [M+H]^+.

Example 3. Preparation of 2-(imidazo[1,5-a]pyridin-6-ylmethoxy)-5-methoxybenzaldehyde

Steps 1 and 2:

[0148] To a solution of ethyl 6-cyano-3-pyridinecarboxylate (3.75 g) and cone. HCl (7.5 mL) in 225 mL ethanol was added 10% Pd/C (wet, 375 mg) and the reaction mixture was hydrogenated using hydrogen balloon and stirred for 12 h. Solution was filtered through celite and ethanol was evaporated to give ethyl 6-(aminomethyl)-3-pyridinecarboxylate HCl as a white solid, which was used in the next step without further purification.

[0149] A mixture of 67.2 mL of acetic anhydride and 28.8 mL of formic acid was heated at 50-60 °C oil bath temperature for 3 h and then cooled to rt to give formic-acetic anhydride, which was then slowly added into the solid ethyl 2-(aminomethyl)-3-pyridinecarboxylate HCl
and then stirred at rt for 8 h. Excess reagent was evaporated to give a residue, which was neutralized by very slow addition of sat NaHCO₃ solution. Solution was extracted with DCM, dried and evaporated to provide imidazo[l,5-a]pyridine as a yellow solid. MS: exact mass calculated for C₁₀H₁₀N₂O₂, 190.07; m/z found, 191 [M+H]+.

IN VITRO TESTING

[0230] Oxygen equilibrium curves (OEC) in purified Hemoglobin S (HbS) were measured by the change in p50, the partial pressure of oxygen at which the heme binding sites in the HbS sample are 50% saturated with oxygen. HbS was purified by a modified procedure (Antonini and Brunori, 1971; Hemoglobin and Myoglobin in their Reactions with Ligands; North Holland Publishing Company; Amsterdam, London) from blood obtained from homozygous sickle cell patients though the Hemoglobinopathy Center at Children's Hospital Oakland Research Institute (CHORI) with Institutional Review Board approval. Oxygen equilibrium curves were carried out with a HEMOX analyzer, (TCS Scientific, New Hope, PA). Five hundred µL of 250 µM purified HbS were diluted into 4.5 mL of HEMOX buffer (30 mM TES, 130 mM NaCl, 5 mM KCl, pH= 7.4) resulting in a final hemoglobin concentration of 25 µM. The compounds were added at the final desired concentrations. The mixture was incubated for 45 min at 37 °C and then transferred to the Hemox sample chamber. The samples were saturated with oxygen by flushing with compressed air for 10 minutes. The samples were then flushed with pure nitrogen and the absorbance of deoxy-Hb was recorded as a function of the solution p02. The oxygen equilibrium data was then fit to the Hill Model to obtain values for p50. The deoxygenation curves for both HbS alone (control) and HbS in the presence of compound were collected with the TCS software. The p50 for purified Hbs was typically 13.8 ± 1.6. Delta p50 values were obtained from the p50 value for control minus the p50 value for HbS treated with compound divided by the p50 value for the control. A positive delta p50 value corresponds to a left shifted curve and a lower p50 value relative to control, indicating that the compound acts to modulate HbS to increase its affinity for oxygen.

Example 34. Modulation of Hemoglobin Oxygen affinity by Substituted Benzaldehyde Compounds—Assay Results.

[0231] The compounds of Table 1 that were where tested in the assay above were all found to have positive delta p50 values. Delta p50% is calculated from [(p50(HbS) - p50(HbS treated with compound))/p50(HbS)] X 100. Table 2 below lists the delta p50% values where + indicates a delta p50% of between 0 and 29 and ++ indicates a delta p50% of 30 or greater. Unless noted otherwise, the compounds in Table 2 were tested at 30µM.

Example 35. Polymerization Assay.

Polymerization assays are carried out in vitro using purified HBS exchanged into 1.8 M potassium phosphate buffer at pH 7.4. Using a slightly modified protocol (Antonini and Brunori, 1971), HbS is purified by the CRO VIRUSYS, from blood obtained from homozygous sickle cell patients through the Hemoglobinopathy Center at Children's Hospital Oakland Research Institute (CHORI) with Institutional Review Board approval. Compounds are prepared in 100% DMSO and a desired amount is added to 50 µM of purified HBS at a final DMSO concentration of 0.3%. Final potassium phosphate concentration is adjusted to 1.8 M using a combination of 2.5 M potassium phosphate stock solution and water at pH 7.4. The reaction mixture is incubated for an hour at 37 °C and then transferred into a 24-well plate for deoxygenation in a glove box containing 99.5 % nitrogen and 0.5% oxygen. The 24-well plate is not covered and incubated at 4 °C on a plate cooler inside the glove box for one and a half hours. Fifty µL of the reaction mixture is transferred into a 96-well plate and the absorbance at 700 nm is measured every minute for one hour at 37 °C in a plate reader located inside the glove box. A plot of the absorbance against time is fitted using a Boltzman sigmoidal fit and the delay time (from zero to time at half Vmax) is measured. To compare and rank compounds, delay times are expressed as percent delay (%DT), which is defined as the difference in delay times for HBS/compound and HBS alone multiplied by 100 and divided by the delay time for HBS alone.

Compounds listed below have been tested in the polymerization assay. Activity ranges are defined by the number of dagger (†) symbols indicated. † denotes activity > 40%
but ≤ 80%; † † denotes activity > 80% but ≤ 120%; † † † denotes activity > 120% but ≤ 140%; † † † † denotes activity > 160%.

Example 36. R/T Assay

[0234] A relaxed-to-tense transition assay (“R/T assay”) was used to determine the ability of substituted benzaldehyde compounds to maintain the high-oxygen affinity relaxed (R) state of hemoglobin under deoxygenated conditions. This ability can be expressed as a “delta R” value (i.e., the change in the time-period of the R state after hemoglobin is treated with a compound, as compared to the period without treatment with the compound). Delta R is the %R to remaining after the compounds treatment compared with no treatment (e.g. if R% without treatment is 8% while with treatment with a target compound is 48% R at 30 µM, then %R is 40% for that compound.

[0235] A mixture of HbS/A was purified from blood obtained from homozygous sickle cell patients though the Hemoglobinopathy Center at Children’s Hospital Oakland Research Institute (CHORI) with Institutional Review Board approval. HbS/A (at a final concentration of 3 µM) was incubated for 1 hr at 37°C in presence or absence of compounds in 50 µM potassium phosphate buffer, pH=7.4 and 30 µM 2, 3 diphosphoglycerate (DPG) in 96 well plates in a final volume of 160 µL. Compounds were added at different concentrations (3 µM to 100 µM final concentrations). Plates were covered with a Mylar film. After incubation
was completed the Mylar cover was removed and the plates were placed in a Spectrostar Nano plate reader previously heated at 37°C. Five minutes later, N\textsubscript{2} (flow rate = 20 L/min) was flowed through the spectrophotometer. Spectroscopic measurements (300 nm to 700 nm) were taken every 5 min for 2 hours. Data analysis was performed by using linear regression from the data retrieved for all wavelengths.

Table 4 below lists the delta R values where + indicates a delta R of between 0 and 30, ++ indicates a delta R of between 30 and 50, and +++ indicates a delta R of 50 or greater. Unless noted otherwise, the compounds in Table 2 were tested at 9 µM.

Example 37. Whole Blood Assay

Oxygen Equilibrium Curves (OEC) of whole blood before and after treatment with different concentrations of substituted benzaldehyde compounds were performed as follows using a HEMOX analyzer (TCS Scientific, New Hope, PA). Blood samples from homozygous sickle cell patients were obtained though the Hemoglobinopathy Center at Children's Hospital Oakland Research Institute (CHORJ) with Institutional Review Board approval. The hematocrit was adjusted to 20% using autologous plasma and the blood samples were incubated for 1 hour at 37 °C in absence or presence of compounds. 100 µl of these samples were added to 5 mL of Hemox buffer (30 mM TES, 130 mM NaCl, 5 mM KCl, pH= 7.4) at 37 °C and then transferred to the Hemox sample chamber. The samples were saturated with oxygen by flushing with compressed air for 10 minutes. The samples were then flushed with pure nitrogen and the respective absorbances of oxy- and deoxy-Hb are recorded as a function of the solution pO2. The oxygen equilibrium data were then fitted to the Hill Model to obtain values for p50. The deoxygenation curves for both whole blood alone (control) and whole blood in the presence of the compound were collected with the TCS software.

Table 5 below lists the delta p50% values where + indicates a delta p50% of between 0 and 29, ++ indicates a delta p50% of between 30 and 50, and +++ indicates a delta p50% of 50 or greater. The compounds in Table 2 were tested at 1000 µM. A positive delta p50 value corresponds to a left shifted curve and a lower p50 value relative to control, indicating that the compound acts to modulate HbS to increase its affinity for oxygen.

**INTERNATIONAL SEARCH REPORT**

**Box No. II  Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)**

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following **reasons**:

1. □ Claims Nos.:
   because they relate to subject matter not required to be searched by this Authority, namely:

2. □ Claims Nos.:
   because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. X Claims Nos.: 12-17
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box No. III  Observations where unity of invention is lacking (Continuation of item 3 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

1. □ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. □ As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.

3. □ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. □ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**

□ The additional search fees were accompanied by the applicant’s protest and, where applicable, the payment of a protest fee.

□ The additional search fees were accompanied by the applicant’s protest but the applicable protest fee was not paid within the time limit specified in the invitation.

□ No protest accompanied the payment of additional search fees.
