(54) **CONNECTEUR CONCU POUR FACILITER LE SOUDAGE DE BORNES**

(54) **CONNECTOR DESIGNED TO FACILITATE THE WELDING OF TERMINALS**

(57) L'invention concerne un connecteur, conçu pour faciliter le soudage des bornes, du types de ceux présentant deux rangées de cavités sur leur partie avant destinées à recevoir les bornes d'un connecteur mâle. Deux prolongements font saillie des parties latérales du connecteur ayant une forme de prisme rectangulaire et sur leurs faces intérieures est ménagée une rainure destinée à guider une pièce en forme de "z" qui maintient et aligne dans un même plan la partie arrière des bornes femelles logées dans les cavités du connecteur pendant le soudage desdites bornes avec les extrémités des fils d'un câble multiconducteur.

(57) Connector designed to facilitate the welding of terminals, of the type having two rows of cavities in the front part thereof to receive the terminals of a male connector. The connector has a rectangular prism shape with sides from which emerge two extensions; these extensions have internal faces in which is formed a groove intended to guide a Z-shaped part which sustains and aligns in a same plane the rear portion of the female terminals housed in the connector cavities during the process of welding said terminals with the extremities of the wires of a multiconductor cable.

CONNECTOR DESIGNED TO FACILITATE THE WELDING OF TERMINALS

5 The present Patent of Invention relates more specifically to a connector whose shape characteristics allow the welding of female terminals or micro-terminals in the same plane and over a flat support zone forming a portion of same connector.

10 There are in the market and can be therefore considered as the state of the art a plurality of connectors of a noticeably prismatic configuration provided in the interior with a plurality of sockets or cavities also prismatic provided in the side walls with
15 the corresponding retention means allowing also the housing of the corresponding terminals, that same in the connection operation do not keep a rear position and after the connection with other terminals may come out from the inside of said sockets or cavities.

20 In the interior of such type of connectors are joined a great quantity of terminals, which receive, through a rear zone, the corresponding wire formed with a conductive portion and an insulating portion, whilst through the opposite portion receive the other terminal.

25 Therefore, the operation of joining in a connector the corresponding terminals with the corresponding wires is a complex operation and needing a great number of precautions for avoiding connection failures as well as that the terminals do not come out from the cavities
30 designed to that effect and which must retain them.

 The object of the present application is a connector of a noticeably prismatic configuration which major lateral bases extend as per a sort of rectangular wings in whose interior face are provided channels allowing the

- 2 -

insertion of a welding support plane formed with a support in the shape of a four and which is introduced through said channels.

5 The prismatic zone of the connector, as it is a known formula, holds a number of cavities or sockets provided with the corresponding retention means for the terminals that must lodge there.

10 The insertion of the terminals into said channels in grace to the configuration of same allows that the rear zones of said terminals meet in the welding support zone of said support, by which the welding operation itself, regardless of its nature, is enormously simplified, since it must be done in a single plane, placing the wires on top of said rear portion of the terminals for being
15 afterwards all welded in a single step.

Other details and characteristics of the present application will be manifest through the reading of the description given herebelow, in which reference is made to the figures attached to this description where the
20 above details are depicted in a rather schematic way. These details are given as an example, referring to a case of a possible practical embodiment, but is not limited to the details outlined; therefore this description must be considered from an illustrative point
25 of view and with no limitations whatsoever.

There follows a report of the several elements numbered in the drawings accompanying the present description: (10) connector, (11) body, (12) support, (13) terminal, (14) support zone, (15) wall, (16) rear
30 zone, (17) swelling, (18) guides, (19) openings, (20) mouths, (21) holes, (22) holes, (23) protuberances, (24) channels, (25) cavities.

Figure 1 is a perspective view of the connector (10) in which is mounted the support (12).

- 3 -

Figure 2 is a perspective view of the support (12), which, as can be seen, shows a support zone (14) or welding plane related with a rear zone through a wall (15) perpendicular to the support zone (14) and to the rear zone (16).

Figure 3 is a perspective view of the connector (10) free from the support (12).

In one of the preferred embodiments of what is the object of the present Patent of Invention, and as can be seen in Figure 1, the connector (10) is formed with a body (11) of noticeably prismatic configuration which minor lateral bases extend as per extensions whose interior face shows near its perimeter support guides or channels (24).

The body (11), as per a known formula, is volumetrically distributed as per a set of cavities (25) also prismatic, inside which are placed the terminals (13).

At the extensions of the minor lateral bases are provided holes (21 and 22) which serve as retention means of the support (12).

The support (12), see Figure 2, is formed with two planes (14 and 16) related through a wall (15) perpendicular to same and of little height.

In the perimetral zones of the upper or welding zone or support zone (14) are provided swellings (17) which fit into the holes (21 and 22) provided in the extensions of the lateral bases of the connector (10).

Also in the perimetral zone of the support zone (14) are provided guides (18) which fit with the channels (24) in such a way that once introduced the terminals into the interior of the cavities (25) is placed the support (12) in such a way that the guides (18) slid by the channels (24) until the front edge of the support zone (14)

- 4 -

contacts the interior portion of the body (11) of the connector (10).

5 The body (11) shows in one of its bases a row of mouths (20) by which are introduced the corresponding male terminals, not shown in the figures, making contact with the corresponding female terminals (13) situated in the interior of the cavities (25).

10 As can be seen in Figure 2, the mouths (20) had been designed in such a way that between their centers the longitudinal axis passing through same show a distance "a" and "b" of the same magnitude which in combination with the characteristics of the terminals (13) used allows, as can be seen in Figure 1, that the rear portions of said terminals (13) remain placed over the
15 plane of support or welding (14), allowing with that, as has been said above, firstly that all welding zones remain placed in the same plane, the (14), secondly that the distance between said flat zones, given the configuration of the mouths and the distances between
20 their axis "a" and "b", referred in Figure 3, allows that said rear zones of the terminals (13) keep always a constant distance, by which it will be possible to fully automate the welding operation, given that the means may work always in a flat zone and produce the welding at
25 regular intervals, in time as well as in distance.

In order to be able to fit the connector (10) in the corresponding moduli there are provided in the extension of the minor lateral bases protuberances (23) which will fit in the corresponding openings provided in said moduli
30 and not shown in the Figures attached to the present description.

The configuration of the connector (10) above described allows introducing in a first operation the terminals (13) into the cavities (25) for placing then

- 5 -

the support (12) with the help of the guides (18) and the channels (24), for proceeding then to the welding operation by any known method but in a fully automated way.

5 Enough disclosed what the present application for a Patent of Invention is in agreement with the attached figures, it's understood that can be introduced in same any detail modifications regarded as convenient, always provided that any the modifications entered do not depart
10 from the essence of the present invention as summarized in the following claims.

- 6 -

Claims

1. "IMPROVED CONNECTOR WITH ADAPTATION STEP" of those formed with a body (11) of noticeably prismatic configuration into which are disposed a series of cavities or sockets (25) also of prismatic configuration, provided with retention means for the terminals (13) which are introduced into the cavities (25) by any known system, characterized in that the body (11) extends by its minor lateral bases with extensions provided in their interior face of channels (24) por placing a support (12) provided with guiding and fitting means in said channels (24).
2. "IMPROVED CONNECTOR WITH ADAPTATION STEP" as per claim 1 characterized in that the support (12) is formed by the planes (14 and 16) related with the wall (15) perpendicular to same and of little height, provided the support (12) with the corresponding guiding and retention means.
3. "IMPROVED CONNECTOR WITH ADAPTATION STEP" as per the above claims characterized in that the support (12) shows in the edges of the support zone (14) guides (18) and swellings (17) which fit in the holes (21) and (22) provided in the extensions of the minor lateral bases.
4. "IMPROVED CONNECTOR WITH ADAPTATION STEP" as per the above claims characterized in that the distance "a" and "b" between the centers of the cavities (25) determines in combination with the terminals (13) that their rear zones remain situated in the welding support plane (14).
