Abstract: The invention relates to antigen-binding constructs comprising a protein scaffold which are linked to one or more epitope-binding domains wherein the antigen-binding construct has at least two antigen binding sites at least one of which is from an epitope binding domain and at least one of which is from a paired VH/VL domain, methods of making such constructs and uses thereof.
Antigen-binding constructs

Background

Antibodies are well known for use in therapeutic applications. Antibodies are heteromultimeric glycoproteins comprising at least two heavy and two light chains. Aside from IgM, intact antibodies are usually heterotetrameric glycoproteins of approximately 150Kda, composed of two identical light (L) chains and two identical heavy (H) chains. Typically, each light chain is linked to a heavy chain by one covalent disulfide bond while the number of disulfide linkages between the heavy chains of different immunoglobulin isotypes varies. Each heavy and light chain also has intrachain disulfide bridges. Each heavy chain has at one end a variable domain (VH) followed by a number of constant regions. Each light chain has a variable domain (VL) and a constant region at its other end; the constant region of the light chain is aligned with the first constant region of the heavy chain and the light chain variable domain is aligned with the variable domain of the heavy chain. The light chains of antibodies from most vertebrate species can be assigned to one of two types called Kappa and Lambda based on the amino acid sequence of the constant region. Depending on the amino acid sequence of the constant region of their heavy chains, human antibodies can be assigned to five different classes, IgA, IgD, IgE, IgG and IgM. IgG and IgA can be further subdivided into subclasses, IgG1, IgG2, IgG3 and IgG4; and IgA1 and IgA2. Species variants exist with mouse and rat having at least IgG2a, IgG2b. The variable domain of the antibody confers binding specificity upon the antibody with certain regions displaying particular variability called complementarity determining regions (CDRs). The more conserved portions of the variable region are called Framework regions (FR). The variable domains of intact heavy and light chains each comprise four FR connected by three CDRs. The CDRs in each chain are held together in close proximity by the FR regions and with the CDRs from the other chain contribute to the formation of the antigen binding site of antibodies. The constant regions are not directly involved in the binding of the antibody to the antigen but exhibit various effector functions such as participation in antibody dependent cell-mediated cytotoxicity (ADCC), phagocytosis via binding to Fcγ receptor, half-life/clearance rate via neonatal Fc receptor (FcRn) and complement dependent cytotoxicity via the C1q component of the complement cascade.

The nature of the structure of an IgG antibody is such that there are two antigen-binding sites, both of which are specific for the same epitope. They are therefore, monospecific.

A bispecific antibody is an antibody having binding specificities for at least two different epitopes. Methods of making such antibodies are known in the art.
Traditionally, the recombinant production of bispecific antibodies is based on the coexpression of two immunoglobulin H chain-L chain pairs, where the two H chains have different binding specificities; see Millstein et al., Nature 305 537-539 (1983), WO93/08829 and Traunecker et al/ EMBO, 10, 1991 , 3655-3659. Because of the random assortment of H and L chains, a potential mixture of ten different antibody structures are produced of which only one has the desired binding specificity. An alternative approach involves fusing the variable domains with the desired binding specificities to heavy chain constant region comprising at least part of the hinge region, CH2 and CH3 regions. It is preferred to have the CH1 region containing the site necessary for light chain binding present in at least one of the fusions. DNA encoding these fusions, and if desired the L chain are inserted into separate expression vectors and are then cotransfected into a suitable host organism. It is possible though to insert the coding sequences for two or all three chains into one expression vector. In one approach, a bispecific antibody is composed of a H chain with a first binding specificity in one arm and a H-L chain pair, providing a second binding specificity in the other arm, see WO94/04690. Also see Suresh et al Methods in Enzymology 121 , 210 , 1986. Other approaches include antibody molecules which comprise single domain binding sites which is set out in WO2007/095338.

Summary of invention

The present invention relates to an antigen-binding construct comprising a protein scaffold which is linked to one or more epitope-binding domains wherein the antigen-binding construct has at least two antigen binding sites at least one of which is from an epitope binding domain and at least one of which is from a paired VH/VL domain.

The invention further relates to antigen-binding constructs comprising at least one homodimer comprising two or more structures of formula I:

\[
(R^1)_m \quad (R^2)_n \\
(R^3)_m \quad (R^3)_n \\
\text{Constant} \quad \text{Constant} \\
\text{Light chain} \quad \text{Heavy chain} \\
(R^4)_m \quad (R^4)_n \\
X \\
(R^1)_n \\
\] (I)

wherein
X represents a constant antibody region comprising constant heavy domain 2 and constant heavy domain 3;

\[ R_1, R_4, R_7, R_8 \] represent a domain independently selected from an epitope-binding domain;

\[ R_2 \] represents a domain selected from the group consisting of constant heavy chain 1, and an epitope-binding domain;

\[ R_3 \] represents a domain selected from the group consisting of a paired VH and an epitope-binding domain;

\[ R_5 \] represents a domain selected from the group consisting of constant light chain, and an epitope-binding domain;

\[ R_6 \] represents a domain selected from the group consisting of a paired VL and an epitope-binding domain;

\( n \) represents an integer independently selected from: 0, 1, 2, 3 and 4;

\( m \) represents an integer independently selected from: 0 and 1,

wherein the Constant Heavy chain 1 and the Constant Light chain domains are associated;

wherein at least one epitope binding domain is present;

and when \( R_3 \) represents a paired VH domain, \( R_6 \) represents a paired VL domain, so that the two domains are together capable of binding antigen.

The invention relates to IgG based structures which comprise monoclonal antibodies, or fragments linked to one or more domain antibodies, and to methods of making such constructs and uses thereof, particularly uses in therapy.

The invention also provides a polynucleotide sequence encoding a heavy chain of any of the antigen binding constructs described herein, and a polynucleotide encoding a light chain of any of the antigen binding constructs described herein. Such polynucleotides represent the coding sequence which corresponds to the equivalent polypeptide sequences, however it will be understood that such polynucleotide sequences could be cloned into an expression vector along with a start codon, an appropriate signal sequence and a stop codon.
The invention also provides a recombinant transformed or transfected host cell comprising one or more polynucleotides encoding a heavy chain and a light chain of any of the antigen binding constructs described herein.

The invention further provides a method for the production of any of the antigen binding constructs described herein which method comprises the step of culturing a host cell comprising a first and second vector, said first vector comprising a polynucleotide encoding a heavy chain of any of the antigen binding constructs described herein and said second vector comprising a polynucleotide encoding a light chain of any of the antigen binding constructs described herein, in a serum-free culture media.

The invention further provides a pharmaceutical composition comprising an antigen binding construct as described herein a pharmaceutically acceptable carrier.

The invention also provides a domain antibody comprising or consisting of the polypeptide sequence set out in SEQ ID NO: 2 or SEQ ID NO: 3. In one aspect the invention provides a protein which is expressed from the polynucleotide sequence set out in SEQ ID NO: 60 or SEQ ID NO: 61.
Definitions

The term 'Protein Scaffold' as used herein includes but is not limited to an immunoglobulin (Ig) scaffold, for example an IgG scaffold, which may be a four chain or two chain antibody, or which may comprise only the Fc region of an antibody, or which may comprise one or more constant regions from an antibody, which constant regions may be of human or primate origin, or which may be an artificial chimera of human and primate constant regions. Such protein scaffolds may comprise antigen-binding sites in addition to the one or more constant regions, for example where the protein scaffold comprises a full IgG. Such protein scaffolds will be capable of being linked to other protein domains, for example protein domains which have antigen-binding sites, for example epitope-binding domains or ScFv domains.

A "domain" is a folded protein structure which has tertiary structure independent of the rest of the protein. Generally, domains are responsible for discrete functional properties of proteins and in many cases may be added, removed or transferred to other proteins without loss of function of the remainder of the protein and/or of the domain. A "single antibody variable domain" is a folded polypeptide domain comprising sequences characteristic of antibody variable domains. It therefore includes complete antibody variable domains and modified variable domains, for example, in which one or more loops have been replaced by sequences which are not characteristic of antibody variable domains, or antibody variable domains which have been truncated or comprise N- or C-terminal extensions, as well as folded fragments of variable domains which retain at least the binding activity and specificity of the full-length domain.

The phrase "immunoglobulin single variable domain" refers to an antibody variable domain \( \{V_H, V_{\text{HH}}, V_J\} \) that specifically binds an antigen or epitope independently of a different V region or domain. An immunoglobulin single variable domain can be present in a format (e.g., homo- or hetero-multimer) with other, different variable regions or variable domains where the other regions or domains are not required for antigen binding by the single immunoglobulin variable domain (i.e., where the immunoglobulin single variable domain binds antigen independently of the additional variable domains). A "domain antibody" or "dAb" is the same as an "immunoglobulin single variable domain" which is capable of binding to an antigen as the term is used herein. An immunoglobulin single variable domain may be a human antibody variable domain, but also includes single antibody variable domains from other species such as rodent (for example, as disclosed in WO 00/29004), nurse shark and Camelid \( V_{\text{HH}} \) dAbs. Camelid \( V_{\text{HH}} \) are immunoglobulin single variable domain polypeptides that are derived from species including camel, llama, alpaca, dromedary, and guanaco, which produce heavy chain antibodies naturally devoid of light chains. Such \( V_{\text{HH}} \) domains may be humanised according to standard techniques available in the art, and such domains are still considered to be "domain antibodies"
according to the invention. As used herein "VH" includes camelid VH domains. NARV are another type of immunoglobulin single variable domain which were identified in cartilaginous fish including the nurse shark. These domains are also known as Novel Antigen Receptor variable region (commonly abbreviated to V(NAR) or NARV). For further details see Mol. Immunol. 44, 656-665 (2006) and US20050043519A.

The term E pitope-binding domain" refers to a domain that specifically binds an antigen or epitope independently of a different V region or domain, this may be a domain antibody (dAb), for example a human, camelid or shark immunoglobulin single variable domain or it may be a domain which is a derivative of a scaffold selected from the group consisting of CTLA-4 (Evibody); lipocalin; Protein A derived molecules such as Z-domain of Protein A (Affibody, SpA), A-domain (Avimer/Maxibody); Heat shock proteins such as GroEl and GroES; transferrin (transbody); ankyrin repeat protein (DARPin); peptide aptamer; C-type lectin domain (Tetranectin); human γ-cryotillin and human ubiquitin (affilins); PDZ domains; scorpion toxinkunitz type domains of human protease inhibitors; and fibronectin (adnectin); which has been subjected to protein engineering in order to obtain binding to a ligand other than the natural ligand.

CTLA-4 (Cytotoxic T Lymphocyte-associated Antigen 4) is a CD28-family receptor expressed on mainly CD4+ T-cells. Its extracellular domain has a variable domain-like Ig fold. Loops corresponding to CDRs of antibodies can be substituted with heterologous sequence to confer different binding properties. CTLA-4 molecules engineered to have different binding specificities are also known as Evibodies. For further details see Journal of Immunological Methods 248 (1-2), 31-45 (2001)

Lipocalins are a family of extracellular proteins which transport small hydrophobic molecules such as steroids, bilins, retinoids and lipids. They have a rigid β-sheet secondary structure with a number of loops at the open end of the conical structure which can be engineered to bind to different target antigens. Anticalins are between 160-180 amino acids in size, and are derived from lipocalins. For further details see Biochim Biophys Acta 1482: 337-350 (2000), US7250297B1 and US20070224633

An affibody is a scaffold derived from Protein A of Staphylococcus aureus which can be engineered to bind to antigen. The domain consists of a three-helical bundle of approximately 58 amino acids. Libraries have been generated by randomisation of surface residues. For further details see Protein Eng. Des. Sel. 17, 455-462 (2004) and EP1641818A1
Avimers are multidomain proteins derived from the A-domain scaffold family. The native domains of approximately 35 amino acids adopt a defined disulphide bonded structure. Diversity is generated by shuffling of the natural variation exhibited by the family of A-domains. For further details see Nature Biotechnology 23(12), 1556 - 1561 (2005) and Expert Opinion on Investigational Drugs 16(6), 909-917 (June 2007).

A transferrin is a monomeric serum transport glycoprotein. Transferrins can be engineered to bind different target antigens by insertion of peptide sequences in a permissive surface loop. Examples of engineered transferrin scaffolds include the Trans-body. For further details see J. Biol. Chem 274, 24066-24073 (1999).

Designed Ankyrin Repeat Proteins (DARPins) are derived from Ankyrin which is a family of proteins that mediate attachment of integral membrane proteins to the cytoskeleton. A single ankyrin repeat is a 33 residue motif consisting of two α-helices and a β-turn. They can be engineered to bind different target antigens by randomising residues in the first α-helix and a β-turn of each repeat. Their binding interface can be increased by increasing the number of modules (a method of affinity maturation). For further details see J. Mol. Biol. 332, 489-503 (2003), PNAS 100(4), 1700-1705 (2003) and J. Mol. Biol. 369, 1015-1028 (2007) and US20040132028A1.

Fibronectin is a scaffold which can be engineered to bind to antigen. Adnectins consists of a backbone of the natural amino acid sequence of the 10th domain of the 15 repeating units of human fibronectin type III (FN3). Three loops at one end of the β-sandwich can be engineered to enable an Adnectin to specifically recognize a therapeutic target of interest. For further details see Protein Eng. Des. Sel. 18, 435-444 (2005), US20080139791, WO2005056764 and US6818418B1.

Peptide aptamers are combinatorial recognition molecules that consist of a constant scaffold protein, typically thioredoxin (TrxA) which contains a constrained variable peptide loop inserted at the active site. For further details see Expert Opin. Biol. Ther. 5, 783-797 (2005).

Microbodies are derived from naturally occurring microproteins of 25-50 amino acids in length which contain 3-4 cysteine bridges - examples of microproteins include KalataB1 and conotoxin and knottins. The microproteins have a loop which can be
engineered to include up to 25 amino acids without affecting the overall fold of the microprotein. For further details of engineered knottin domains, see WO2008098796.

Other epitope binding domains include proteins which have been used as a scaffold to engineer different target antigen binding properties include human γ-crystallin and human ubiquitin (affilins), kunitz type domains of human protease inhibitors, PDZ-domains of the Ras-binding protein AF-6, scorpion toxins (charybdotoxin), C-type lectin domain (tetraneectins) are reviewed in Chapter 7 - Non-Antibody Scaffolds from Handbook of Therapeutic Antibodies (2007, edited by Stefan Dubel) and Protein Science 15:14-27 (2006). Epitope binding domains of the present invention could be derived from any of these alternative protein domains.

As used herein, the terms "paired VH domain", "paired VL domain", and "paired VH/VL domains" refer to antibody variable domains which specifically bind antigen only when paired with their partner variable domain. There is always one VH and one VL in any pairing, and the term "paired VH domain" refers to the VH partner, the term "paired VL domain" refers to the VL partner, and the term "paired VH/VL domains" refers to the two domains together.

In one embodiment of the invention the antigen binding site binds to antigen with a Kd of at least 1mM, for example a Kd of 10nM, 1nM, 500pM, 200pM, 100pM, to each antigen as measured by Biacore™, such as the Biacore™ method as described in method 4 or 5.

As used herein, the term "antigen binding site" refers to a site on a construct which is capable of specifically binding to antigen, this may be a single domain, for example an epitope-binding domain, or it may be paired VH/VL domains as can be found on a standard antibody. In some aspects of the invention single-chain Fv (ScFv) domains can provide antigen-binding sites.

The terms "mAb/dAb" and dAb/mAb" are used herein to refer to antigen-binding constructs of the present invention. The two terms can be used interchangeably, and are intended to have the same meaning as used herein.

The term "constant heavy chain 1" is used herein to refer to the CH1 domain of an immunoglobulin heavy chain.

The term "constant light chain" is used herein to refer to the constant domain of an immunoglobulin light chain.
Detailed description of Invention

The present invention relates to an antigen-binding construct comprising a protein scaffold which is linked to one or more epitope-binding domains wherein the antigen-binding construct has at least two antigen binding sites at least one of which is from an epitope binding domain and at least one of which is from a paired VH/VL domain.

Such antigen-binding constructs comprise a protein scaffold, for example an Ig scaffold such as IgG, for example a monoclonal antibody, which is linked to one or more epitope-binding domains, for example a domain antibody, wherein the binding construct has at least two antigen binding sites, at least one of which is from an epitope binding domain, and to methods of producing and uses thereof, particularly uses in therapy.

Some examples of antigen-binding constructs according to the invention are set out in Figure 1.

The antigen-binding constructs of the present invention are also referred to as mAbdAbs.

In one embodiment the protein scaffold of the antigen-binding construct of the present invention is an Ig scaffold, for example an IgG scaffold or IgA scaffold. The IgG scaffold may comprise all the domains of an antibody (i.e. CH1, CH2, CH3, VH, VL). The antigen-binding construct of the present invention may comprise an IgG scaffold selected from IgG1, IgG2, IgG3, IgG4 or IgG4PE.

The antigen-binding construct of the present invention has at least two antigen binding sites, for example it has two binding sites, for example where the first binding site has specificity for a first epitope on an antigen and the second binding site has specificity for a second epitope on the same antigen. In a further embodiment there are 4 antigen binding sites, or 6 antigen binding sites, or 8 antigen binding sites, or 10 or more antigen-binding sites. In one embodiment the antigen binding construct has specificity for more than one antigen, for example two antigens, or for three antigens, or for four antigens.

In another aspect the invention relates to an antigen-binding construct comprising at least one homodimer comprising two or more structures of formula 1:
wherein

\[ X \text{ represents a constant antibody region comprising constant heavy domain 2 and constant heavy domain 3; } \]

\[ R_1, R_4, R_7 \text{ and } R_8 \text{ represent a domain independently selected from an epitope-binding domain; } \]

\[ R_2 \text{ represents a domain selected from the group consisting of constant heavy chain 1, and an epitope-binding domain; } \]

\[ R_3 \text{ represents a domain selected from the group consisting of a paired } VH \text{ and an epitope-binding domain; } \]

\[ R_5 \text{ represents a domain selected from the group consisting of constant light chain, and an epitope-binding domain; } \]

\[ R_6 \text{ represents a domain selected from the group consisting of a paired } VL \text{ and an epitope-binding domain; } \]

\[ n \text{ represents an integer independently selected from: } 0, 1, 2, 3 \text{ and } 4; \]

\[ m \text{ represents an integer independently selected from: } 0 \text{ and } 1, \]

wherein the Constant Heavy chain 1 and the Constant Light chain domains are associated;

wherein at least one epitope binding domain is present;

and when \( R_3 \) represents a paired \( VH \) domain, \( R_6 \) represents a paired \( VL \) domain, so that the two domains are together capable of binding antigen.
In one embodiment R^6\ represents a paired VL and R^3\ represents a paired VH.

In a further embodiment either one or both of R^7\ and R^8\ represent an epitope binding domain.

In yet a further embodiment either one or both of R^1\ and R^4\ represent an epitope binding domain.

In one embodiment R^4\ is present.

In one embodiment R^1\ R^7\ and R^8\ represent an epitope binding domain.

In one embodiment R^1\ R^7\ and R^8\ and R^4\ represent an epitope binding domain.

In one embodiment \((R^1)^m, (R^2)^m, (R^4)^m\) and \((R^5)^m\) = 0, i.e. are not present, R^3\ is a paired VH domain, R^6\ is a paired VL domain, R^8\ is a VH dAb, and R^7\ is a VL dAb.

In another embodiment \((R^1)^m, (R^2)^m, (R^4)^m\) and \((R^5)^m\) are 0, i.e. are not present, R^3\ is a paired VH domain, R^6\ is a paired VL domain, R^8\ is a VH dAb, and \((R^7)^m\) = 0 i.e. not present.

In another embodiment \((R^2)^m, (R^5)^m\) are 0, i.e. are not present, R^1\ is a dAb, R^4\ is a dAb, R^3\ is a paired VH domain, R^6\ is a paired VL domain, \((R^8)^m\) and \((R^7)^m\) = 0 i.e. not present.

In one embodiment of the present invention the epitope binding domain is a dAb.

It will be understood that any of the antigen-binding constructs described herein will be capable of neutralising one or more antigens.

The term "neutralises" and grammatical variations thereof as used throughout the present specification in relation to antigen binding constructs of the invention means that a biological activity of the target is reduced, either totally or partially, in the presence of the antigen binding constructs of the present invention in comparison to the activity of the target in the absence of such antigen binding constructs. Neutralisation may be due to but not limited to one or more of blocking ligand binding, preventing the ligand activating the receptor, down regulating the receptor or affecting effector functionality.

Levels of neutralisation can be measured in several ways, for example by use of any of the assays as set out in the examples and methods below, for example in an assay which measures inhibition of ligand binding to receptor which may be carried
out for example as described in any one of Methods 12, 19 or 21 or Example 32. The neutralisation of VEGF, IL-4, IL-13 or HGF in these assays is measured by assessing the decreased binding between the ligand and its receptor in the presence of neutralising antigen binding construct.

Levels of neutralisation can also be measured, for example in a TF1 assay which may be carried out for example as described in Method 8, 9, 10, 20 or 21. The neutralisation of IL-13, IL-4 or both of these cytokines in this assay is measured by assessing the inhibition of TF1 cell proliferation in the presence of neutralising antigen binding construct. Alternatively neutralisation could be measured in an EGFR phosphorylation assay which may be carried out for example as described in Method 13. The neutralisation of EGFR in this assay is measured by assessing the inhibition of tyrosine kinase phosphorylation of the receptor in the presence of neutralising antigen binding construct. Or, neutralisation could be measured in an IL-8 secretion assay in MRC-5 cells which may be carried out for example as described in Method 14 or 15. The neutralisation of TNFα or IL-1 R1 in this assay is measured by assessing the inhibition of IL-8 secretion in the presence of neutralising antigen binding construct.

Other methods of assessing neutralisation, for example, by assessing the decreased binding between the ligand and its receptor in the presence of neutralising antigen binding construct are known in the art, and include, for example, Biacore™ assays.

In an alternative aspect of the present invention there is provided antigen binding constructs which have at least substantially equivalent neutralising activity to the antibodies exemplified herein, for example antigen binding constructs which retain the neutralising activity of 586H-TVAAPS-210, or PascoH-G4S-474, or PascoH-474, PascoH-474 GS removed, Pascol-G4S-474 or PascolH-G4S-474 in the TF1 cell proliferation assay, or inhibition of pSTAT3 signalling assay as set out in Examples 4 and 20 respectively, or for example antigen binding constructs which retain the neutralising activity of BPC1603, BPC1604, BPC1605, BPC1606 in the VEGFR binding assay or inhibition of IGF-1 R receptor phosphorylation as set out in Examples 14.6 and 14.7.

The antigen binding constructs of the invention include those which have specificity for IL-13, for example which comprise an epitope-binding domain which is capable of binding to IL-13, or which comprise a paired VHA/L which binds to IL-13. The antigen binding construct may comprise an antibody which is capable of binding to IL-13. The antigen binding construct may comprise a dAb which is capable of binding to IL-13.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens selected from IL-13, IL-5, and IL-4, for example where it is capable
of binding IL-13 and IL-4, or where it is capable of binding IL-13 and IL-5, or where it is capable of binding IL-5 and IL-4.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens selected from IL-13, IL-5, and IL-4, for example where it is capable of binding IL-13 and IL-4 simultaneously, or where it is capable of binding IL-13 and IL-5 simultaneously, or where it is capable of binding IL-5 and IL-4 simultaneously.

It will be understood that any of the antigen-binding constructs described herein may be capable of binding two or more antigens simultaneously, for example, as determined by stochiometry analysis by using a suitable assay such as that described in the Examples section, method 7.

Examples of antigen-binding constructs of the invention include IL-13 antibodies which have an epitope binding domain with a specificity for IL-4, for example an anti-IL-4 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO:16 to 39, SEQ ID NO:41 to 43, SEQ ID NO:87 to 90, SEQ ID NO:151, SEQ ID NO:152 or SEQ ID NO:155. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Examples of such antigen-binding constructs include IL-4 antibodies which have an epitope binding domain with a specificity for IL-13, for example an anti-IL-13 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO:48 to 53, SEQ ID NO:91, SEQ ID NO:92, SEQ ID NO:149, SEQ ID NO:150, or SEQ ID NO:157 to 160, and/or the light chain sequence set out in SEQ ID NO:54 to 59.

Antigen binding constructs of the present invention include IL-4 antibodies with an IL-13 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-13 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-13 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-13 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.
binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-13 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Examples of such antigen-binding constructs include IL-13 antibodies which have an epitope binding domain with a specificity for IL-5, for example an anti-IL-5 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-5 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-5 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL-13 antibodies with an IL-5 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Examples of such antigen-binding constructs include IL-5 antibodies which have an epitope binding domain with a specificity for IL-13, for example an anti-IL-13 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the light chain sequence set out in SEQ ID NO: 72.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-13 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-13 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-13 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-13 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.
Examples of such antigen-binding constructs include IL-4 antibodies which have an epitope binding domain with a specificity for IL-5, for example an anti-IL-5 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-5 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-5 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-5 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-4 antibodies with an IL-5 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Examples of such antigen-binding constructs include IL-5 antibodies which have an epitope binding domain with a specificity for IL-4, for example an anti-IL-4 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 71.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The invention also provides a trispecific binding construct which is capable of binding to IL-4, IL-13 and IL-5.

Examples of such antigen-binding constructs include IL-5 antibodies which have an epitope binding domain with a specificity for IL-4, for example an anti-IL-4 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain and an epitope binding domain with a specificity for IL-13, for example an anti-IL-13 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain.
Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the light chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the light chain and an IL-13 epitope binding domain attached to the c-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-5 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.
The antigen binding constructs of the invention include those which have specificity for IL-18, for example which comprises an epitope-binding domain which is capable of binding to IL-18, or which comprises a paired VH/VL which binds to IL-18.

The antigen binding construct may comprise an antibody which is capable of binding to IL-18. The antigen binding construct may comprise a dAb which is capable of binding to IL-18.

The invention also provides a trispecific binding construct which is capable of binding to IL-4, IL-13 and IL-18.

Examples of such antigen-binding constructs include IL-18 antibodies which have an epitope binding domain with a specificity for IL-4, for example an anti-IL-4 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain and an epitope binding domain with a specificity for IL-13, for example an anti-IL-13 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the light chain and an IL-13 epitope binding domain attached to the n-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the n-terminus of the light chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the c-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the heavy chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.
Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the n-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the c-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the n-terminus of the heavy chain.

Antigen binding constructs of the present invention include IL-18 antibodies with an IL-4 epitope binding domain attached to the c-terminus of the light chain and an IL-13 epitope binding domain attached to the n-terminus of the light chain.

Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for TNFα, for example which comprises an epitope-binding domain which is capable of binding to TNFα, or which comprises a paired VH/VL which binds to TNFα. The antigen binding construct may comprise an antibody which is capable of binding to TNFα. The antigen binding construct may comprise a dAb which is capable of binding to TNFα.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens selected from TNFα, EGFR and VEGF, for example where it is capable of binding TNFα and EGFR, or where it is capable of binding TNFα and VEGF, or where it is capable of binding EGFR and VEGF. Examples of such antigen-binding constructs include TNFα antibodies which have an epitope binding domain with a specificity for EGFR, for example an anti-EGFR dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example a mAbdAb having the heavy chain sequence set out in SEQ ID NO: 74, and/or the light chain sequence set out in SEQ ID NO: 79.

Antigen binding constructs of the present invention include TNFα antibodies with an EGFR epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include TNFα antibodies with an EGFR epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include TNFα antibodies with an EGFR epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include TNFα antibodies with an EGFR epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding
constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Antigen binding constructs of the present invention include EGFR antibodies with an TNFα epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include EGFR antibodies with an TNFα epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include EGFR antibodies with an TNFα epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include EGFR antibodies with an TNFα epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Examples of such antigen-binding constructs include TNFα antibodies which have an epitope binding domain with a specificity for VEGF, for example an anti-VEGF dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example a mAbdAb having the heavy chain sequence set out in SEQ ID NO: 75, 78 or 185.

The antigen-binding construct of the present invention may have specificity for more than one antigen, for example where it is capable of binding TNFα, and one or both antigens selected from IL-4 and IL-13, for example where it is capable of binding TNFα and IL-4, or where it is capable of binding TNFα and IL-13, or where it is capable of binding TNFα and IL-13 and IL-4. Examples of such antigen-binding constructs include IL-13 antibodies which have an epitope binding domain with a specificity for TNFα, for example an anti-TNFα adnectin, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example a mAbdAb having the heavy chain sequence set out in SEQ ID NO: 134 or 135. Other examples of such antigen-binding constructs include IL-4 antibodies which have an epitope binding domain with a specificity for TNFα, for example an anti-TNFα adnectin, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example a mAbdAb having the heavy chain sequence set out in SEQ ID NO: 146 or 147.

Antigen binding constructs of the present invention include TNFα antibodies with an VEGF epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include TNFα antibodies with an VEGF epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include TNFα antibodies with an VEGF epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding
constructs of the present invention include TNFα antibodies with an VEGF epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Antigen binding constructs of the present invention include VEGF antibodies with an TNFα epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include VEGF antibodies with an TNFα epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include VEGF antibodies with an TNFα epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include VEGF antibodies with an TNFα epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for CD-20, for example which comprises an epitope-binding domain which is capable of binding to CD-20, or which comprises a paired VH/VL which binds to CD-20. The antigen binding construct may comprise an antibody which is capable of binding to CD-20, for example it may comprise an antibody having the heavy and light chain sequences of SEQ ID NO: 120 and 117. The antigen binding construct may comprise a dAb which is capable of binding to CD-20. Examples of mAbdAbs with specificity for CD-20 are those having the heavy chain sequence set out in SEQ ID NO: 116, 118 or those having the light chain sequence set out in SEQ ID NO: 119 or 121. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for IL1 R1, for example which comprise an epitope-binding domain which is capable of binding to IL1 R1, or which comprises a paired VH/VL which binds to IL1 R1. The antigen binding construct may comprise an antibody which is capable of binding to IL1 R1. The antigen binding construct may comprise a dAb which is capable of binding to IL1 R1.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding IL1 R1 and a second antigen, for example where it is capable of binding IL1 R1 and VEGF. Examples of such antigen-binding constructs include IL1 R1 antibodies which have an epitope binding domain with a specificity for VEGF, for example an anti-
VEGF dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example a mAbdAb having the light chain sequence set out in SEQ ID NO: 77.

Antigen binding constructs of the present invention include IL1R1 antibodies with an VEGF epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include IL1R1 antibodies with an VEGF epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include IL1R1 antibodies with an VEGF epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include IL1R1 antibodies with an VEGF epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

Antigen binding constructs of the present invention include VEGF antibodies with an IL1R1 epitope binding domain attached to the n-terminus of the heavy chain. Antigen binding constructs of the present invention include VEGF antibodies with an IL1R1 epitope binding domain attached to the n-terminus of the light chain. Antigen binding constructs of the present invention include VEGF antibodies with an IL1R1 epitope binding domain attached to the c-terminus of the heavy chain. Antigen binding constructs of the present invention include VEGF antibodies with an IL1R1 epitope binding domain attached to the c-terminus of the light chain. Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for EGFR, for example which comprises an epitope-binding domain which is capable of binding to EGFR, or which comprises a paired VH/VL which binds to EGFR. The antigen binding construct may comprise an antibody which is capable of binding to EGFR. The antigen binding construct may comprise a dAb which is capable of binding to EGFR. Some examples of such antigen binding construct will be capable of binding to an epitope on EGFR comprising SEQ ID NO:103, for example an antigen binding construct comprising one or more of the CDRs set out in SEQ ID NO: 97 to SEQ ID NO: 102 and SEQ ID NO: 104 to SEQ ID NO: 107.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens selected from EGFR, IGF-1R, VEGFR2 and VEGF, for example where it is capable of binding EGFR and IGF-1 R, or where it is capable of binding EGFR and VEGF, or where it is capable of binding VEGF and IGF-1 R, or where it is
capable of binding EGFR and VEGFR2, or where it is capable of binding IGF-1 R and VEGFR2, or where it is capable of binding VEGF and VEGFR2, or where it is capable of binding EGFR, IGF-1 R and VEGFR2, or where it is capable of binding VEGF, IGF-1 R and VEGFR2, or where it is capable of binding EGFR, VEGF and VEGFR2, or where it is capable of binding EGFR, VEGF and IGF1 R. Examples of such antigen-binding constructs include EGFR antibodies which have an epitope binding domain with a specificity for VEGFR2, for example an anti-VEGFR2 adnectin, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 136, 140 or 144 and/or the light chain sequence set out in SEQ ID NO: 138, 142 or 145.

Examples of such antigen-binding constructs include EGFR antibodies which have an epitope binding domain with a specificity for VEGF, for example an anti-VEGF dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 165, 174, 176, 178, 184 or 186 and/or the light chain sequence set out in SEQ ID NO: 188 or 190.

Examples of such antigen-binding constructs include VEGF antibodies which have an epitope binding domain with a specificity for EGFR, for example an anti-EGFR dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 180. Such mAbdAbs may also comprise the light chain sequence set out in SEQ ID NO: 182.

Examples of such antigen-binding constructs include IGF-1 R antibodies which have an epitope binding domain with a specificity for VEGF, for example an anti-VEGF lipocalin, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 123 or 125. Such mAbdAbs may also comprise the light chain sequence set out in SEQ ID NO: 113.

Examples of such antigen-binding constructs include IGF-1 R antibodies which have an epitope binding domain with a specificity for VEGFR2, for example an anti-VEGFR2 adnectin, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain, for example the mAbdAb having the heavy chain sequence set out in SEQ ID NO: 124 or 133. Such mAbdAbs may also comprise the light chain sequence set out in SEQ ID NO: 113.

The antigen binding constructs of the invention include those which have specificity for IL-23, for example which comprises an epitope-binding domain which is capable of binding to IL-23, or which comprises a paired VH/VL which binds to IL-23.

The antigen binding construct may comprise an antibody which is capable of binding to IL-23. The antigen binding construct may comprise a dAb which is capable of binding to IL-23.
In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens selected from TH17 type cytokines, for example. IL-17, IL-22, or IL-21, for example where it is capable of binding IL-23 and IL-17, or where it is capable of binding IL-23 and IL-21, or where it is capable of binding IL-23 and IL-22.

Examples of such antigen-binding constructs include IL-23 antibodies which have an epitope binding domain with a specificity for IL-17, for example an anti-IL-17 dAb, attached to the c-terminus or the n-terminus of the heavy chain or the c-terminus or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for PDGFRα, for example which comprises an epitope-binding domain which is capable of binding to PDGFRα, or which comprises a paired VH/VL which binds to PDGFRα. The antigen binding construct may comprise an antibody which is capable of binding to PDGFRα. The antigen binding construct may comprise a dAb which is capable of binding to PDGFRα.

The antigen binding constructs of the invention include those which have specificity for FGFR1, for example which comprises an epitope-binding domain which is capable of binding to FGFR1, or which comprises a paired VH/VL which binds to FGFR1. The antigen binding construct may comprise an antibody which is capable of binding to FGFR1. The antigen binding construct may comprise a dAb which is capable of binding to FGFR1.

The antigen binding constructs of the invention include those which have specificity for FGFR3, for example which comprises an epitope-binding domain which is capable of binding to FGFR3, or which comprises a paired VH/VL which binds to FGFR3. The antigen binding construct may comprise an antibody which is capable of binding to FGFR3. The antigen binding construct may comprise a dAb which is capable of binding to FGFR3.

The antigen binding constructs of the invention include those which have specificity for VEGFR2, for example which comprises an epitope-binding domain which is capable of binding to VEGFR2, or which comprises a paired VH/VL which binds to VEGFR2. The antigen binding construct may comprise an antibody which is capable of binding to VEGFR2. The antigen binding construct may comprise a dAb which is capable of binding to VEGFR2.

The antigen binding constructs of the invention include those which have specificity for VEGFR3, for example which comprises an epitope-binding domain which is capable of binding to VEGFR3, or which comprises a paired VH/VL which binds to VEGFR3.

The antigen binding construct may comprise an antibody which is capable of binding to VEGFR3. The antigen binding construct may comprise a dAb which is capable of binding to VEGFR3.
The antigen binding constructs of the invention include those which have specificity for VE cadherin, for example which comprises an epitope-binding domain which is capable of binding to VE cadherin, or which comprises a paired VH/VL which binds to VE cadherin.

The antigen binding construct may comprise an antibody which is capable of binding to VE cadherin. The antigen binding construct may comprise a dAb which is capable of binding to VE cadherin.

The antigen binding constructs of the invention include those which have specificity for neuropilin, for example which comprises an epitope-binding domain which is capable of binding to neuropilin, or which comprises a paired VH/VL which binds to neuropilin.

The antigen binding construct may comprise an antibody which is capable of binding to neuropilin. The antigen binding construct may comprise a dAb which is capable of binding to neuropilin.

The antigen binding constructs of the invention include those which have specificity for Flt-3, for example which comprises an epitope-binding domain which is capable of binding to Flt-3, or which comprises a paired VH/VL which binds to Flt-3.

The antigen binding construct may comprise an antibody which is capable of binding to Flt-3. The antigen binding construct may comprise a dAb which is capable of binding to Flt-3.

The antigen binding constructs of the invention include those which have specificity for ron, for example which comprises an epitope-binding domain which is capable of binding ron, or which comprises a paired VH/VL which binds to ron.

The antigen binding construct may comprise an antibody which is capable of binding to ron. The antigen binding construct may comprise a dAb which is capable of binding to ron.

The antigen binding constructs of the invention include those which have specificity for Trp-1, for example which comprises an epitope-binding domain which is capable of binding Trp-1, or which comprises a paired VH/VL which binds to Trp-1.

The antigen binding construct may comprise an antibody which is capable of binding to Trp-1. The antigen binding construct may comprise a dAb which is capable of binding to Trp-1.

In one embodiment the antigen-binding construct of the present invention has specificity for more than one antigen, for example where it is capable of binding two or more antigens which are implicated in cancer, for example where it is capable of binding two or more antigens selected from PDGFRα, FGFR1, FGFR3, VEGFR2, VEGFR3, IGF1 R, EGFR and VEGF, VE cadherin, neuropilin, Flt-3, ron, Trp-1, CD-20 for example where it is capable of binding PDGFRα and FGFR1, or where it is capable of binding PDGFRα and VEGFR, or where it is capable of binding PDGFRα and FGFR3, or where it is capable of binding PDGFRα and VEGFR2, or where it is capable of binding PDGFRα and VEGFR3, or where it is capable of binding PDGFRα and IGF1 R, or where it is capable of binding PDGFRα and EGFR, or where it is
capable of binding PDGFRα and VEGF, or where it is capable of binding PDGFRα and VE cadherin, or where it is capable of binding PDGFRα and neuropilin, or where it is capable of binding PDGFRα and Flt-3, or where it is capable of binding PDGFRα and Ron, or where it is capable of binding PDGFRα and Trp1, or where it is capable of binding PDGFRα and CD-20, or where it is capable of binding FGFR1 and FGFR3, or where it is capable of binding FGFR1 and VEGF, or where it is capable of binding FGFR1 and VEGFR2, or where it is capable of binding FGFR1 and VEGFR3, or where it is capable of binding FGFR1 and IGF1 R, or where it is capable of binding FGFR1 and EGFR, or where it is capable of binding FGFR1 and VEGFR, or where it is capable of binding FGFR1 and VEGF, or where it is capable of binding FGFR1 and VE cadherin, or where it is capable of binding FGFR1 and neuropilin, or where it is capable of binding FGFR1 and Flt-3, or where it is capable of binding FGFR1 and Ron, or where it is capable of binding FGFR1 and Trp-1, or where it is capable of binding FGFR1 and CD-20, or where it is capable of binding FGFR3 and VEGFR2, or where it is capable of binding FGFR3 and IGF1 R, or where it is capable of binding FGFR3 and neuropilin, or where it is capable of binding FGFR3 and Flt-3, or where it is capable of binding FGFR3 and Ron, or where it is capable of binding FGFR3 and Trp-1, or where it is capable of binding FGFR3 and CD-20, or where it is capable of binding VEGFR2 and VEGFR3, or where it is capable of binding VEGFR2 and IGF1 R, or where it is capable of binding VEGFR2 and EGFR, or where it is capable of binding VEGFR2 and VEGF, or where it is capable of binding VEGFR2 and VEGF2 and neuropilin, or where it is capable of binding VEGFR2 and Ron, or where it is capable of binding VEGFR2 and Trp-1, or where it is capable of binding VEGFR2 and CD-20, or where it is capable of binding VEGFR3 and IGF-1 R, or where it is capable of binding VEGFR3 and EGFR, or where it is capable of binding VEGFR3 and VEGF, or where it is capable of binding VEGFR3 and Neuropilin, or where it is capable of binding VEGFR3 and Flt-3, or where it is capable of binding VEGFR3 and CD-20, or where it is capable of binding IGF1 R and EGFR, or where it is capable of binding IGF1 R and VEGF, or where it is capable of binding IGF1 R and VE cadherin, or where it is capable of binding IGF1 R and neuropilin, or where it is capable of binding IGF1 R and Flt-3, or where it is capable of binding EGFR and Ron, or where it is capable of binding EGFR and Trp-1, or where it is capable of binding EGFR and CD-20, or where it is capable of binding VEGF and VEGF2 and neuropilin, or where it is capable of binding VEGF and neuropilin, or where it is capable of binding VEGF and CD-20.
and ron, or where it is capable of binding VEGF and Trp-1, or where it is capable of binding VEGF and CD-20, or where it is capable of binding VE cadherin and neuropilin, or where it is capable of binding VE cadherin and Flt-3, or where it is capable of binding VE cadherin and ron, or where it is capable of binding VE cadherin and Trp-1, or where it is capable of binding VE cadherin and CD-20, or where it is capable of binding neuropilin and Flt-3, or where it is capable of binding neuropilin and ron, or where it is capable of binding neuropilin and Trp-1, or where it is capable of binding neuropilin and CD-20, or where it is capable of binding Flt-3 and ron, or where it is capable of binding Flt-3 and Trp-1, or where it is capable of binding Flt-3 and CD-20, or where it is capable of binding ron and Trp-1, or where it is capable of binding ron and CD-20, and or where it is capable of binding Trp-1 and CD-20.

Such antigen-binding constructs may also have one or more further epitope binding domains with the same or different antigen-specificity attached to the c-terminus and/or the n-terminus of the heavy chain and/or the c-terminus and/or n-terminus of the light chain.

The antigen binding constructs of the invention include those which have specificity for beta-amyloid, for example which comprise an epitope-binding domain which is capable of binding to beta-amyloid, or which comprises a paired VH/VL which binds to beta-amyloid.

The antigen binding construct may comprise an antibody which is capable of binding to beta-amyloid. The antigen binding construct may comprise a dAb which is capable of binding to beta-amyloid.

The antigen binding constructs of the invention include those which have specificity for CD-3, for example which comprise an epitope-binding domain which is capable of binding to CD-3, or which comprises a paired VH/VL which binds to CD-3.

The antigen binding construct may comprise an antibody which is capable of binding to CD-3. The antigen binding construct may comprise a dAb which is capable of binding to CD-3.

The antigen binding constructs of the invention include those which have specificity for gplllb/lla, for example which comprise an epitope-binding domain which is capable of binding to gplllb/lla, or which comprises a paired VH/VL which binds to gplllb/lla.

The antigen binding construct may comprise an antibody which is capable of binding to gplllb/lla. The antigen binding construct may comprise a dAb which is capable of binding to gplllb/lla.

The antigen binding constructs of the invention include those which have specificity for TGFbeta, for example which comprise an epitope-binding domain which is capable of binding to TGFbeta, or which comprises a paired VH/VL which binds to TGFbeta.

The antigen binding construct may comprise an antibody which is capable of binding to TGFbeta. The antigen binding construct may comprise a dAb which is capable of binding to TGFbeta.
In one embodiment of the present invention there is provided an antigen binding construct according to the invention described herein and comprising a constant region such that the antibody has reduced ADCC and/or complement activation or effector functionality. In one such embodiment the heavy chain constant region may comprise a naturally disabled constant region of IgG2 or IgG4 isotype or a mutated IgG1 constant region. Examples of suitable modifications are described in EP0307434. One example comprises the substitutions of alanine residues at positions 235 and 237 (EU index numbering).

In one embodiment the antigen-binding constructs of the present invention will retain Fc functionality for example will be capable of one or both of ADCC and CDC activity. Such antigen-binding constructs may comprise an epitope-binding domain located on the light chain, for example on the c-terminus of the light chain.

The invention also provides a method of maintaining ADCC and CDC function of antigen-binding constructs by positioning of the epitope binding domain on the light chain of the antibody in particular, by positioning the epitope binding domain on the c-terminus of the light chain. Such ADCC and CDC function can be measured by any suitable assay, for example the ADCC assay set out in Example 15.3 and the CDC assay set out in Example 15.4.

The invention also provides a method of reducing CDC function of antigen-binding constructs by positioning of the epitope binding domain on the heavy chain of the antibody, in particular, by positioning the epitope binding domain on the c-terminus of the heavy chain. Such CDC function can be measured by any suitable assay, for example the CDC assay set out in Example 15.4.

In a further embodiment the antigen-binding construct of the present invention is capable of binding two or more antigens selected from VEGF, IGF-1 R and EGFR, for example it is capable of binding EGFR and VEGF, or EGFR and IGF1 R, or IGF1 R and VEGF, or for example it is capable of binding to TNF and IL1-R. In embodiments of the invention which comprise an IGF-1 R binding site, the IGF-1 R binding site of the antigen-binding construct of the invention may comprise a paired VH/VL domain in the protein scaffold, which paired VH/VL domain may comprise one or more of the CDRs selected from those set out in SEQ ID NO: 80, SEQ ID NO: 81, SEQ ID NO: 82, SEQ ID NO: 83, SEQ ID NO: 84, SEQ ID NO: 85 and SEQ ID NO: 86, for example it may comprise at least CDRH3 as set out in SEQ ID NO:80, for example it may comprise all the CDRs set out in SEQ ID NO: 80, SEQ ID NO: 81, SEQ ID NO: 82, SEQ ID NO: 83, SEQ ID NO: 85, and SEQ ID NO: 86.

In embodiments of the invention which comprise an EGFR binding site, the antigen-binding construct of the present invention may bind to an epitope comprising
residues 273-501 of the mature or normal or wild type EGFR sequence, for example it may bind to an epitope comprising residues 287-302 of the mature or normal or wildtype EGFR (SEQ ID NO:103).

In one embodiment, the EGFR binding site of the antigen-binding construct of the invention may comprise a paired VH/VL domain in the protein scaffold, which paired VH/VL domain may comprise one or more of the CDRs selected from those set out in SEQ ID NO: 104, SEQ ID NO: 105, SEQ ID NO: 106, SEQ ID NO: 101, and SEQ ID NO: 102, for example, it may comprise CDRH3 as set out in SEQ ID NO: 106, or it may comprise all six CDRs set out in SEQ ID NO: 104, SEQ ID NO: 105, SEQ ID NO: 106, SEQ ID NO: 100, SEQ ID NO: 101, and SEQ ID NO: 102.

Such paired VH/VL domain may further comprise additional residues, particularly in the heavy chain CDRs, and in one embodiment, CDRH1 may comprise SEQ ID NO: 104 plus up to five additional residues, for example one or more of the five additional residues which are set out in SEQ ID NO: 97, CDRH2 may comprise SEQ ID NO: 105 plus up to two additional residues, for example one or both of the two additional residues which are set out in SEQ ID NO: 98 and SEQ ID NO: 107, and CDRH3 may comprise SEQ ID NO: 106 plus up to two additional residues, for example one or both of the two additional residues which are set out in SEQ ID NO: 99. In one such embodiment, the paired VH/VL comprises one or more of the CDRs set out in SEQ ID NO: 97, SEQ ID NO: 98, SEQ ID NO: 99, SEQ ID NO: 100, SEQ ID NO: 101, and SEQ ID NO: 102, for example it may comprise at least CDRH3 as set out in SEQ ID NO:99, for example it may comprise all six CDRs set out in SEQ ID NO: 97, SEQ ID NO: 98, SEQ ID NO: 99, SEQ ID NO: 100, SEQ ID NO: 101 and SEQ ID NO: 102.

(more detail of suitable antibodies can be found in WO02/092771 and WO2005/081854).

In one embodiment, the antigen binding constructs comprise an epitope-binding domain which is a domain antibody (dAb), for example the epitope binding domain may be a human VH or human VL, or a camelid V_{HH} or a shark dAb (NARV).

In one embodiment the antigen binding constructs comprise an epitope-binding domain which is a derivative of a scaffold selected from the group consisting of CTLA-4 (Evibody); lipocalin; Protein A derived molecules such as Z-domain of Protein A (Affibody, SpA), A-domain (Avimer/Maxibody); Heat shock proteins such as GroEl and GroES; transferrin (trans-body); ankyrin repeat protein (DARPin); peptide aptamer; C-type lectin domain (Tetranectin); human γ-crystallin and human ubiquitin (affilins); PDZ domains; scorpion toxinkunitz type domains of human protease inhibitors; and fibronectin (adnectin); which has been subjected to protein engineering in order to obtain binding to a ligand other than the natural ligand.

The antigen binding constructs of the present invention may comprise a protein scaffold attached to an epitope binding domain which is an adnectin, for example an IgG scaffold with an adnectin attached to the c-terminus of the heavy chain, or it may comprise a protein scaffold attached to an adnectin, for example an IgG scaffold with
an adnectin attached to the n-terminus of the heavy chain, or it may comprise a protein scaffold attached to an adnectin, for example an IgG scaffold with an adnectin attached to the c-terminus of the light chain, or it may comprise a protein scaffold attached to an adnectin, for example an IgG scaffold with an adnectin attached to the n-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is CTLA-4, for example an IgG scaffold with CTLA-4 attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with CTLA-4 attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with CTLA-4 attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with CTLA-4 attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a lipocalin, for example an IgG scaffold with a lipocalin attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a lipocalin attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a lipocalin attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a lipocalin attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is an SpA, for example an IgG scaffold with an SpA attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an SpA attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an SpA attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with an SpA attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is an affibody, for example an IgG scaffold with an affibody attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an affibody attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an affibody attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with an affibody attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is an affimer, for example an IgG scaffold with an affimer attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an affimer attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with an affimer attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with an affimer attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a GroEI, for example an IgG scaffold with a GroEI attached to the n-terminus of the heavy chain, or it may
comprise for example an IgG scaffold with a GroEI attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a GroEI attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a GroEI attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a transferrin, for example an IgG scaffold with a transferrin attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a transferrin attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a transferrin attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a transferrin attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a GroES, for example an IgG scaffold with a GroES attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a GroES attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a GroES attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a GroES attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a DARPin, for example an IgG scaffold with a DARPin attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a DARPin attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a DARPin attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a DARPin attached to the c-terminus of the light chain.

In other embodiments it may comprise a protein scaffold, for example an IgG scaffold, attached to an epitope binding domain which is a peptide aptamer, for example an IgG scaffold with a peptide aptamer attached to the n-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a peptide aptamer attached to the c-terminus of the heavy chain, or it may comprise for example an IgG scaffold with a peptide aptamer attached to the n-terminus of the light chain, or it may comprise an IgG scaffold with a peptide aptamer attached to the c-terminus of the light chain.

In one embodiment of the present invention there are four epitope binding domains, for example four domain antibodies, two of the epitope binding domains may have specificity for the same antigen, or all of the epitope binding domains present in the antigen-binding construct may have specificity for the same antigen.

Protein scaffolds of the present invention may be linked to epitope-binding domains by the use of linkers. Examples of suitable linkers include amino acid sequences which may be from 1 amino acid to 150 amino acids in length, or from 1 amino acid to 140 amino acids, for example, from 1 amino acid to 130 amino acids, or from 1 to
120 amino acids, or from 1 to 80 amino acids, or from 1 to 50 amino acids, or from 1 to 20 amino acids, or from 1 to 10 amino acids, or from 5 to 18 amino acids. Such sequences may have their own tertiary structure, for example, a linker of the present invention may comprise a single variable domain. The size of a linker in one embodiment is equivalent to a single variable domain. Suitable linkers may be of a size from 1 to 20 angstroms, for example less than 15 angstroms, or less than 10 angstroms, or less than 5 angstroms.

In one embodiment of the present invention at least one of the epitope binding domains is directly attached to the I\(_g\) scaffold with a linker comprising from 1 to 150 amino acids, for example 1 to 20 amino acids, for example 1 to 10 amino acids. Such linkers may be selected from any one of those set out in SEQ ID NO: 6 to 11, 'STG' (serine, threonine, glycine), 'GSTG' or 'RS', for example the linker may be TVAAPS', or the linker may be 'GGGGS'. Linkers of use in the antigen binding constructs of the present invention may comprise alone or in addition to other linkers, one or more sets of GS residues, for example 'GSTVAAPS' or TVAAPSGS' or 'GSTVAAPSGS'. In another embodiment there is no linker between the epitope binding domain, for example the dAb, and the I\(_g\) scaffold. In another embodiment the epitope binding domain, for example a dAb, is linked to the I\(_g\) scaffold by the linker TVAAPS'. In another embodiment the epitope binding domain, for example a dAb, is linked to the I\(_g\) scaffold by the linker 'GS'.

In one embodiment, the antigen-binding construct of the present invention comprises at least one epitope binding domain which is capable of binding human serum albumin.

In one embodiment, there are at least 3 antigen binding sites, for example there are 4, or 5 or 6 or 8 or 10 antigen binding sites and the antigen binding construct is capable of binding at least 3 or 4 or 5 or 6 or 8 or 10 antigens, for example it is capable of binding 3 or 4 or 5 or 6 or 8 or 10 antigens simultaneously.

The invention also provides the antigen-binding constructs for use in medicine, for example for use in the manufacture of a medicament for treating cancer or inflammatory diseases such as asthma, rheumatoid arthritis, or osteoarthritis.

The invention provides a method of treating a patient suffering from cancer or inflammatory diseases such as asthma, rheumatoid arthritis, or osteoarthritis, comprising administering a therapeutic amount of an antigen-binding construct of the invention.
The antigen-binding constructs of the invention may be used for the treatment of cancer or inflammatory diseases such as asthma, rheumatoid arthritis, or osteoarthritis.

The antigen-binding constructs of the invention may have some effector function. For example if the protein scaffold contains an Fc region derived from an antibody with effector function, for example if the protein scaffold comprises CH2 and CH3 from IgG1. Levels of effector function can be varied according to known techniques, for example by mutations in the CH2 domain, for example wherein the IgG1 CH2 domain has one or more mutations at positions selected from 239 and 332 and 330, for example the mutations are selected from S239D and I332E and A330L such that the antibody has enhanced effector function, and/or for example altering the glycosylation profile of the antigen-binding construct of the invention such that there is a reduction in fucosylation of the Fc region.

Protein scaffolds of use in the present invention include full monoclonal antibody scaffolds comprising all the domains of an antibody, or protein scaffolds of the present invention may comprise a non-conventional antibody structure, such as a monovalent antibody. Such monovalent antibodies may comprise a paired heavy and light chain wherein the hinge region of the heavy chain is modified so that the heavy chain does not homodimerise, such as the monovalent antibody described in WO2007059782. Other monovalent antibodies may comprise a paired heavy and light chain which dimerises with a second heavy chain which is lacking a functional variable region and CH1 region, wherein the first and second heavy chains are modified so that they will form heterodimers rather than homodimers, resulting in a monovalent antibody with two heavy chains and one light chain such as the monovalent antibody described in WO2006015371. Such monovalent antibodies can provide the protein scaffold of the present invention to which epitope binding domains can be linked, for example such as the antigen binding constructs describe in Example 32.

Epitope-binding domains of use in the present invention are domains that specifically bind an antigen or epitope independently of a different V region or domain, this may be a domain antibody or may be a domain which is a derivative of a scaffold selected from the group consisting of CTLA-4 (Evibody); lipocalin; Protein A derived molecules such as Z-domain of Protein A (Affibody, SpA), A-domain (Avimer/Maxibody); Heat shock proteins such as GroEL and GroES; transferrin (trans-body); ankyrin repeat protein (DARPin); peptide aptamer; C-type lectin domain (Tetranectin); human γ-crystallin and human ubiquitin (affilins); PDZ domains; scorpion toxikunitz type domains of human protease inhibitors; and fibronectin (adnectin); which has been subjected to protein engineering in order to obtain binding to a ligand other than the natural ligand. In one embodiment this may be an domain antibody or other suitable domains such as a domain selected from the group consisting of CTLA-4, lipocalin,
SpA, an Affibody, an avimer, GroEl, transferrin, GroES and fibronectin. In one embodiment this may be selected from a dAb, an Affibody, an ankyrin repeat protein (DARPn) and an adnectin. In another embodiment this may be selected from an Affibody, an ankyrin repeat protein (DARPn) and an adnectin. In another embodiment this may be a domain antibody, for example a domain antibody selected from a human, camelid or shark (NARV) domain antibody.

Epitope-binding domains can be linked to the protein scaffold at one or more positions. These positions include the C-terminus and the N-terminus of the protein scaffold, for example at the C-terminus of the heavy chain and/or the C-terminus of the light chain of an IgG, or for example the N-terminus of the heavy chain and/or the N-terminus of the light chain of an IgG.

In one embodiment, a first epitope binding domain is linked to the protein scaffold and a second epitope binding domain is linked to the first epitope binding domain, for example where the protein scaffold is an IgG scaffold, a first epitope binding domain may be linked to the C-terminus of the heavy chain of the IgG scaffold, and that epitope binding domain can be linked at its C-terminus to a second epitope binding domain, or for example a first epitope binding domain may be linked to the C-terminus of the light chain of the IgG scaffold, and that first epitope binding domain may be further linked at its C-terminus to a second epitope binding domain, or for example a first epitope binding domain may be linked to the N-terminus of the heavy chain of the IgG scaffold, and that first epitope binding domain may be further linked at its N-terminus to a second epitope binding domain. Examples of such antigen binding constructs are described in Example 31.

When the epitope-binding domain is a domain antibody, some domain antibodies may be suited to particular positions within the scaffold.

Domain antibodies of use in the present invention can be linked at the C-terminal end of the heavy chain and/or the light chain of conventional IgGs. In addition some dAbs can be linked to the C-terminal ends of both the heavy chain and the light chain of conventional antibodies.

In constructs where the N-terminus of dAbs are fused to an antibody constant domain (either C\textsubscript{\textit{H}}3 or CL), a peptide linker may help the dAb to bind to antigen. Indeed, the N-terminal end of a dAb is located closely to the complementarity-determining regions (CDRS) involved in antigen-binding activity. Thus a short peptide linker acts as a spacer between the epitope-binding, and the constant domain fo the
protein scaffold, which may allow the dAb CDRs to more easily reach the antigen, which may therefore bind with high affinity.

The surroundings in which dAbs are linked to the IgG will differ depending on which antibody chain they are fused to:

When fused at the C-terminal end of the antibody light chain of an IgG scaffold, each dAb is expected to be located in the vicinity of the antibody hinge and the Fc portion. It is likely that such dAbs will be located far apart from each other. In conventional antibodies, the angle between Fab fragments and the angle between each Fab fragment and the Fc portion can vary quite significantly. It is likely that - with mAb-AbAbs - the angle between the Fab fragments will not be widely different, whilst some angular restrictions may be observed with the angle between each Fab fragment and the Fc portion.

When fused at the C-terminal end of the antibody heavy chain of an IgG scaffold, each dAb is expected to be located in the vicinity of the $C_{\text{H}3}$ domains of the Fc portion. This is not expected to impact on the Fc binding properties to Fc receptors (e.g. $Fc\gamma R\alpha$, II, III an FcRn) as these receptors engage with the $C_{\text{H}2}$ domains (for the $Fc\gamma R\alpha$, II and III class of receptors) or with the hinge between the $C_{\text{H}2}$ and $C_{\text{H}3}$ domains (e.g. FcRn receptor). Another feature of such antigen-binding constructs is that both dAbs are expected to be spatially close to each other and provided that flexibility is provided by provision of appropriate linkers, these dAbs may even form homodimeric species, hence propagating the 'zipped' quaternary structure of the Fc portion, which may enhance stability of the construct.

Such structural considerations can aid in the choice of the most suitable position to link an epitope-binding domain, for example a dAb, on to a protein scaffold, for example an antibody.

The size of the antigen, its localization (in blood or on cell surface), its quaternary structure (monomeric or multimeric) can vary. Conventional antibodies are naturally designed to function as adaptor constructs due to the presence of the hinge region, wherein the orientation of the two antigen-binding sites at the tip of the Fab fragments can vary widely and hence adapt to the molecular feature of the antigen and its surroundings. In contrast dAbs linked to an antibody or other protein scaffold, for example a protein scaffold which comprises an antibody with no hinge region, may have less structural flexibility either directly or indirectly.

This is fairly reminiscent to multimerisation events observed in vivo with Ig domains such as Bence-Jones proteins (which are dimers of immunoglobulin light chains (Epp et al (1975) Biochemistry 14 p4943-4952; Huan et al (1994) Biochemistry 33 p14848-14857; Huang et al (1997) Mol Immunol 34 p1291-1301 ) and amyloid fibers (James et al. (2007) J Mol Biol. 367:603-8).

For example, it may be desirable to link domain antibodies that tend to dimerise in solution to the C-terminal end of the Fc portion in preference to the C-terminal end of the light chain as linking to the C-terminal end of the Fc will allow those dAbs to dimerise in the context of the antigen-binding construct of the invention.

The antigen-binding constructs of the present invention may comprise antigen-binding sites specific for a single antigen, or may have antigen-binding sites specific for two or more antigens, or for two or more epitopes on a single antigen, or there may be antigen-binding sites each of which is specific for a different epitope on the same or different antigens.

The antigen-binding sites can each have binding specificity for an antigen, such as human or animal proteins, including cytokines, growth factors, cytokine receptors, growth factor receptors, enzymes (e.g., proteases), co-factors for enzymes, DNA binding proteins, lipids and carbohydrates. Suitable targets, including cytokines, growth factors, cytokine receptors, growth factor receptors and other proteins include but are not limited to: ApoE, Apo-SAA, BDNF, Cardiotrophin-1, CEA, CD40, CD40 Ligand, CD56, CD38, CD138, EGF, EGF receptor, ENA-78, Eotaxin, Eotaxin-2, Exodus-2, FAPα, FGF-acidic, FGF-basic, fibroblast growth factor-10, FLT3 ligand, Fractalkine (CX3C), GDNF, G-CSF, GM-CSF, GF-β1, human serum albumin, insulin, IFN-γ, IGF-1, IGF-II, IL-1α, IL-1β, IL-1 receptor, IL-1 receptor type 1, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8 (72 a.a.), IL-8 (77 a.a.), IL-9, IL-10, IL-11, IL-12, IL-13, IL-15, IL-16, IL-17, IL-18 (IGIF), Inhibin α, Inhibin β, IP-10, keratinocyte growth factor-2 (KGF-2), KGF, Leptin, LIF, Lymphotactin, Mullerian inhibitory substance, monocyte colony inhibitory factor, monocyte attractant protein, M-CSF, c-fms, v-fmsMDC (67 a.a.), MDC (69 a.a.), MCP-1 (MCAF), MCP-2, MCP-3, MCP-4, MDC (67 a.a.), MDC (69 a.a.), MIG, MIP-1α, MIP-1β, MIP-3α, MIP-3β, MIP-4, myeloid progenitor inhibitor factor-1 (MPIF-1), NAP-2, Neurturin, Nerve growth factor, β-NGF, NT-3, NT-4, Oncostatin M, PDGF-AA, PDGF-AB, PDGF-BB, PF-4, RANTES, SDF1α, SDF1β, SCF, SCGF, stem cell factor (SCF), TARC, TGF-α, TGF-β, TGF-β2, TGF-β3, tumour necrosis factor (TNF), TNF-α, TNF-β, TNF receptor 1, TNF receptor 11, TNF-L1, TPO, VEGF, VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF receptor 1, VEGF receptor 2, VEGF receptor 3, GCP-2, GRO/MGSA, GRO-β, GRO-γ, HCC1, 1-309, HER 1, HER 2, HER 3, HER 4, serum albumin, vWF, amyloid proteins (e.g., amyloid alpha), MMP12, PDK1, IgE, and other targets disclosed herein. It will be appreciated that this list is by no means exhaustive.
In some embodiments, the protease resistant peptide or polypeptide binds a target in pulmonary tissue, such as a target selected from the group consisting of TNFR1, IL-1, IL-1R, IL-4, IL-4R, IL-5, IL-6, IL-6R, IL-8, IL-8R, IL-9, IL-9R, IL-10, IL-12, IL-12R, IL-13, IL-13Rα1, IL-13Rα2, IL-15, IL-15R, IL-16, IL-17R, IL-17, IL-18, IL-18R, IL-23 IL-23R, IL-25, CD2, CD4, CD11a, CD23, CD25, CD27, CD28, CD30, CD40, CD40L, CD56, CD138, ALK5, EGFR, FcERI, TGFβ, CCL2, CCL18, CEA, CR8, CTGF, CXCL12 (SDF-1), chymase, FGF, Furin, Endothelin-1, Eotaxins (e.g., Eotaxin, Eotaxin-2, Eotaxin-3), GM-CSF, ICAM-1, ICOS, IgE, IFNa, I-309, integrins, L-selectin, MIF, MIP4, MDC, MCP-1, MMPs, neutrophil elastase, osteopontin, OX-40, PARC, PD-1, RANTES, SCF, SDF-1, siglecδ, TARC, TGFB, Thrombin, Tim-1, TNF, TRANCE, Tryptase, VEGF, VLA-4, VCAM, α4β7, CCR2, CCR3, CCR4, CCR5, CCR7, CCR8, alphavbeta6, alphavbeta8, cMET, CD8, vWF, amyloid proteins (e.g., amyloid alpha), MMP12, PDK1, and IgE.

In particular, the antigen-binding constructs of the present invention may be useful in treating diseases associated with IL-13, IL-5 and IL-4, for example atopic dermatitis, allergic rhinitis, Crohn's disease, COPD, fibrotic diseases or disorders such as idiopathic pulmonary fibrosis, progressive systemic sclerosis, hepatic fibrosis, hepatic granulomas, schistosomiasis, leishmaniasis, diseases of cell cycle regulation such as Hodgkin's disease, B cell chronic lymphocytic leukaemia, for example the constructs may be useful in treating asthma.

Antigen-binding constructs of the present invention may be useful in treating diseases associated with growth factors such as IGF-1R, VEGF, and EGFR, for example cancer or rheumatoid arthritis, examples of types of cancer in which such therapies may be breast cancer, prostate cancer, lung cancer and myeloma.

Antigen-binding constructs of the present invention may be useful in treating diseases associated with TNF, for example arthritis, for example rheumatoid arthritis or osteoarthritis.

Antigen-binding constructs of the present invention may be useful in treating diseases associated with IL1-R, for example arthritis, for example rheumatoid arthritis or osteoarthritis.

Antigen-binding constructs of the present invention may be useful in treating diseases associated with CD20, for example autoimmune diseases such as psoriasis, inflammatory bowel disease, ulcerative colitis, crohns disease, rheumatoid arthritis, juvenile rheumatoid arthritis, systemic lupus erythematosus, neurodegenerative diseases, for example multiple sclerosis, neutrophil driven diseases, for example COPD, Wegeners vasculitis, cystic fibrosis, Sjogrens syndrome, chronic transplant rejection, type 1 diabetes graft versus host disease,
asthma, allergic diseases atopic dermatitis, eczematous dermatitis, allergic rhinitis, autoimmune diseases other including thyroiditis, spondyloarthopathy, ankylosing spondylitis, uveitis, polyarthritis or scleroderma, or cancer e.g. B- cell lymphomas or mature B cell neoplasm such as CLL or SLL.

Antigen-binding constructs of the present invention may be useful in treating diseases associated with IL-17 and IL-23, for example psoriasis, inflammatory bowel disease, ulcerative colitis, crohns disease, rheumatoid arthritis, juvenile rheumatoid arthritis, systemic lupus erythematosus, neurodegenerative diseases, for example multiple sclerosis, neutrophil driven diseases, for example COPD, Wegener's vasculitis, cystic fibrosis, Sjogrens syndrome, chronic transplant rejection, type 1 diabetes graft versus host disease, asthma, allergic diseases atopic dermatitis, eczematous dermatitis, allergic rhinitis, autoimmune diseases other including thyroiditis, spondyloarthopathy, ankylosing spondylitis, uveitis, polyarthritis or scleroderma.

The antigen binding constructs of the present invention may be produced by transfection of a host cell with an expression vector comprising the coding sequence for the antigen binding construct of the invention. An expression vector or recombinant plasmid is produced by placing these coding sequences for the antigen binding construct in operative association with conventional regulatory control sequences capable of controlling the replication and expression in, and/or secretion from, a host cell. Regulatory sequences include promoter sequences, e.g., CMV promoter, and signal sequences which can be derived from other known antibodies.

Similarly, a second expression vector can be produced having a DNA sequence which encodes a complementatory antigen binding construct light or heavy chain. In certain embodiments this second expression vector is identical to the first except insofar as the coding sequences and selectable markers are concerned, so to ensure as far as possible that each polypeptide chain is functionally expressed.

Alternatively, the heavy and light chain coding sequences for the antigen binding construct may reside on a single vector, for example in two expression cassettes in the same vector. A selected host cell is co-transfected by conventional techniques with both the first and second vectors (or simply transfected by a single vector) to create the transfected host cell of the invention comprising both the recombinant or synthetic light and heavy chains. The transfected cell is then cultured by conventional techniques to produce the engineered antigen binding construct of the invention. The antigen binding construct which includes the association of both the recombinant heavy chain and/or light chain is screened from culture by appropriate assay, such as ELISA or RIA. Similar conventional techniques may be employed to construct other antigen binding constructs.

Suitable vectors for the cloning and subcloning steps employed in the methods and construction of the compositions of this invention may be selected by one of skill in
the art. For example, the conventional pUC series of cloning vectors may be used. One vector, pUC19, is commercially available from supply houses, such as Amersham (Buckinghamshire, United Kingdom) or Pharmacia (Uppsala, Sweden). Additionally, any vector which is capable of replicating readily, has an abundance of cloning sites and selectable genes (e.g., antibiotic resistance), and is easily manipulated may be used for cloning. Thus, the selection of the cloning vector is not a limiting factor in this invention.

The expression vectors may also be characterized by genes suitable for amplifying expression of the heterologous DNA sequences, e.g., the mammalian dihydrofolate reductase gene (DHFR). Other preferable vector sequences include a poly A signal sequence, such as from bovine growth hormone (BGH) and the betaglobin promoter sequence (betaglopro). The expression vectors useful herein may be synthesized by techniques well known to those skilled in this art.

The components of such vectors, e.g. replicons, selection genes, enhancers, promoters, signal sequences and the like, may be obtained from commercial or natural sources or synthesized by known procedures for use in directing the expression and/or secretion of the product of the recombinant DNA in a selected host. Other appropriate expression vectors of which numerous types are known in the art for mammalian, bacterial, insect, yeast, and fungal expression may also be selected for this purpose.

The present invention also encompasses a cell line transfected with a recombinant plasmid containing the coding sequences of the antigen binding constructs of the present invention. Host cells useful for the cloning and other manipulations of these cloning vectors are also conventional. However, cells from various strains of E. coli may be used for replication of the cloning vectors and other steps in the construction of antigen binding constructs of this invention. Suitable host cells or cell lines for the expression of the antigen binding constructs of the invention include mammalian cells such as NSO, Sp2/0, CHO (e.g. DG44), COS, HEK, a fibroblast cell (e.g., 3T3), and myeloma cells, for example it may be expressed in a CHO or a myeloma cell. Human cells may be used, thus enabling the molecule to be modified with human glycosylation patterns. Alternatively, other eukaryotic cell lines may be employed. The selection of suitable mammalian host cells and methods for transformation, culture, amplification, screening and product production and purification are known in the art. See, e.g., Sambrook et al., cited above.

Bacterial cells may prove useful as host cells suitable for the expression of the recombinant Fabs or other embodiments of the present invention (see, e.g., Plückthun, A., Immunol. Rev., 130:151-188 (1992)). However, due to the tendency of proteins expressed in bacterial cells to be in an unfolded or improperly folded form or in a non-glycosylated form, any recombinant Fab produced in a bacterial cell would have to be screened for retention of antigen binding ability. If the molecule expressed by the bacterial cell was produced in a properly folded form, that bacterial cell would be a desirable host, or in alternative embodiments the molecule may
express in the bacterial host and then be subsequently re-folded. For example, various strains of E. coli used for expression are well-known as host cells in the field of biotechnology. Various strains of B. subtilis, Streptomyces, other bacilli and the like may also be employed in this method.

Where desired, strains of yeast cells known to those skilled in the art are also available as host cells, as well as insect cells, e.g. Drosophila and Lepidoptera and viral expression systems. See, e.g. Miller et al., Genetic Engineering, 8:277-298, Plenum Press (1986) and references cited therein.

The general methods by which the vectors may be constructed, the transfection methods required to produce the host cells of the invention, and culture methods necessary to produce the antigen binding construct of the invention from such host cell may all be conventional techniques. Typically, the culture method of the present invention is a serum-free culture method, usually by culturing cells serum-free in suspension. Likewise, once produced, the antigen binding constructs of the invention may be purified from the cell culture contents according to standard procedures of the art, including ammonium sulfate precipitation, affinity columns, column chromatography, gel electrophoresis and the like. Such techniques are within the skill of the art and do not limit this invention. For example, preparation of altered antibodies are described in WO 99/58679 and WO 96/16990.

Yet another method of expression of the antigen binding constructs may utilize expression in a transgenic animal, such as described in U. S. Patent No. 4,873,316. This relates to an expression system using the animal's casein promoter which when transgenically incorporated into a mammal permits the female to produce the desired recombinant protein in its milk.

In a further aspect of the invention there is provided a method of producing an antibody of the invention which method comprises the step of culturing a host cell transformed or transfected with a vector encoding the light and/or heavy chain of the antibody of the invention and recovering the antibody thereby produced.

In accordance with the present invention there is provided a method of producing an antigen binding construct of the present invention which method comprises the steps of:

(a) providing a first vector encoding a heavy chain of the antigen binding construct;
(b) providing a second vector encoding a light chain of the antigen binding construct;
(c) transforming a mammalian host cell (e.g. CHO) with said first and second vectors;
(d) culturing the host cell of step (c) under conditions conducive to the secretion of the antigen binding construct from said host cell into said culture media;
(e) recovering the secreted antigen binding construct of step (d).
Once expressed by the desired method, the antigen binding construct is then examined for in vitro activity by use of an appropriate assay. Presently conventional ELISA assay formats are employed to assess qualitative and quantitative binding of the antigen binding construct to its target. Additionally, other in vitro assays may also be used to verify neutralizing efficacy prior to subsequent human clinical studies performed to evaluate the persistence of the antigen binding construct in the body despite the usual clearance mechanisms.

The dose and duration of treatment relates to the relative duration of the molecules of the present invention in the human circulation, and can be adjusted by one of skill in the art depending upon the condition being treated and the general health of the patient. It is envisaged that repeated dosing (e.g. once a week or once every two weeks) over an extended time period (e.g. four to six months) maybe required to achieve maximal therapeutic efficacy.

The mode of administration of the therapeutic agent of the invention may be any suitable route which delivers the agent to the host. The antigen binding constructs, and pharmaceutical compositions of the invention are particularly useful for parenteral administration, i.e., subcutaneously (s.c), intrathecal\(^{\text{a}}\), intraperitoneal\(^{\text{b}}\), intramuscularly (i.m.), intravenously (i.v.), or intranasally. Therapeutic agents of the invention may be prepared as pharmaceutical compositions containing an effective amount of the antigen binding construct of the invention as an active ingredient in a pharmaceutically acceptable carrier. In the prophylactic agent of the invention, an aqueous suspension or solution containing the antigen binding construct, preferably buffered at physiological pH, in a form ready for injection is preferred. The compositions for parenteral administration will commonly comprise a solution of the antigen binding construct of the invention or a cocktail thereof dissolved in a pharmaceutically acceptable carrier, preferably an aqueous carrier. A variety of aqueous carriers may be employed, e.g., 0.9% saline, 0.3% glycine, and the like. These solutions may be made sterile and generally free of particulate matter. These solutions may be sterilized by conventional, well known sterilization techniques (e.g., filtration). The compositions may contain pharmaceutically acceptable auxiliary substances as required to approximate physiological conditions such as pH adjusting and buffering agents, etc. The concentration of the antigen binding construct of the invention in such pharmaceutical formulation can vary widely, i.e., from less than about 0.5%, usually at or at least about 1% to as much as 15 or 20% by weight and will be selected primarily based on fluid volumes, viscosities, etc., according to the particular mode of administration selected.

It is preferred that the therapeutic agent of the invention, when in a pharmaceutical preparation, be present in unit dose forms. The appropriate therapeutically effective dose will be determined readily by those of skill in the art. Suitable doses may be calculated for patients according to their weight, for example suitable doses may be in the range of 0.01 to 20mg/kg, for example 0.1 to 20mg/kg, for example 1 to 20mg/kg, for example 10 to 20mg/kg or for example 1 to 15mg/kg, for example 10 to 15mg/kg. To effectively treat conditions of use in the present invention in a human, suitable doses may be within the range of 0.01 to 1000 mg, for example 0.1 to 1000mg, for example 0.1 to 500mg, for example 500mg, for example 0.1 to 100mg, or 0.1 to 80mg, or 0.1 to 60mg, or 0.1 to 40mg, or for example 1 to 100mg, or 1 to 50mg, of an antigen binding construct of this invention, which may be administered...
parenterally, for example subcutaneously, intravenously or intramuscularly. Such dose may, if necessary, be repeated at appropriate time intervals selected as appropriate by a physician.

The antigen binding constructs described herein can be lyophilized for storage and reconstituted in a suitable carrier prior to use. This technique has been shown to be effective with conventional immunoglobulins and art-known lyophilization and reconstitution techniques can be employed.

There are several methods known in the art which can be used to find epitope-binding domains of use in the present invention.

The term "library" refers to a mixture of heterogeneous polypeptides or nucleic acids. The library is composed of members, each of which has a single polypeptide or nucleic acid sequence. To this extent, "library" is synonymous with "repertoire."

Sequence differences between library members are responsible for the diversity present in the library. The library may take the form of a simple mixture of polypeptides or nucleic acids, or may be in the form of organisms or cells, for example bacteria, viruses, animal or plant cells and the like, transformed with a library of nucleic acids. In one example, each individual organism or cell contains only one or a limited number of library members. Advantageously, the nucleic acids are incorporated into expression vectors, in order to allow expression of the polypeptides encoded by the nucleic acids. In a one aspect, therefore, a library may take the form of a population of host organisms, each organism containing one or more copies of an expression vector containing a single member of the library in nucleic acid form which can be expressed to produce its corresponding polypeptide member. Thus, the population of host organisms has the potential to encode a large repertoire of diverse polypeptides.

A "universal framework" is a single antibody framework sequence corresponding to the regions of an antibody conserved in sequence as defined by Kabat ("Sequences of Proteins of Immunological Interest", US Department of Health and Human Services) or corresponding to the human germline immunoglobulin repertoire or structure as defined by Chothia and Lesk, (1987) J. Mol. Biol. 196:910-917. There may be a single framework, or a set of such frameworks, which has been found to permit the derivation of virtually any binding specificity though variation in the hypervariable regions alone.

Amino acid and nucleotide sequence alignments and homology, similarity or identity, as defined herein are in one embodiment prepared and determined using the algorithm BLAST 2 Sequences, using default parameters (Tatusova, T.A. et al., FEMS Microbiol Lett, 174:187-188 (1999)).

The epitope binding domain(s) and antigen binding sites can each have binding specificity for a generic ligand or any desired target ligand, such as human or animal
proteins, including cytokines, growth factors, cytokine receptors, growth factor receptors, enzymes (e.g., proteases), co-factors for enzymes, DNA binding proteins, lipids and carbohydrates. Suitable targets, including cytokines, growth factors, cytokine receptors, growth factor receptors and other proteins include but are not limited to: ApoE, Apo-SAA, BDNF, Cardiotrophin-1, CEA, CD40, CD40 Ligand, CD56, CD38, CD138, EGF, EGF receptor, ENA-78, Eotaxin, Eotaxin-2, Exodus-2, FAPα, FGF-basic, fibroblast growth factor-10, FLT3 ligand, Fractalkine (CX3C), GDNF, G-CSF, GM-CSF, GF-β1, human serum albumin, insulin, IFN-γ, IGF-1, IGF-II, IL-1α, IL-1β, IL-1 receptor, IL-1 receptor type 1, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8 (72 a.a.), IL-8 (77 a.a.), IL-9, IL-10, IL-11, IL-12, IL-13, IL-15, IL-16, IL-17, IL-18 (IGIF), Inhibin α, Inhibin β, IP-10, keratinocyte growth factor-2 (KGF-2), KGF, Leptin, LIF, Lymphotactin, Mullerian inhibitory factor, monocyte colony inhibitory factor, monocyte attractant protein, M-CSF, c-fms, v-fmsMDC (67 a.a.), MDC (69 a.a.), MCP-1 (MCAF), MCP-2, MCP-3, MCP-4, MDC (67 a.a.), MDC (69 a.a.), MIG, MIP-1α, MIP-1β, MIP-3α, MIP-3β, MIP-4, myeloid progenitor inhibitor factor-1 (MPIF-1), NAP-2, Neurturin, Nerve growth factor, β-NGF, NT-3, NT-4, Oncostatin M, PDGF-AA, PDGF-AB, PDGF-BB, PF-4, RANTES, SDF1α, SDF1β, SCGF, stem cell factor (SCF), TARC, TGF-α, TGF-β, TGF-β2, TGF-β3, tumour necrosis factor (TNF), TNF-α, TNF-β, TNF receptor I, TNF receptor II, TNIL-1, TPO, VEGF, VEGF A, VEGF B, VEGF C, VEGF D, VEGF receptor 1, VEGF receptor 2, VEGF receptor 3, GCP-2, GRO/MGSA, GRO-β, GRO-γ, HCC1, 1-309, HER 1, HER 2, HER 3, HER 4, serum albumin, vWF, amyloid proteins (e.g., amyloid alpha), MMP12, PDK1, IgE, and other targets disclosed herein. It will be appreciated that this list is by no means exhaustive.

In some embodiments, binding is to a target in pulmonary tissue, such as a target selected from the group consisting of TNFR1, IL-1, IL-1R, IL-4, IL-4R, IL-5, IL-6, IL-6R, IL-8, IL-8R, IL-9, IL-9R, IL-10, IL-12, IL-12R, IL-13, IL-13Rα1, IL-13Ra2, IL-15, IL-15R, IL-16, IL-17R, IL-17, IL-18, IL-18R, IL-23 IL-23R, IL-25, CD2, CD4, CD1a, CD23, CD25, CD27, CD28, CD30, CD40, CD40L, CD56, CD138, ALK5, EGFR, FcERI, TGFβ, CCL2, CCL18, CEA, CR8, CTGF, CXCL12 (SDF-1), chymase, FGF, Furin, Endothelin-1, Eotaxins (e.g., Eotaxin, Eotaxin-2, Eotaxin-3), GM-CSF, ICAM-1, ICOS, IgE, IFNa, I-309, integrins, L-selectin, MIF, MIP4, MDC, MCP-1, MMPs, neutrophil elastase, osteopontin, OX-40, PARC, PD-1, RANTES, SCF, SDF-1, siglecδ, TARC, TGFβ, Thrombin, Tim-1, TNF, TRANCE, Trypsate, VEGF, VLA-4, VCAM, α4β7, CCR2, CCR3, CCR4, CCR5, CCR7, CCR8, alphavbeta 6, alphavbeta δ, cMET, CD8, vWF, amyloid proteins (e.g., amyloid alpha), MMP12, PDK1, and IgE.

When a display system (e.g., a display system that links coding function of a nucleic acid and functional characteristics of the peptide or polypeptide encoded by the nucleic acid) is used in the methods described herein, e.g in the selection of a dAb or other epitope binding domain, it is frequently advantageous to amplify or increase the copy number of the nucleic acids that encode the selected peptides or polypeptides. This provides an efficient way of obtaining sufficient quantities of nucleic acids and/or
peptides or polypeptides for additional rounds of selection, using the methods described herein or other suitable methods, or for preparing additional repertoires (e.g., affinity maturation repertoires). Thus, in some embodiments, the methods of selecting epitope binding domains comprises using a display system (e.g., that links coding function of a nucleic acid and functional characteristics of the peptide or polypeptide encoded by the nucleic acid, such as phage display) and further comprises amplifying or increasing the copy number of a nucleic acid that encodes a selected peptide or polypeptide. Nucleic acids can be amplified using any suitable methods, such as by phage amplification, cell growth or polymerase chain reaction.

In one example, the methods employ a display system that links the coding function of a nucleic acid and physical, chemical and/or functional characteristics of the polypeptide encoded by the nucleic acid. Such a display system can comprise a plurality of replicable genetic packages, such as bacteriophage or cells (bacteria). The display system may comprise a library, such as a bacteriophage display library. Bacteriophage display is an example of a display system. A number of suitable bacteriophage display systems (e.g., monovalent display and multivalent display systems) have been described. (See, e.g., Griffiths et al., U.S. Patent No. 6,555,313 B1 (incorporated herein by reference); Johnson et al., U.S. Patent No. 5,733,743 (incorporated herein by reference); McCafferty et al., U.S. Patent No. 5,969,108 (incorporated herein by reference); Mulligan-Kehoe, U.S. Patent No. 5,702,892 (Incorporated herein by reference); Winter, G. et al, Annu. Rev. Immunol. /2:433-455 (1994); Soumillon, P. et al., Appl. Biochem. Biotechnol. 47(2-3):175-189 (1994); Castagnoli, L. et al., Comb. Chem. High Throughput Screen, 4(2):121-133 (2001).) The peptides or polypeptides displayed in a bacteriophage display system can be displayed on any suitable bacteriophage, such as a filamentous phage (e.g., fd, M13, F1), a lytic phage (e.g., T4, T7, lambda), or an RNA phage (e.g., MS2), for example. Generally, a library of phage that displays a repertoire of peptides or phagepolypeptides, as fusion proteins with a suitable phage coat protein (e.g., fd pill protein), is produced or provided. The fusion protein can display the peptides or polypeptides at the tip of the phage coat protein, or if desired at an internal position. For example, the displayed peptide or polypeptide can be present at a position that is amino-terminal to domain 1 of pill. (Domain 1 of pill is also referred to as N1.) The displayed polypeptide can be directly fused to pill (e.g., the N-terminus of domain 1 of pill) or fused to pill using a linker. If desired, the fusion can further comprise a tag (e.g., myc epitope, His tag). Libraries that comprise a repertoire of peptides or polypeptides that are displayed as fusion proteins with a phage coat protein, can be produced using any suitable methods, such as by introducing a library of phage vectors or phagemid vectors encoding the displayed peptides or polypeptides into suitable host bacteria, and culturing the resulting bacteria to produce phage (e.g., using a suitable helper phage or complementing plasmid if desired). The library of
phage can be recovered from the culture using any suitable method, such as precipitation and centrifugation. The display system can comprise a repertoire of peptides or polypeptides that contains any desired amount of diversity. For example, the repertoire can contain peptides or polypeptides that have amino acid sequences that correspond to naturally occurring polypeptides expressed by an organism, group of organisms, desired tissue or desired cell type, or can contain peptides or polypeptides that have random or randomized amino acid sequences. If desired, the polypeptides can share a common core or scaffold. For example, all polypeptides in the repertoire or library can be based on a scaffold selected from protein A, protein L, protein G, a fibronectin domain, an anticalin, CTLA4, a desired enzyme (e.g., a polymerase, a cellulase), or a polypeptide from the immunoglobulin superfamily, such as an antibody or antibody fragment (e.g., an antibody variable domain). The polypeptides in such a repertoire or library can comprise defined regions of random or randomized amino acid sequence and regions of common amino acid sequence. In certain embodiments, all or substantially all polypeptides in a repertoire are of a desired type, such as a desired enzyme (e.g., a polymerase) or a desired antigen-binding fragment of an antibody (e.g., human V\text{H} or human V\text{L}). In some embodiments, the polypeptide display system comprises a repertoire of polypeptides wherein each polypeptide comprises an antibody variable domain. For example, each polypeptide in the repertoire can contain a V\text{H}, a V\text{L} or an Fv (e.g., a single chain Fv). Amino acid sequence diversity can be introduced into any desired region of a peptide or polypeptide or scaffold using any suitable method. For example, amino acid sequence diversity can be introduced into a target region, such as a complementarity determining region of an antibody variable domain or a hydrophobic domain, by preparing a library of nucleic acids that encode the diversified polypeptides using any suitable mutagenesis methods (e.g., low fidelity PCR, oligonucleotide-mediated or site directed mutagenesis, diversification using NNK codons) or any other suitable method. If desired, a region of a polypeptide to be diversified can be randomized. The size of the polypeptides that make up the repertoire is largely a matter of choice and uniform polypeptide size is not required. The polypeptides in the repertoire may have at least tertiary structure (form at least one domain).

Selection/Isolation/Recovery

An epitope binding domain or population of domains can be selected, isolated and/or recovered from a repertoire or library (e.g., in a display system) using any suitable method. For example, a domain is selected or isolated based on a selectable characteristic (e.g., physical characteristic, chemical characteristic, functional characteristic). Suitable selectable functional characteristics include biological activities of the peptides or polypeptides in the repertoire, for example, binding to a generic ligand (e.g., a superantigen), binding to a target ligand (e.g., an antigen, an epitope, a substrate), binding to an antibody (e.g., through an epitope expressed on a
peptide or polypeptide), and catalytic activity. (See, e.g., Tomlinson et al., WO 99/20749; WO 01/57065; WO 99/58655.) In some embodiments, the protease resistant peptide or polypeptide is selected and/or isolated from a library or repertoire of peptides or polypeptides in which substantially all domains share a common selectable feature. For example, the domain can be selected from a library or repertoire in which substantially all domains bind a common generic ligand, bind a common target ligand, bind (or are bound by) a common antibody, or possess a common catalytic activity. This type of selection is particularly useful for preparing a repertoire of domains that are based on a parental peptide or polypeptide that has a desired biological activity, for example, when performing affinity maturation of an immunoglobulin single variable domain. Selection based on binding to a common generic ligand can yield a collection or population of domains that contain all or substantially all of the domains that were components of the original library or repertoire. For example, domains that bind a target ligand or a generic ligand, such as protein A, protein L or an antibody, can be selected, isolated and/or recovered by panning or using a suitable affinity matrix. Panning can be accomplished by adding a solution of ligand (e.g., generic ligand, target ligand) to a suitable vessel (e.g., tube, petri dish) and allowing the ligand to become deposited or coated onto the walls of the vessel. Excess ligand can be washed away and domains can be added to the vessel and the vessel maintained under conditions suitable for peptides or polypeptides to bind the immobilized ligand. Unbound domains can be washed away and bound domains can be recovered using any suitable method, such as scraping or lowering the pH, for example. Suitable ligand affinity matrices generally contain a solid support or bead (e.g., agarose) to which a ligand is covalently or noncovalently attached. The affinity matrix can be combined with peptides or polypeptides (e.g., a repertoire that has been incubated with protease) using a batch process, a column process or any other suitable process under conditions suitable for binding of domains to the ligand on the matrix, domains that do not bind the affinity matrix can be washed away and bound domains can be eluted and recovered using any suitable method, such as elution with a lower pH buffer, with a mild denaturing agent (e.g., urea), or with a peptide or domain that competes for binding to the ligand. In one example, a biotinylated target ligand is combined with a repertoire under conditions suitable for domains in the repertoire to bind the target ligand. Bound domains are recovered using immobilized avidin or streptavidin (e.g., on a bead). In some embodiments, the generic or target ligand is an antibody or antigen binding fragment thereof. Antibodies or antigen binding fragments that bind structural features of peptides or polypeptides that are substantially conserved in the peptides or polypeptides of a library or repertoire are particularly useful as generic ligands. Antibodies and antigen binding fragments suitable for use as ligands for isolating, selecting and/or recovering protease resistant peptides or polypeptides can be monoclonal or polyclonal and can be prepared using any suitable method.
LIBRARIES/REPERTOIRES

Libraries that encode and/or contain protease epitope binding domains can be
prepared or obtained using any suitable method. A library can be designed to
encode domains based on a domain or scaffold of interest (e.g., a domain selected
from a library) or can be selected from another library using the methods described
herein. For example, a library enriched in domains can be prepared using a suitable
polypeptide display system.

Libraries that encode a repertoire of a desired type of domain can readily be
produced using any suitable method. For example, a nucleic acid sequence that
encodes a desired type of polypeptide (e.g., an immunoglobulin variable domain) can
be obtained and a collection of nucleic acids that each contain one or more mutations
can be prepared, for example by amplifying the nucleic acid using an error-prone
polymerase chain reaction (PCR) system, by chemical mutagenesis (Deng et al., J.
Biol., 260:359 (1996)).

In other embodiments, particular regions of the nucleic acid can be targeted for
diversification. Methods for mutating selected positions are also well known in the art
and include, for example, the use of mismatched oligonucleotides or degenerate
oligonucleotides, with or without the use of PCR. For example, synthetic antibody
libraries have been created by targeting mutations to the antigen binding loops.
Random or semi-random antibody H3 and L3 regions have been appended to
germline immunoglobulin V gene segments to produce large libraries with unmutated
framework regions (Hoogenboom and Winter (1992) supra; Nissim et al. (1994)
supra; Griffiths et al. (1994) supra; DeKruif et al. (1995) supra). Such diversification
has been extended to include some or all of the other antigen binding loops (Crameri
Morphosys, WO 97/08320, supra). In other embodiments, particular regions of the
nucleic acid can be targeted for diversification by, for example, a two-step PCR
strategy employing the product of the first PCR as a "mega-primer." (See, e.g.,
Landt, O. et al., Gene 96:125-128 (1990).) Targeted diversification can also be
accomplished, for example, by SOE PCR. (See, e.g., Horton, R.M. et al., Gene
77:61-68 (1989).)

Sequence diversity at selected positions can be achieved by altering the coding
sequence which specifies the sequence of the polypeptide such that a number of
possible amino acids (e.g., all 20 or a subset thereof) can be incorporated at that
position. Using the IUPAC nomenclature, the most versatile codon is NNK, which
encodes all amino acids as well as the TAG stop codon. The NNK codon may be
used in order to introduce the required diversity. Other codons which achieve the
same ends are also of use, including the NNN codon, which leads to the production
of the additional stop codons TGA and TAA. Such a targeted approach can allow the
full sequence space in a target area to be explored.

Some libraries comprise domains that are members of the immunoglobulin
superfamily (e.g., antibodies or portions thereof). For example the libraries can
comprise domains that have a known main-chain conformation. (See, e.g., Tomlinson et al., WO 99/20749.) Libraries can be prepared in a suitable plasmid or vector. As used herein, vector refers to a discrete element that is used to introduce heterologous DNA into cells for the expression and/or replication thereof.

Any suitable vector can be used, including plasmids (e.g., bacterial plasmids), viral or bacteriophage vectors, artificial chromosomes and episomal vectors. Such vectors may be used for simple cloning and mutagenesis, or an expression vector can be used to drive expression of the library. Vectors and plasmids usually contain one or more cloning sites (e.g., a polylinker), an origin of replication and at least one selectable marker gene. Expression vectors can further contain elements to drive transcription and translation of a polypeptide, such as an enhancer element, promoter, transcription termination signal, signal sequences, and the like. These elements can be arranged in such a way as to be operably linked to a cloned insert encoding a polypeptide, such that the polypeptide is expressed and produced when such an expression vector is maintained under conditions suitable for expression (e.g., in a suitable host cell).

Cloning and expression vectors generally contain nucleic acid sequences that enable the vector to replicate in one or more selected host cells. Typically in cloning vectors, this sequence is one that enables the vector to replicate independently of the host chromosomal DNA and includes origins of replication or autonomously replicating sequences. Such sequences are well known for a variety of bacteria, yeast and viruses. The origin of replication from the plasmid pBR322 is suitable for most Gram-negative bacteria, the 2 micron plasmid origin is suitable for yeast, and various viral origins (e.g. SV40, adenovirus) are useful for cloning vectors in mammalian cells.

Generally, the origin of replication is not needed for mammalian expression vectors, unless these are used in mammalian cells able to replicate high levels of DNA, such as COS cells. Cloning or expression vectors can contain a selection gene also referred to as selectable marker. Such marker genes encode a protein necessary for the survival or growth of transformed host cells grown in a selective culture medium. Host cells not transformed with the vector containing the selection gene will therefore not survive in the culture medium. Typical selection genes encode proteins that confer resistance to antibiotics and other toxins, e.g. ampicillin, neomycin, methotrexate or tetracycline, complement auxotrophic deficiencies, or supply critical nutrients not available in the growth media.

Suitable expression vectors can contain a number of components, for example, an origin of replication, a selectable marker gene, one or more expression control elements, such as a transcription control element (e.g., promoter, enhancer, terminator) and/or one or more translation signals, a signal sequence or leader sequence, and the like. Expression control elements and a signal or leader sequence, if present, can be provided by the vector or other source. For example, the transcriptional and/or translational control sequences of a cloned nucleic acid encoding an antibody chain can be used to direct expression.
A promoter can be provided for expression in a desired host cell. Promoters can be constitutive or inducible. For example, a promoter can be operably linked to a nucleic acid encoding an antibody, antibody chain or portion thereof, such that it directs transcription of the nucleic acid. A variety of suitable promoters for procaryotic (e.g., the β-lactamase and lactose promoter systems, alkaline phosphatase, the tryptophan (trp) promoter system, lac, tac, T3, T7 promoters for E. coli) and eucaryotic (e.g., simian virus 40 early or late promoter, Rous sarcoma virus long terminal repeat promoter, cytomegalovirus promoter, adenovirus late promoter, EG-la promoter) hosts are available.

In addition, expression vectors typically comprise a selectable marker for selection of host cells carrying the vector, and, in the case of a replicable expression vector, an origin of replication. Genes encoding products which confer antibiotic or drug resistance are common selectable markers and may be used in procaryotic (e.g., β-lactamase gene (ampicillin resistance), Tet gene for tetracycline resistance) and eucaryotic cells (e.g., neomycin (G418 or geneticin), gpt (mycophenolic acid), ampicillin, or hygromycin resistance genes). Dihydrofolate reductase marker genes permit selection with methotrexate in a variety of hosts. Genes encoding the gene product of auxotrophic markers of the host (e.g., LEU2, URA3, HIS3) are often used as selectable markers in yeast. Use of viral (e.g., baculovirus) or phage vectors, and vectors which are capable of integrating into the genome of the host cell, such as retroviral vectors, are also contemplated.

Suitable expression vectors for expression in procaryotic (e.g., bacterial cells such as E. coli) or mammalian cells include, for example, a pET vector (e.g., pET-12a, pET-36, pET-37, pET-39, pET-40, Novagen and others), a phage vector (e.g., pCANTAB 5 E. Pharmacia), pRIT2T (Protein A fusion vector, Pharmacia), pCDM8, pCDNA1 .1/amp, pCDNA3.1 , pRc/RSV, pEF-1 (Invitrogen, Carlsbad, CA), pCMV-SCRIPT, pFB, pSG5, pXT1 (Stratagene, La Jolla, CA), pCDEF3 (Goldman, L.A., et ai, Biotechniques, 27:1013-1015 (1996)), pSVSPORT (GibcoBRL, Rockville, MD), pEF-Bos (Mizushima, S., et ai, Nucleic Acids Res., 18:5322 (1990)) and the like.

Expression vectors which are suitable for use in various expression hosts, such as procaryotic cells (E. coli), insect cells (Drosophila Schneider S2 cells, S9), yeast (P. methanolica, P. pastoris, S. cerevisiae) and mammalian cells (eg, COS cells) are available.

Some examples of vectors are expression vectors that enable the expression of a nucleotide sequence corresponding to a polypeptide library member. Thus, selection with generic and/or target ligands can be performed by separate propagation and expression of a single clone expressing the polypeptide library member. As described above, a particular selection display system is bacteriophage display. Thus, phage or phagemid vectors may be used, for example vectors may be phagemid vectors which have an E. coli origin of replication (for double stranded replication) and also a phage origin of replication (for production of single-stranded DNA). The manipulation and expression of such vectors is well known in the art (Hoogenboom and Winter (1992) supra; Nissim et ai (1994) supra). Briefly, the
vector can contain a β-lactamase gene to confer selectivity on the phagemid and a
lac promoter upstream of an expression cassette that can contain a suitable leader
sequence, a multiple cloning site, one or more peptide tags, one or more TAG stop
codonts and the phage protein pill. Thus, using various suppressor and non-
suppressor strains of E. coli and with the addition of glucose, iso-propyl thio-β-D-
galactoside (IPTG) or a helper phage, such as VCS M13, the vector is able to
replicate as a plasmid with no expression, produce large quantities of the polypeptide
library member only or product phage, some of which contain at least one copy of the
polypeptide-pill fusion on their surface.

Antibody variable domains may comprise a target ligand binding site and/or a generic
ligand binding site. In certain embodiments, the generic ligand binding site is a
binding site for a superantigen, such as protein A, protein L or protein G. The
variable domains can be based on any desired variable domain, for example a
human VH (e.g., V\_H 1a, V\_H 1b, V\_H 2, V\_H 3, V\_H 4, V\_H 5, V\_H 6), a human V\_L (e.g., V\_L1, V\_LII, V\_LIII, V\_LV, V\_LV1 or V\_K1) or a human V\_K (e.g., V\_K2, V\_K3, V\_K4, V\_K5, V\_K6, V\_K7, V\_K8, V\_K9 or V\_K10).

A still further category of techniques involves the selection of repertoires in artificial
compartments, which allow the linkage of a gene with its gene product. For example,
a selection system in which nucleic acids encoding desirable gene products may be
selected in microcapsules formed by water-in-oil emulsions is described in
652-6. Genetic elements encoding a gene product having a desired activity are
compartmentalised into microcapsules and then transcribed and/or translated to
produce their respective gene products (RNA or protein) within the microcapsules.
Genetic elements which produce gene product having desired activity are
subsequently sorted. This approach selects gene products of interest by detecting
the desired activity by a variety of means.

**Characterisation of the epitope binding domains.**

The binding of a domain to its specific antigen or epitope can be tested by methods
which will be familiar to those skilled in the art and include ELISA. In one example,
binding is tested using monoclonal phage ELISA.

Phage ELISA may be performed according to any suitable procedure: an exemplary
protocol is set forth below.

Populations of phage produced at each round of selection can be screened for
binding by ELISA to the selected antigen or epitope, to identify "polyclonal" phage
antibodies. Phage from single infected bacterial colonies from these populations can
then be screened by ELISA to identify "monoclonal" phage antibodies. It is also
desirable to screen soluble antibody fragments for binding to antigen or epitope, and
this can also be undertaken by ELISA using reagents, for example, against a C- or N-terminal tag (see for example Winter et al. (1994) Ann. Rev. Immunology 12, 433-55 and references cited therein.

5 The diversity of the selected phage monoclonal antibodies may also be assessed by gel electrophoresis of PCR products (Marks et al. 1991, supra; Nissim et al. 1994 supra), probing (Tomlinson et al., 1992) J. Mol. Biol. 227, 776) or by sequencing of the vector DNA.

10 E. Structure of dAbs

In the case that the dAbs are selected from V-gene repertoires selected for instance using phage display technology as herein described, then these variable domains comprise a universal framework region, such that is they may be recognised by a specific generic ligand as herein defined. The use of universal frameworks, generic ligands and the like is described in WO99/20749.

Where V-gene repertoires are used variation in polypeptide sequence may be located within the structural loops of the variable domains. The polypeptide sequences of either variable domain may be altered by DNA shuffling or by mutation in order to enhance the interaction of each variable domain with its complementary pair. DNA shuffling is known in the art and taught, for example, by Stemmer, 1994, Nature 370: 389-391 and U.S. Patent No. 6,297,053, both of which are incorporated herein by reference. Other methods of mutagenesis are well known to those of skill in the art.

Scaffolds for use in Constructing dAbs

i. Selection of the main-chain conformation

The members of the immunoglobulin superfamily all share a similar fold for their polypeptide chain. For example, although antibodies are highly diverse in terms of their primary sequence, comparison of sequences and crystallographic structures has revealed that, contrary to expectation, five of the six antigen binding loops of antibodies (H1, H2, L1, L2, L3) adopt a limited number of main-chain conformations, or canonical structures (Chothia and Lesk (1987) J. Mol. Biol., 196: 901; Chothia et al. (1989) Nature, 342: 877). Analysis of loop lengths and key residues has therefore enabled prediction of the main-chain conformations of H1, H2, L1, L2 and L3 found in the majority of human antibodies (Chothia et al. (1992) J. Mol. Biol., 227: 799; Tomlinson et al. (1995) EMBO J., 14: 4628; Williams et al. (1996) J. Mol. Biol., 264: 220). Although the H3 region is much more diverse in terms of sequence, length and structure (due to the use of D segments), it also forms a limited number of main-chain conformations for short loop lengths which depend on the length and the presence of particular residues, or types of residue, at key positions in the loop and

The dAbs are advantageously assembled from libraries of domains, such as libraries of VH domains and/or libraries of VL domains. In one aspect, libraries of domains are designed in which certain loop lengths and key residues have been chosen to ensure that the main-chain conformation of the members is known. Advantageously, these are real conformations of immunoglobulin superfamily molecules found in nature, to minimise the chances that they are non-functional, as discussed above. Germline V gene segments serve as one suitable basic framework for constructing antibody or T-cell receptor libraries; other sequences are also of use. Variations may occur at a low frequency, such that a small number of functional members may possess an altered main-chain conformation, which does not affect its function.

Canonical structure theory is also of use to assess the number of different main-chain conformations encoded by ligands, to predict the main-chain conformation based on ligand sequences and to chose residues for diversification which do not affect the canonical structure. It is known that, in the human VK domain, the L1 loop can adopt one of four canonical structures, the L2 loop has a single canonical structure and that 90% of human VK domains adopt one of four or five canonical structures for the L3 loop (Tomlinson et al. (1995) supra); thus, in the VK domain alone, different canonical structures can combine to create a range of different main-chain conformations. Given that the VL domain encodes a different range of canonical structures for the L1, L2 and L3 loops and that VK and VL domains can pair with any VH domain which can encode several canonical structures for the H1 and H2 loops, the number of canonical structure combinations observed for these five loops is very large. This implies that the generation of diversity in the main-chain conformation may be essential for the production of a wide range of binding specificities. However, by constructing an antibody library based on a single known main-chain conformation it has been found, contrary to expectation, that diversity in the main-chain conformation is not required to generate sufficient diversity to target substantially all antigens. Even more surprisingly, the single main-chain conformation need not be a consensus structure - a single naturally occurring conformation can be used as the basis for an entire library. Thus, in a one particular aspect, the dAbs possess a single known main-chain conformation.

The single main-chain conformation that is chosen may be commonplace among molecules of the immunoglobulin superfamily type in question. A conformation is commonplace when a significant number of naturally occurring molecules are observed to adopt it. Accordingly, in one aspect, the natural occurrence of the different main-chain conformations for each binding loop of an immunoglobulin domain are considered separately and then a naturally occurring variable domain is chosen which possesses the desired combination of main-chain conformations for
the different loops. If none is available, the nearest equivalent may be chosen. The desired combination of main-chain conformations for the different loops may be created by selecting germline gene segments which encode the desired main-chain conformations. In one example, the selected germline gene segments are frequently expressed in nature, and in particular they may be the most frequently expressed of all natural germline gene segments.

In designing libraries the incidence of the different main-chain conformations for each of the six antigen binding loops may be considered separately. For H1, H2, L1, L2 and L3, a given conformation that is adopted by between 20% and 100% of the antigen binding loops of naturally occurring molecules is chosen. Typically, its observed incidence is above 35% (i.e. between 35% and 100%) and, ideally, above 50% or even above 65%. Since the vast majority of H3 loops do not have canonical structures, it is preferable to select a main-chain conformation which is commonplace among those loops which do display canonical structures. For each of the loops, the conformation which is observed most often in the natural repertoire is therefore selected. In human antibodies, the most popular canonical structures (CS) for each loop are as follows: H1 - CS 1 (79% of the expressed repertoire), H2 - CS 3 (46%), L1 - CS 2 of V\(_H\) (39%), L2 - CS 1 (100%), L3 - CS 1 of V\(_L\) (36%) (calculation assumes a \(\kappa:\lambda\) ratio of 70:30, Hood et al. (1967) Cold Spring Harbor Symp. Quant. Biol., 48: 133). For H3 loops that have canonical structures, a CDR3 length (Kabat et al. (1991) *Sequences of proteins of immunological interest*, U.S. Department of Health and Human Services) of seven residues with a salt-bridge from residue 94 to residue 101 appears to be the most common. There are at least 16 human antibody sequences in the EMBL data library with the required H3 length and key residues to form this conformation and at least two crystallographic structures in the protein data bank which can be used as a basis for antibody modelling (2cgr and 1tet). The most frequently expressed germline gene segments that this combination of canonical structures are the V\(_H\) segment 3-23 (DP-47), the J\(_H\) segment JH4b, the V\(_K\) segment 02/012 (DPK9) and the J\(_L\) segment J\(_K\) 1. V\(_H\) segments DP45 and DP38 are also suitable. These segments can therefore be used in combination as a basis to construct a library with the desired single main-chain conformation.

Alternatively, instead of choosing the single main-chain conformation based on the natural occurrence of the different main-chain conformations for each of the binding loops in isolation, the natural occurrence of combinations of main-chain conformations is used as the basis for choosing the single main-chain conformation. In the case of antibodies, for example, the natural occurrence of canonical structure combinations for any two, three, four, five, or for all six of the antigen binding loops can be determined. Here, the chosen conformation may be commonplace in naturally occurring antibodies and may be observed most frequently in the natural repertoire. Thus, in human antibodies, for example, when natural combinations of the five antigen binding loops, H1, H2, L1, L2 and L3, are considered, the most frequent
combination of canonical structures is determined and then combined with the most popular conformation for the H3 loop, as a basis for choosing the single main-chain conformation.

5 Diversification of the canonical sequence

Having selected several known main-chain conformations or a single known main-chain conformation, dAbs can be constructed by varying the binding site of the molecule in order to generate a repertoire with structural and/or functional diversity. This means that variants are generated such that they possess sufficient diversity in their structure and/or in their function so that they are capable of providing a range of activities.

The desired diversity is typically generated by varying the selected molecule at one or more positions. The positions to be changed can be chosen at random or they may be selected. The variation can then be achieved either by randomisation, during which the resident amino acid is replaced by any amino acid or analogue thereof, natural or synthetic, producing a very large number of variants or by replacing the resident amino acid with one or more of a defined subset of amino acids, producing a more limited number of variants.

20 Various methods have been reported for introducing such diversity. Error-prone PCR (Hawkins et al. (1992) J. Mol. Biol., 226: 889), chemical mutagenesis (Deng et al. (1994) J. Biol. Chem., 269: 9533) or bacterial mutator strains (Low et al. (1996) J. Mol. Biol., 260: 359) can be used to introduce random mutations into the genes that encode the molecule. Methods for mutating selected positions are also well known in the art and include the use of mismatched oligonucleotides or degenerate oligonucleotides, with or without the use of PCR. For example, several synthetic antibody libraries have been created by targeting mutations to the antigen binding loops. The H3 region of a human tetanus toxoid-binding Fab has been randomised to create a range of new binding specificities (Barbas et al. (1992) Proc. Natl. Acad. Sci. USA, 89: 4457). Random or semi-random H3 and L3 regions have been appended to germline V gene segments to produce large libraries with unmutated framework regions (Hoogenboom & Winter (1992) J. Mol. Biol., 227: 381; Barbas et al. (1992) Proc. Natl. Acad. Sci. USA, 89: 4457; Nissim et al. (1994) EMBO J., 13: 692; Griffiths et al. (1994) EMBO J., 13: 3245; De Kruijff et al. (1995) J. Mol. Biol., 248: 97). Such diversification has been extended to include some or all of the other antigen binding loops (Cramer et al. (1996) Nature Med., 2 : 100; Riechmann et al. (1995) Bio/Technology, 13: 475; Morphosys, WO97/08320, supra).

40 Since loop randomisation has the potential to create approximately more than 10^{15} structures for H3 alone and a similarly large number of variants for the other five loops, it is not feasible using current transformation technology or even by using cell free systems to produce a library representing all possible combinations. For
example, in one of the largest libraries constructed to date, \(6 \times 10^{10}\) different antibodies, which is only a fraction of the potential diversity for a library of this design, were generated (Griffiths et al. (1994) supra).

In one embodiment, only those residues which are directly involved in creating or modifying the desired function of the molecule are diversified. For many molecules, the function will be to bind a target and therefore diversity should be concentrated in the target binding site, while avoiding changing residues which are crucial to the overall packing of the molecule or to maintaining the chosen main-chain conformation.

In one aspect, libraries of dAbs are used in which only those residues in the antigen binding site are varied. These residues are extremely diverse in the human antibody repertoire and are known to make contacts in high-resolution antibody/antigen complexes. For example, in L2 it is known that positions 50 and 53 are diverse in naturally occurring antibodies and are observed to make contact with the antigen. In contrast, the conventional approach would have been to diversify all the residues in the corresponding Complementarity Determining Region (CDR1) as defined by Kabat et al. (1991, supra), some seven residues compared to the two diversified in the library. This represents a significant improvement in terms of the functional diversity required to create a range of antigen binding specificities.

In nature, antibody diversity is the result of two processes: somatic recombination of germline V, D and J gene segments to create a naive primary repertoire (so called germline and junctional diversity) and somatic hypermutation of the resulting rearranged V genes. Analysis of human antibody sequences has shown that diversity in the primary repertoire is focused at the centre of the antigen binding site whereas somatic hypermutation spreads diversity to regions at the periphery of the antigen binding site that are highly conserved in the primary repertoire (see Tomlinson et al. (1996) J. Mol. Biol., 256: 813). This complementarity has probably evolved as an efficient strategy for searching sequence space and, although apparently unique to antibodies, it can easily be applied to other polypeptide repertoires. The residues which are varied are a subset of those that form the binding site for the target. Different (including overlapping) subsets of residues in the target binding site are diversified at different stages during selection, if desired.

In the case of an antibody repertoire, an initial 'naive' repertoire is created where some, but not all, of the residues in the antigen binding site are diversified. As used herein in this context, the term "naive" or "dummy" refers to antibody molecules that have no pre-determined target. These molecules resemble those which are encoded by the immunoglobulin genes of an individual who has not undergone immune diversification, as is the case with fetal and newborn individuals, whose immune systems have not yet been challenged by a wide variety of antigenic stimuli. This
repertoire is then selected against a range of antigens or epitopes. If required, further
diversity can then be introduced outside the region diversified in the initial repertoire.
This matured repertoire can be selected for modified function, specificity or affinity.

It will be understood that the sequences described herein include sequences which
are substantially identical, for example sequences which are at least 90% identical,
for example which are at least 91%, or at least 92%, or at least 93%, or at least 94%
or at least 95%, or at least 96%, or at least 97% or at least 98%, or at least 99%
identical to the sequences described herein.

For nucleic acids, the term "substantial identity" indicates that two nucleic acids, or
designated sequences thereof, when optimally aligned and compared, are identical,
with appropriate nucleotide insertions or deletions, in at least about 80% of the
nucleotides, usually at least about 90% to 95%, and more preferably at least about
98% to 99.5% of the nucleotides. Alternatively, substantial identity exists when the
segments will hybridize under selective hybridization conditions, to the complement
of the strand.

For nucleotide and amino acid sequences, the term "identical" indicates the degree of
identity between two nucleic acid or amino acid sequences when optimally aligned
and compared with appropriate insertions or deletions. Alternatively, substantial
identity exists when the DNA segments will hybridize under selective hybridization
conditions, to the complement of the strand.

The percent identity between two sequences is a function of the number of identical
positions shared by the sequences (i.e., % identity = \# of identical positions/total \# of
positions times 100), taking into account the number of gaps, and the length of each
gap, which need to be introduced for optimal alignment of the two sequences. The
comparison of sequences and determination of percent identity between two
sequences can be accomplished using a mathematical algorithm, as described in the
non-limiting examples below.

The percent identity between two nucleotide sequences can be determined using the
GAP program in the GCG software package, using a NWSgapdna.CMP matrix and a
gap weight of 40, 50, 60, 70, or 80 and a length weight of 1, 2, 3, 4, 5, or 6. The
percent identity between two nucleotide or amino acid sequences can also be
determined using the algorithm of E. Meyers and W. Miller (Comput. Appl. Biosci.,
4:1 1-17 (1988)) which has been incorporated into the ALIGN program (version 2.0),
using a PAM120 weight residue table, a gap length penalty of 12 and a gap penalty
of 4. In addition, the percent identity between two amino acid sequences can be
determined using the Needleman and Wunsch (J. Mol. Biol. 48:444-453 (1970))
algorithm which has been incorporated into the GAP program in the GCG software
package, using either a Blossum 62 matrix or a PAM250 matrix, and a gap weight of
16, 14, 12, 10, 8, 6, or 4 and a length weight of 1, 2, 3, 4, 5, or 6.
By way of example, a polynucleotide sequence of the present invention may be identical to the reference sequence of SEQ ID NO: 122, that is be 100% identical, or it may include up to a certain integer number of nucleotide alterations as compared to the reference sequence. Such alterations are selected from the group consisting of at least one nucleotide deletion, substitution, including transition and transversion, or insertion, and wherein said alterations may occur at the 5’ or 3’ terminal positions of the reference nucleotide sequence or anywhere between those terminal positions, interspersed either individually among the nucleotides in the reference sequence or in one or more contiguous groups within the reference sequence. The number of nucleotide alterations is determined by multiplying the total number of nucleotides in SEQ ID NO: 122 by the numerical percent of the respective percent identity (divided by 100) and subtracting that product from said total number of nucleotides in SEQ ID NO: 122, or:

\[ n_n \leq x_n \cdot (x_n \cdot y), \]

wherein \( n_n \) is the number of nucleotide alterations, \( x_n \) is the total number of nucleotides in SEQ ID NO: 122, and \( y \) is 0.50 for 50%, 0.60 for 60%, 0.70 for 70%, 0.80 for 80%, 0.85 for 85%, 0.90 for 90%, 0.95 for 95%, 0.97 for 97% or 1.00 for 100%, and wherein any non-integer product of \( x_n \) and \( y \) is rounded down to the nearest integer prior to subtracting it from \( x_n \). Alterations of the polynucleotide sequence of SEQ ID NO: 122 may create nonsense, missense or frameshift mutations in this coding sequence and thereby alter the polypeptide encoded by the polynucleotide following such alterations.

Similarly, in another example, a polypeptide sequence of the present invention may be identical to the reference sequence encoded by SEQ ID NO: 26, that is be 100% identical, or it may include up to a certain integer number of amino acid alterations as compared to the reference sequence such that the % identity is less than 100%. Such alterations are selected from the group consisting of at least one amino acid deletion, substitution, including conservative and non-conservative substitution, or insertion, and wherein said alterations may occur at the amino- or carboxy-terminal positions of the reference polypeptide sequence or anywhere between those terminal positions, interspersed either individually among the amino acids in the reference sequence or in one or more contiguous groups within the reference sequence. The number of amino acid alterations for a given % identity is determined by multiplying the total number of amino acids in the polypeptide sequence encoded by SEQ ID NO: 26 by the numerical percent of the respective percent identity (divided by 100) and then subtracting that product from said total number of amino acids in the polypeptide sequence encoded by SEQ ID NO: 26, or:

\[ n_a \leq x_a \cdot (x_a \cdot y), \]

wherein \( n_a \) is the number of amino acid alterations, \( x_a \) is the total number of amino acids in the polypeptide sequence encoded by SEQ ID NO: 26, and \( y \) is, for instance 0.70 for 70%, 0.80 for 80%, 0.85 for 85% etc., and wherein any non-integer product of \( x_a \) and \( y \) is rounded down to the nearest integer prior to subtracting it from \( x_a \).
Examples

The following methods were used in the examples described herein.

Method 1
Binding to E.Coli-expressed recombinant human IL-13 by ELISA

mAbdAb molecules were assessed for binding to recombinant £co//-expressed human IL-13 in a direct binding ELISA. In brief, 5µg/ml recombinant £co//-expressed human IL-13 (made and purified at GSK) was coated to a 96-well ELISA plate. The wells were blocked for 1 hour at room temperature, mAbdAb constructs were then titrated out across the plate (usually from around 100nM in 3-fold dilutions to around 0.01 nM). Binding was detected using an appropriate dilution of anti-human kappa light chain peroxidase conjugated antibody (catalogue number A7164, Sigma-Aldrich) or an appropriate dilution of anti-human IgG γ chain specific peroxidase conjugated detection antibody (catalogue number A6029, Sigma-Aldrich).

Method 2
Binding to E.Coli-expressed recombinant human IL-4 by ELISA

mAbdAb constructs were assessed for binding to recombinant £co//-expressed human IL-4 in a direct binding ELISA. In brief, 5µg/ml recombinant £co//-expressed human IL-4 (made and purified at GSK) was coated to a 96-well ELISA plate. The wells were blocked for 1 hour at room temperature, mAbdAb constructs were then titrated out across the plate (usually from around 100nM in 3-fold dilutions to around 0.01 nM). Binding was detected using an appropriate dilution of goat anti-human kappa light chain peroxidase conjugated antibody (catalogue number A71 64, Sigma-Aldrich) or an appropriate dilution of anti-human IgG γ chain specific peroxidase conjugated detection antibody (catalogue number A6029, Sigma-Aldrich).

Method 3
Binding to E.Coli-expressed recombinant human IL-18 by ELISA

mAbdAb constructs were assessed for binding to recombinant £co//-expressed human IL-18 in a direct binding ELISA. In brief, 5µg/ml recombinant £co//-expressed human IL-18 (made and purified at GSK) was coated to a 96-well ELISA plate. The wells were blocked for 1 hour at room temperature, mAbdAb constructs were then titrated out across the plate (usually from around 100nM in 3-fold dilutions to around 0.01 nM). Binding was detected using a dilution of 1 in 2000 of anti-human kappa light chain peroxidase conjugated antibody (catalogue number A71 64, Sigma-Aldrich) or using a dilution of 1 in 2000 of anti-human IgG γ chain specific peroxidase conjugated detection antibody (catalogue number A6029, Sigma-Aldrich).
Method 4
Biacore™ binding affinity assessment for binding to E.Coli-expressed recombinant human IL-13

The binding affinity of mAbdAb constructs for recombinant E.Coli/-expressed human IL-13 were assessed by Biacore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufacturers recommendations. mAbdAb constructs were then captured onto this surface and human IL-13 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions (such as 100mM phosphoric acid), this did not significantly affect the ability to capture antibody for a subsequent IL-13 binding event. The anti-human IgG surface was regenerated either using similar conditions to the Protein A surface or by using 3M MgCl₂. The work was carried out on the Biacore™ 3000 and/or the T 100 machine, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. Biacore™ runs were carried out at 25°C or 37°C.

Method 5
Biacore™ binding affinity assessment for binding to E.Coli-expressed recombinant human IL-4

The binding affinity of mAbdAb constructs for recombinant E.Coli/-expressed human IL-4 were assessed by Biacore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufacturers recommendations. mAbdAb constructs were then captured onto this surface and human IL-4 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions (such as 100mM phosphoric acid), this did not significantly affect the ability to capture antibody for a subsequent IL-4 binding event. The anti-human IgG surface was regenerated either using similar conditions to the Protein A surface or by using 3M MgCl₂. The work was carried out on Biacore™ 3000 and/or the T 100 and/or the A 100 machine, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. Biacore™ runs were carried out at 25°C or 37°C.

Method 6
Biacore™ binding affinity assessment for binding to E.Coli-expressed recombinant human IL-18
The binding affinity of mAbdAb constructs for recombinant E. Co//-expressed human IL-18 was assessed by Biacore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufactures recommendations. mAbdAb constructs were then captured onto this surface and human IL-18 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions (such as 10OmM phosphoric acid), this did not significantly affect the ability to capture antibody for a subsequent IL-18 binding event. The anti-human IgG surface was regenerated either using similar conditions to the Protein A surface or by using 3M MgCl₂. The work was carried out on Biacore™ 3000 and / or the T100 and / or the A100 machine, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. The Biacore™ run was carried out at 25°C.

Method 7
Stoichiometry assessment of mAbdAb bispecific antibodies or trispecific antibody for IL-13, IL-4 or IL-18 (using Biacore™)

Anti-human IgG was immobilised onto a CM5 biosensor chip by primary amine coupling. mAbdAb constructs were captured onto this surface after which a single concentration of IL-13, IL-4 or IL-18 cytokine was passed over, this concentration was enough to saturate the binding surface and the binding signal observed reached full R-max. Stoichiometries were then calculated using the given formula:

\[ \text{Stoich} = \frac{\text{Rmax} \times \text{Mw (ligand)}}{\text{Mw (analyte)}} \times \text{R (ligand immobilised or captured)} \]

Where the stoichiometries were calculated for more than one analyte binding at the same time, the different cytokines were passed over sequentially at the saturating cytokine concentration and the stoichiometries calculated as above. The work was carried out on the Biacore 3000, at 25°C using HBS-EP running buffer.

Method 8
Neutralisation of E.Coli-expressed recombinant human IL-13 in a TF-1 cell proliferation bioassay

TF-1 cells proliferate in response to a number of different cytokines including human IL-13. The proliferative response of these cells for IL-13 can therefore be used to measure the bioactivity of IL-13 and subsequently an assay has been developed to determine the IL-13 neutralisation potency (inhibition of IL-13 bioactivity) of mAbdAb constructs.
The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. Approximately 14ng/ml recombinant E.Coli-expressed human IL-13 was pre-incubated with various dilutions of mAbdAb constructs (usually from 200nM titrated in 3-fold dilutions to 0.02nM) in a total volume of 50µl for 1 hour at 37°C. These samples were then added to 50µl of TF-1 cells (at a concentration of 2x10^5 cells per ml) in a sterile 96-well tissue culture plate. Thus the final 100µl assay volume contained various dilutions of mAbdAb constructs (at a final concentration of 100nM titrated in 3-fold dilutions to 0.01 nM), recombinant E.Coli-expressed human IL-13 (at a final concentration of 7ng/ml) and TF-1 cells (at a final concentration of 1x10^5 cells per ml). The assay plate was incubated at 37°C for approximately 3 days in a humidified CO₂ incubator. The amount of cell proliferation was then determined using the 'CellTitre 96® Non-Radioactive Cell Proliferation Assay' from Promega (catalogue number G4100), as described in the manufacturers instructions. The absorbance of the samples in the 96-well plate was read in a plate reader at 570nm.

The capacity of the mAbdAb constructs to neutralise recombinant E.Coli-expressed human IL-13 bioactivity was expressed as that concentration of the mAbdAb construct required to neutralise the bioactivity of the defined amount of human IL-13 (7ng/ml) by 50% (= ND₅₀). The lower the concentration of the mAbdAb construct required, the more potent the neutralisation capacity. The ND₅₀ data provided herein were calculated manually or by using the Robosage software package which is inherent within microsoft excel.

Method 9

Neutralisation of E.Coli-expressed recombinant human IL-4 in a TF-1 cell proliferation bioassay

TF-1 cells proliferate in response to a number of different cytokines including human IL-4. The proliferative response of these cells for IL-4 can therefore be used to measure the bioactivity of IL-4 and subsequently an assay has been developed to determine the IL-4 neutralisation potency (inhibition of IL-4 bioactivity) of mAbdAb constructs.

The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. Approximately 2.2ng/ml recombinant E.Coli-expressed human IL-4 was pre-incubated with various dilutions of mAbdAb constructs (usually from 200nM titrated in 3-fold dilutions to 0.02nM) in a total volume of 50µl for 1 hour at 37°C. These samples were then added to 50µl of TF-1 cells (at a concentration of 2x10^5 cells per ml) in a sterile 96-well tissue culture plate. Thus the final 100µl assay volume contained various dilutions of mAbdAb constructs (at a final concentration of 100nM titrated in 3-fold dilutions to 0.01 nM), recombinant E.Coli-expressed human IL-4 (at a final concentration of 1.1 ng/ml) and
TF-1 cells (at a final concentration of 1x10^5 cells per ml). The assay plate was incubated at 37°C for approximately 3 days in a humidified CO₂ incubator. The amount of cell proliferation was then determined using the 'CellTitre 96® Non-Radioactive Cell Proliferation Assay' from Promega (catalogue number G4100), as described in the manufacturers instructions. The absorbance of the samples in the 96-well plate was read in a plate reader at 570nm.

The capacity of the mAbdAb constructs to neutralise recombinant E.Coli-expressed human IL-4 bioactivity was expressed as that concentration of the mAbdAb construct required to neutralise the bioactivity of the defined amount of human IL-4 (1.1 ng/ml) by 50% (ND₅₀). The lower the concentration of the mAbdAb construct required, the more potent the neutralisation capacity. The ND₅₀ data provided herein were calculated manually or by using the Robosage software package which is inherent within microsoft excel.

Method 10
Dual neutralisation of E.Coli-expressed recombinant human IL-13 and E.Coli-expressed recombinant human IL-4 in a TF-1 cell proliferation bioassay

TF-1 cells proliferate in response to a number of different cytokines including human IL-13 and human IL-4. The proliferative response of these cells for IL-13 and IL-4 can therefore be used to measure the bioactivity of IL-13 and IL-4 simultaneously and subsequently an assay has been developed to determine the dual IL-13 and IL-4 neutralisation potency (dual inhibition of IL-13 and IL-4 bioactivity) of mAbdAb constructs.

The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. Approximately 14ng/ml recombinant E.Coli-expressed human IL-13 and approximately 2.2ng/ml recombinant E.Coli-expressed human IL-4 were pre-incubated with various dilutions of mAbdAb constructs (usually from 200nM titrated in 3-fold dilutions to 0.02nM) in a total volume of 50µl for 1 hour at 37°C. These samples were then added to 50µl of TF-1 cells (at a concentration of 2x10^5 cells per ml) in a sterile 96-well tissue culture plate. Thus the final 100µl assay volume, contained various dilutions of mAbdAb constructs (at a final concentration of 100nM titrated in 3-fold dilutions to 0.01 nM), recombinant E.Coli-expressed human IL-13 (at a final concentration of 7ng/ml), recombinant E.Coli-expressed human IL-4 (at a final concentration of 1.1ng/ml) and TF-1 cells (at a final concentration of 1x10^5 cells per ml). The assay plate was incubated at 37°C for approximately 3 days in a humidified CO₂ incubator. The amount of cell proliferation was then determined using the 'CellTitre 96® Non-Radioactive Cell Proliferation Assay' from Promega (catalogue number G4100), as described in the manufacturers instructions. The absorbance of the samples in the 96-well plate was read in a plate reader at 570nm.
**Method 11**

**Biacore™ binding affinity assessment for binding to Sf27-expressed recombinant human IL-5**

The binding affinity of mAbdAb molecules for recombinant Sf27/-expressed human IL-5 was assessed by Biacore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufactures recommendations. mAbdAb molecules were then captured onto this surface and human IL-5 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions (such as 100mM phosphoric acid), this did not significantly affect the ability to capture antibody for a subsequent IL-5 binding event. The anti-human IgG surface was regenerated either using similar conditions to the Protein A surface or by using 3M MgCl₂ The work was carried out on Biacore™ 3000, T100 and A100 machines, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. The Biacore™ run was carried out at 25°C.

**Method 12**

**VEGF Receptor Binding Assay.**
This assay measures the binding of VEGF₁₆₅ to VEGF R2 (VEGF receptor) and the ability of test molecules to block this interaction. ELISA plates were coated overnight with VEGF receptor (R&D Systems, Cat No: 357-KD-050) (0.5µg/ml final concentration in 0.2M sodium carbonate bicarbonate pH9.4), washed and blocked with 2% BSA in PBS. VEGF (R&D Systems, Cat No: 293-VE-050) and the test molecules (diluted in 0.1%BSA in 0.05% Tween 20™ PBS) were pre-incubated for one hour prior to addition to the plate (3ng/ml VEGF final concentration). Binding of VEGF to VEGF receptor was detected using biotinylated anti-VEGF antibody (0.5µg/ml final concentration) (R&D Systems, Cat No: BAF293) and a peroxidase conjugated anti-biotin secondary antibody (1:5000 dilution) (Stratech, Cat No: 200-032-096) and visualised at OD450 using a colorimetric substrate (Sure Blue TMB peroxidase substrate, KPL) after stopping the reaction with an equal volume of 1M HCl.

**Method 13**

**EGFR Kinase Assay**
Activation of EGFR expressed on the surface of A431 cells through its interaction with EGF leads to tyrosine kinase phosphorylation of the receptor. Reduction of EGFR tyrosine kinase phosphorylation was measured to determine potency of test molecules. A431 cells were allowed to adhere to 96 well tissue culture plates overnight then the test molecule was added and left for 1 hour and then incubated for 10 min with EGF (at 300ng/ml) (R&D Systems catalogue number 236-EG). The cells
were lysed and the lysed preparation transferred to ELISA plates coated with anti-EGFR antibody (at 1ug/ml) (R&D Systems, cat # AF231). Both phosphorylated and non-phosphorylated EGFR present in the lysed cell solution was captured. After washing away unbound material phosphorylated EGFR was specifically detected using a HRP conjugated anti-phosphotyrosine antibody (1:2000 dilution) (Upstate Biotechnology, cat # 16-105). Binding was visualised using a colorimetric substrate.

**Method 14**

**MRC-5/TNF Assay**

The ability of test molecules to prevent human TNF-a binding to human TNFR1 and neutralise IL-8 secretion was determined using human lung fibroblast MRC-5 cells. A dilution series of test samples was incubated with TNF-a (500pg/ml) (Peprotech) for 1 hour. This was then diluted 1 in 2 with a suspension of MRC-5 cells (ATCC, Cat.# CCL-171) (5x10^3 cells/well). After an overnight incubation, samples were diluted 1 in 10, and IL-8 release was determined using an IL-8 ABI 8200 cellular detection assay (FMAT) where the IL-8 concentration was determined using anti-IL-8 (R&D systems, Cat# 208-IL) coated polystyrene beads, biotinylated anti-IL-8 (R&D systems, Cat# BAF208) and streptavidin Alexafluor 647 (Molecular Probes, Cat#S32357). The assay readout was localised fluorescence emission at 647nm and unknown IL-8 concentrations were interpolated using an IL-8 standard curve included in the assay.

**Method 15**

**MRC-5/IL-1 Assay**

The ability of test molecules to prevent human IL-1a binding to human IL1-R and neutralise IL-8 secretion was determined using human lung fibroblast MRC-5 cells. MRC-5 cells (ATCC, Cat.# CCL-171) were trypsinised then incubated with the test samples for one hour as a suspension. IL-1a (200pg/ml final concentration) (R&D Systems cat no: 200-LA) was then added. After an overnight incubation IL-8 release was determined using an IL-8 quantification ELISA kit (R&D Systems) with anti-IL-8 coated ELISA plates, biotinylated anti-IL-8 and streptavidin-HRP. The assay readout is colourimetric absorbance at 450nm and unknown IL-8 concentrations are interpolated using an IL-8 standard curve included in the assay.

**Method 16**

**Neutralisation potency of E.Coli-expressed recombinant human IL-13 or IL-4 in a whole blood phospho-STAT6 bioassay**

Whole blood cells can be stimulated ex-vivo with recombinant E.Coli-expressed human IL-4 (rhlL-14) or IL-13 (rhlL-13) to express phospho STAT6 (pSTAT6). This assay was developed to quantitatively measure pSTAT6 and consequently determine the neutralisation potency (inhibition of IL-4 or IL-13 bioactivity) of mAbdAb constructs.
The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. 12ng/ml of rhIL-13 or rhIL-4 was prepared in serum free cell culture medium and 31.2µl added to wells of a 96-well plate. A 9 point dilution curve of mAbdAb constructs or isotype control was prepared at 6x the final assay concentration and 31.2µl of each dilution added to wells containing either rhIL-4 or rhIL-13. 125µl of heparinized human whole blood was added to all wells and mixed on a shaker for 30 seconds. The final assay volume contained various dilutions of mAbdAb constructs together with rhIL-13 or rhIL-4 at a final concentration of 2ng/ml. The assay plate was incubated at 37°C, 5%CC>2 for 60 minutes.

The cells were then lysed by the addition of 62.5µl of 4x lysis buffer. The lysis buffer contained final assay concentrations of 50mM Tris hydrochloride, 300mM sodium chloride, 1% NP40, 0.5% sodium deoxycholate, 50mM sodium fluoride, 1mM sodium orthovanadate, 1mM EDTA, and protease inhibitor cocktail. The plates were placed on ice for 30 minutes then frozen at -80°C until assayed for pSTAT6.

The measurement of pSTAT6 in the whole blood samples was performed using an electro-chemiluminescent immuno-assay (Meso-Scale-Discovery, MSD). In brief, avidin coated 96-well MSD plates were blocked with 150µL per well of 5% MSD blocker A for 1 hour at room temperature on a shaker at 750rpm. The plate was washed 3 times with 150µl per well of MSD Tris wash buffer. 25µl per well of capture antibody (biotinylated mouse anti-human STAT6 monoclonal antibody) was added and the plates incubated overnight at 4°C. The capture antibody had been diluted to 4µg/ml in assay buffer consisting of 50mM Tris, 150mM sodium chloride, 0.2% BSA, 0.5% Tween 20, 1mM EDTA. The plate was washed 3 times with MSD tris wash buffer then blocked with 150µl of 5% MSD blocker A for 1 hour at room temperature on a shaker. Plates were washed 3 times as stated previously, then 25µl of whole blood lysate or pSTAT6 calibrator added per well. Plates were incubated for 3 hours at room temperature on a shaker. Plates were washed 3 times then 25µl of rabbit anti human pSTAT6 antibody (diluted 1 in 800 in assay buffer) was added and then incubated for 1 hour at room temperature. After further washing, 25µl per well of a 1 in 500 dilution of MSD TAG goat anti-rabbit IgG antibody was added and then incubated for 1 hour at room temperature on a shaker. Plates were washed again before addition of 150µl per well of 2x MSD read buffer T. Plates were read immediately on a MSD SECTOR imager.

The ability of the mAbdAb constructs to neutralise rhIL-13 or rhIL-4 bioactivity was expressed as the concentration of the mAbdAb construct required to neutralise 2ng/ml of human IL-4 or human IL-13 by 50% (IC50). The lower the concentration of the mAbdAb construct required, the more potent the neutralisation capacity.

**Method 17**
Binding to E.Coli-expressed recombinant cynomolqus IL-13 by ELISA

mAbdAb molecules were assessed for binding to recombinant £.co//-expressed cynomolqus IL-13 in a direct binding ELISA. In brief, 5µg/ml recombinant £.coliexpressed cynomolqus IL-13 (made and purified at GSK) was coated to a 96-well ELISA plate. The wells were blocked for 1 hour at room temperature, mAbdAb molecules were then titrated out across the plate (usually from around 100nM in 3-fold dilutions to around 0.01 nM). Binding was detected using an appropriate dilution of anti-human kappa light chain peroxidase conjugated antibody (catalogue number A7164, Sigma-Aldrich) or an appropriate dilution of anti-human IgG γ chain specific peroxidase conjugated detection antibody (catalogue number A6029, Sigma-Aldrich).

Method 18
Not used

Method 19
Inhibition of human IL-4 binding to human IL4 receptor alpha (IL4Rα) by ELISA

Unless otherwise stated all reagents were diluted to the required concentration in block solution (4% bovine serum albumin in tris-buffered saline and 0.05% Tween20) just prior to use. An ELISA plate was coated over-night at 4°C with 5µg/ml of recombinant human IL4Rα-Fc chimaera (R&D Systems, Cat. No. 604-4R) in phosphate buffered saline. All subsequent steps were carried out at room temperature. The plate was blocked for 2 hours in block solution before addition of 50µl of various concentrations of mAbdAb (or the positive control mAbs or dAbs) which had been pre-mixed with 0.02µg/ml of recombinant human IL-4 (made at GSK). Plates were incubated for 1 hour before washing 4 times in wash buffer (Tris buffered saline and 0.05% Tween20). 50µl of a 0.5µg/ml solution of biotinylated anti-human IL-4 (R&D Systems, Cat. No. BAF 204) was added to each well and incubated for 1 hour. The plate was washed x4 in wash buffer before addition of 50µl/well of a 1/2000 dilution of Extravadin (Sigma, Cat. No. E2886). After one hour the plate was washed 4 times and a colourimetric signal was detected by incubating with OPD peroxidase substrate (from Sigma), the reaction was stopped with the stop solution (3M H₂SO₄ acid) and absorbance data obtained by reading on a plate-reader at 490nm. Mean absorbance and standard error was plotted in GraphPad Prism and IC₅₀ values were calculated using Cambridge Soft BioAssay.

Method 20
Neutralisation of E.Coli-expressed recombinant cynomolqus IL-13 in a TF-1 cell proliferation bioassay

TF-1 cells proliferate in response to a number of different cytokines including cynomolqus IL-13. The proliferative response of these cells for IL-13 can therefore be
used to measure the bioactivity of IL-13 and subsequently an assay has been developed to determine the IL-13 neutralisation potency (inhibition of IL-13 bioactivity) of mAbdAb constructs.

The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. Approximately 14ng/ml recombinant E.Coli-expressed cynomolgus IL-13 was pre-incubated with various dilutions of mAbdAb constructs (usually from 100OnM or 20OnM titrated in 3-fold dilutions to 1nM or 0.02nM) in a total volume of 50µl for 1 hour at 37°C. These samples were then added to 50µl of TF-1 cells (at a concentration of 2x10^5 cells per ml) in a sterile 96-well tissue culture plate. Thus the final 100µl assay volume contained various dilutions of mAbdAb constructs (at a final concentration of 50OnM or 100nM titrated in 3-fold dilutions to 0.5nM or 0.01 nM), recombinant E.Coli-expressed cynomolgus IL-13 (at a final concentration of 7ng/ml) and TF-1 cells (at a final concentration of 1x10^5 cells per ml). The assay plate was incubated at 37°C for approximately 3 days in a humidified CO₂ incubator. The amount of cell proliferation was then determined using the 'CellTitre 96® Non-Radioactive Cell Proliferation Assay' from Promega (catalogue number G4100), as described in the manufacturers instructions. The absorbance of the samples in the 96-well plate was read in a plate reader at 570nm.

The capacity of the mAbdAb constructs to neutralise recombinant E.Coli-expressed cynomolgus IL-13 bioactivity was expressed as that concentration of the mAbdAb construct required to neutralise the bioactivity of the defined amount of cynomolgus IL-13 (7ng/ml) by 50% (= ND₅₀). The lower the concentration of the mAbdAb construct required, the more potent the neutralisation capacity. The ND₅₀ data provided herein were calculated manually or by using the Robosage software package which is inherent within microsoft excel.

**Method 21**

Neutralisation of E.Coli-expressed recombinant cynomolgus IL-4 in a TF-1 cell proliferation bioassay

TF-1 cells proliferate in response to a number of different cytokines including cynomolgus IL-4. The proliferative response of these cells for IL-4 can therefore be used to measure the bioactivity of IL-4 and subsequently an assay has been developed to determine the IL-4 neutralisation potency (inhibition of IL-4 bioactivity) of mAbdAb constructs.

The assay was performed in sterile 96-well tissue culture plates under sterile conditions and all test wells were performed in triplicate. Approximately 2.2ng/ml recombinant E.Coli-expressed cynomolgus IL-4 was pre-incubated with various dilutions of mAbdAb constructs (usually from 20OnM titrated in 3-fold dilutions to
0.02nM) in a total volume of 50µl for 1 hour at 37°C. These samples were then added to 50µl of TF-1 cells (at a concentration of 2x10^5 cells per ml) in a sterile 96-well tissue culture plate. Thus the final 100µl assay volume contained various dilutions of mAbdAb constructs (at a final concentration of 100nM titrated in 3-fold dilutions to 0.01 nM), recombinant E.Coli-expressed cynomolagus IL-4 (at a final concentration of 1.1ng/ml) and TF-1 cells (at a final concentration of 1x10^5 cells per ml). The assay plate was incubated at 37°C for approximately 3 days in a humidified CO2 incubator. The amount of cell proliferation was then determined using the 'CellTitre 96® Non-Radioactive Cell Proliferation Assay' from Promega (catalogue number G4100), as described in the manufacturers instructions. The absorbance of the samples in the 96-well plate was read in a plate reader at 570nm.

The capacity of the mAbdAb constructs to neutralise recombinant E.Coli-expressed cynomolagus IL-4 bioactivity was expressed as that concentration of the mAbdAb construct required to neutralise the bioactivity of the defined amount of cynomolagus IL-4 (1.1ng/ml) by 50% (= ND_{50}). The lower the concentration of the mAbdAb construct required, the more potent the neutralisation capacity. The ND_{50} data provided herein were calculated manually or by using the Robosage software package which is inherent within microsoft excel.

**Method 22**

**Inhibition of human IL-13 binding to human IL13 receptor alpha 2 (IL13Rα2) by ELISA**

Unless otherwise stated all reagents were diluted to the required concentration in block solution (1% bovine serum albumin in tris-buffered saline and 0.05% Tween20) just prior to use. An ELISA plate was coated overnight at 4°C with 5µg/ml of recombinant human IL13Rα2/Fc chimera expressed in Sf21 cells (R&D Systems, Cat. No. 614-IR) in a solution of coating buffer (0.05M bicarbonate pH9.6, Sigma C-3041). The plate was blocked for 1 hour at room temperature in block solution (1% BSA in TBST) before addition of various concentrations of mAbdAb (or the positive control mAbs or dAbs) which had been pre-incubated with 30ng/ml of recombinant human IL-13 (made at GSK) for 30 mins at 37°C. Plates were incubated for 1 hour at room temperature before washing 3 times in wash buffer (Tris buffered saline and 0.05% Tween20). 50µl of a 0.5µg/ml solution of biotinylated anti-human IL-13 (R&D Systems, Cat. No. BAF 213) was added to each well and incubated for 1 hour at room temperature. The plate was washed three times in wash buffer before addition of an appropriate dilution of Extravadin (Sigma, Cat. No. E2886). After one hour the plate was washed and a colourimetric signal was detected by incubating with OPD peroxidase substrate (from Sigma), the reaction was stopped with the stop solution (3M acid) and absorbance data obtained by reading on a plate-reader at 490nm. Mean absorbance and standard error was plotted in Excel sheet and IC_{50} values were calculated using the Robosage software from Microsoft Excel.
Method 23

Biacore™ binding affinity assessment for binding to E.Coli-expressed recombinant cynomolgus IL-13

The binding affinity of mAbdAb (or mAb) molecules for recombinant E.Coli/-expressed cynomolgus IL-13 was assessed by Biacore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufactures recommendations. mAbdAb (or mAb) molecules were then captured onto this surface and cynomolgus IL-13 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions, this did not significantly affect the ability to capture antibody for a subsequent IL-13 binding event. The work was carried out on BIAcore™ 3000 and / or the T100 machine, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. BIAcore™ runs were carried out at 25°C or 37°C.

Method 24

BIAcore™ binding affinity assessment for binding to E.Coli-expressed recombinant cynomolgus IL-4

The binding affinity of mAbdAb (or mAb) molecules for recombinant E.Coli-expressed cynomolgus IL-4 were assessed by BIAcore™ analysis. Analyses were carried out using Protein A or anti-human IgG capture. Briefly, Protein A or anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufactures recommendations. mAbdAb (or mAb) molecules were then captured onto this surface and cynomolgus IL-4 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Protein A surface using mild acid elution conditions (such as 100mM phosphoric acid), this did not significantly affect the ability to capture antibody for a subsequent IL-4 binding event. The anti-human IgG surface was regenerated either using similar conditions to the Protein A surface or by using 3M MgCl₂. The work was carried out on BIAcore™ 3000 and / or the T100 and / or the A100 machine, data were analysed using the evaluation software in the machines and fitted to the 1:1 model of binding. BIAcore™ runs were carried out at 25°C or 37°C.

Method 25

IL-13 cell-based neutralisation assay

The potency of mAbdAbs having specificity for IL13 was assayed in an IL-13 cell assay using the engineered reporter cell line HEK Blue-STAT6. The transcription factor STAT6 is activated primarily by two cytokines with overlapping biologic functions, IL-4 and IL-13 which bind a receptor complex
composed of the IL-4Ralpha and IL-13Ralpha1. Upon ligand binding, the receptor complex activates the receptor-associated Janus kinases (JAK1 and Tyk2) leading to the recruitment of STAT6 and its phosphorylation. Activated STAT6 forms a homodimer that translocates to the nucleus, inducing transcription of genes under the control of the responsive promoter. The HEK Blue-STAT6 line is engineered to express Secreted Embryonic Alkaline Phosphatase (SEAP) under the control of such a promoter. Cells were plated into 96 well plates and incubated for 20-24 hours with pre-equilibrated human human IL-13 and test molecules. After this incubation period, the amount of SEAP produced by the cells as a result of IL-13 stimulation was then measured using the Quanti-blue system (Invivogen).
Example 1

1. Generation of dual targeting mAbdAbs

The dual targeting mAbdAbs set out in Tables 1-4 were constructed in the following way. Expression constructs were generated by grafting a sequence encoding a domain antibody on to a sequence encoding a heavy chain or a light chain (or both) of a monoclonal antibody such that when expressed the dAb is attached to the C-terminus of the heavy or light chain. For some constructs, linker sequences were used to join the domain antibody to heavy chain CH3 or light chain CK. In other constructs the domain antibody is joined directly to the heavy or light chain with no linker sequence. A general schematic diagram of these mAbdAb constructs is shown in Figure 8 (the mAb heavy chain is drawn in grey; the mAb light chain is drawn in white; the dAb is drawn in black).

An example of mAbdAb type 1 as set out in Figure 8 would be PascoH-G4S-474. An example of mAbdAb type 2 as set out in Figure 8 would be PascoL-G4S-474. An example of mAbdAb type 3 as set out in Figure 8 would be PascoHL-G4S-474. mAbdAb types 1 and 2 are tetravalent constructs, mAbdAb type 3 is a hexavalent construct.

A schematic diagram illustrating the construction of a mAbdAb heavy chain (top illustration) or a mAbdAb light chain (bottom illustration) is shown below. Unless otherwise stated, these restriction sites were used to construct the mAbdAbs described in Tables 1-4.

Note that for the heavy chain the term $V_H$ is the monoclonal antibody variable heavy chain sequence; ‘CH1, CH2 and CH3’ are human IgGl heavy chain constant region sequences; ‘linker’ is the sequence of the specific linker region used; ‘dAb’ is the domain antibody sequence. For the light chain the term $V_L$ is the monoclonal...
antibody variable light chain sequence; 'CK' is the human light chain constant region sequence; 'linker' is the sequence of the specific linker region used; 'dAb' is the domain antibody sequence.

Some DNA expression constructs were made de novo by oligo build. And other DNA expression constructs were derived from existing constructs (which were made as described above) by restriction cloning or site-directed mutagenesis.

These constructs (mAbdAb heavy or light chains) were cloned into mammalian expression vectors (RIn, RId or pTT vector series) using standard molecular biology techniques. A mammalian amino acid signal sequence (as shown in SEQ ID NO: 64) was used in the construction of these constructs.

For expression of mAbdAbs where the dAb is joined to the C-terminal end of the heavy chain of the monoclonal antibody, the appropriate heavy chain mAbdAb expression vector was paired with the appropriate light chain expression vector for that monoclonal antibody. For expression of mAbdAbs where the dAb is joined to the C-terminal end of the light chain of the monoclonal antibody, the appropriate light chain mAbdAb expression vector was paired with the appropriate heavy chain expression vector for that monoclonal antibody.

For expression of mAbdAbs where the dAb is joined to the C-terminal end of the heavy chain of the monoclonal antibody and where the dAb is joined to the C-terminal end of the light chain of the monoclonal antibody, the appropriate heavy chain mAbdAb expression vector was paired with the appropriate light chain mAbdAb expression vector.

1.1 Nomenclature and abbreviations used
Monoclonal antibody (mAb)
Monoclonal antibodies (mAbs)
Domain antibody (dAb)
Domain antibodies (dAbs)
Heavy Chain (H chain)
Light chain (L chain)
Heavy chain variable region (V_H)
Light chain variable region (V_L)
Human IgGI constant heavy region 1 (CH1)
Human IgGI constant heavy region 2 (CH2)
Human IgGI constant heavy region 3 (CH3)
Human kappa light chain constant region (CK)

1.2 Anti-IL13mAb-anti-IL4dAbs
Bispecific anti-IL13mAb-anti-IL4dAbs were constructed by as described above. A number of different linkers were used to join the anti-IL4 domain antibodies to the monoclonal antibody. Some constructs had no linker.

Note that a BamHI cloning site (which codes for amino acid residues G and S) was used to clone the linkers and dAbs either to CH3 of the mAb heavy chain or to CK of the mAb light chain. Thus in addition to the given linker sequence, additional G and S amino acid residues are present between the linker sequence and the domain antibody for both heavy chain and light chain expression constructs or between CH3 and the linker sequence in some but not all heavy chain expression constructs. However, when the G4S linker was placed between the mAb and dAb in the mAbdAb format, the BamHI cloning site was already present (due to the G and S amino acid residues inherent within the G4S linker sequence) and thus additional G and S amino acid residues were not present between CH3 or CK and the domain antibody in the constructs using this linker. When no linker sequence was between used in the mAb and dAb in the mAbdAb format, the BamHI cloning site (and hence the G and S amino acid residues) was still present between CH3 or CK and the domain antibody. Full details on the amino acid sequences of mAbdAb heavy and light chains are set out in Table 1.

Several of the following examples use an IL-4 mAb as a control antibody. The control IL-4 mAb used in these examples will either be the antibody having the heavy chain sequence of SEQ ID NO: 14 and the light chain sequence of SEQ ID NO: 15, or will be the antibody having the heavy chain sequence of SEQ ID NO: 166 and the light chain sequence of SEQ ID NO: 15. Both of these IL-4 mAbs share the same CDRs, and are expected to bind in the same way hence both of these antibodies are referred to as 'Pascolizumab' or 'IL-4 mAb' in the following examples.

Several of the following examples use an IL-5 mAb as a control antibody. The control IL-5 mAb used in these examples will either be the antibody having the heavy chain sequence of SEQ ID NO: 65 and the light chain sequence of SEQ ID NO: 66, or the antibody having the heavy chain sequence of SEQ ID NO: 191 and the light chain sequence of SEQ ID NO: 66. Both of these IL-5 antibodies share the same CDRs, and are expected to bind in the same way hence both of these antibodies are referred to as 'Mepolizumab' or 'IL-5 mAb' in the following examples.

The mAbdAbs set out in table 1 were expressed transiently in CHOK1 cell supernatants. Following mAbdAb quantification these mAbdAb containing supernatants were analysed for activity in IL-13 and IL-4 binding ELISAs.

### 1.5 Expression and purification of mAbdAbs

The mAbdAb expression constructs described in Example 1 were transfected into one or more of CHOK1 cells, CHOElα cells or HEK293-6E cells, expressed at small (approximately 3mls) or medium (approximately 50mls to 100mls) or large (approximately 1 litre) scale and then some of the constructs were purified using immobilised Protein A columns and quantified by reading absorbance at 280nm.

### 1.6 Size exclusion chromatography analyses of purified mAbdAbs

A number of mAbdAbs were analysed by size exclusion chromatography (SEC) and sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS PAGE). Representative data for some of these molecules (PascoH-G4S-474, PascoL-G4S-474, PascoH-474 and PascoHL-G4S-474) are shown in Figures 9, 10, 11 and 12 respectively. Representative data showing SEC and SDS Page analysis for these molecules with the 'GS' motif removed are shown in Figures 90-98.

In some cases SEC was used to further purify these molecules to remove aggregates.

### Example 2

**Binding of mAbdAbs to human IL-13 and human IL-4 by ELISA**

#### 2.1 Binding of anti-IL13mAb-anti-IL4dAbs to IL-13 and IL-4

mAbdAb supernatants, were tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 13.
Figure 13 shows that all of these anti-IL13mAb-anti-IL4dAbs bound IL-13. The binding activity of these mAbdAbs was also approximately equivalent (within 2-fold to 3-fold) to purified anti-human IL13 mAb alone, which was included in this assay as a positive control for IL-13 binding and in order to directly compare to the mAbdAbs. Purified anti-human IL4 mAb (Pascolizumab) was included as a negative control for IL-13 binding.

These molecules were also tested for binding to human IL-4 in a direct binding ELISA (as described in method 2). These data are shown in Figure 14. Figure 14 shows that all of these anti-IL13mAb-anti-IL4dAbs bound IL-4, but some variation in IL-4 binding activity was observed. No binding to IL-4 was observed when no anti-IL4 dAb was present in the mAbdAb construct. Purified anti-human IL13 mAb was also included as a negative control for binding to IL-4. Note that the anti-IL-4 dAbs alone were not tested in this assay as the dAbs are not detected by the secondary detection antibody; instead, purified anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay.

Purified samples of mAbdAbs, were also tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 15. These purified anti-IL13mAb-anti-IL4dAbs bound IL-13. The binding activity of these mAbdAbs for IL-13 was equivalent to that of purified anti-human IL13 mAb alone. An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-13 in this assay.

These purified mAbdAbs were also tested for binding to human IL-4 in a direct binding ELISA (as described in method 2). These data are shown in Figure 16. All of these anti-IL13mAb-anti-IL4dAbs bound IL-4. Note that the anti-IL-4 dAbs alone were not tested in this assay as the dAbs are not detected by the secondary detection antibody; instead, purified anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay. An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-4 in this assay.

2.2 Binding of anti-IL4mAb-anti-IL13dAbs to IL-13 and IL-4
mAbdAb supernatants were tested for binding to human IL-4 in a direct binding ELISA (as described in method 2). These data are shown in Figure 17 (some samples were prepared and tested in duplicate and this has been annotated as sample 1 and sample 2).

Figure 17 shows that all of these mAbdAbs bound IL-4. Purified anti-human IL4 mAb alone (Pascolizumab) was included in this assay but did not generate a binding curve as an error was made when diluting this mAb for use in the assay (Pascolizumab has
been used successfully in all other subsequent IL-4 binding ELISAs). Purified anti-human IL13 mAb was included as a negative control for IL-4 binding.

The same mAbdAbs supernatants were also tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 18 (some samples were prepared and tested in duplicate and this has been annotated as sample 1 and sample 2).

Figure 18 shows that all of these anti-IL4mAb-anti-IL13dAbs bound IL-13. Purified anti-human IL13 mAb alone was included in this assay but did not generate a binding curve as an error was made when diluting this mAb for use in the assay (purified anti-human IL13 mAb has been used successfully in all other subsequent IL-13 binding ELISAs). Purified anti-IL4 mAb (Pascolizumab) was included as a negative control for binding to IL-13. Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as this dAb is not detected by the secondary detection antibody.

The purified anti-IL4mAb-anti-IL13dAbs, 'PascoH-G4S-474', 'PascoL-G4S-474' and 'PascoHL-G4S-474', were also tested for binding to human IL-4 in a direct binding ELISA (as described in method 2). These data are shown in Figure 19.

These purified anti-IL4mAb-anti-IL13dAbs bound IL-4. The binding activity of these mAbdAbs was approximately equivalent (within 2-fold) to purified anti-IL4 mAb alone (Pascolizumab). An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-4 in this assay.

These same purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, were also tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 20A.

These purified anti-IL4mAb-anti-IL13dAbs bound IL-13. An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-13 in this assay. Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as the dAb is not detected by the secondary detection antibody; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

Purified PascoH-474, PascoH-TVAAPS-474, PascoH-ASTKG-474 and PascoH-ELQLE-474 were also tested for binding to cynomolgus IL-13 in a direct binding ELISA, as described in method 17 (PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed were also included in this assay, the construction of these molecules is described in Example 18). A graph showing representative data is shown in Figure 20B.
Purified PascoH-474, PascoH-TVAAPS-474, PascoH-ASTKG-474 and PascoH-ELQLE-474 all bound cynomolgus IL-13. Purified anti-human IL4 mAb alone (Pascolizumab) was included in this assay as a negative control for binding to IL-13. Purified anti-human IL13 mAb was included as a positive control for cynomolgus IL-13 binding. Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as the dAb is not detected by the secondary detection antibody; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

Example 3
Binding of mAbdAbs to human IL-13 and human IL-4 by surface plasmon resonance (BIACore™)

3.1 Binding of anti-IL13mAb-anti-IL4dAbs to IL-13 and IL-4 by BIACore™

mAbdAbs (in CHO cell supernatants, prepared as described in section 1.5) were tested for binding to human IL-13 using BIACore™ at 25°C (as described in method 4). For this data set, two IL-13 concentration curves (10OnM and 1nM) were assessed and relative response capture levels of between 1000 and 1300 (approximately) were achieved for each mAbdAb construct. Due to the limited number of concentrations of IL-13 used, the data generated are more suitable for ranking of constructs rather than exact kinetic measurements. These data are shown in Table 6.

</tbody>
</table>
All of these anti-IL13mAb-anti-IL4dAbs bound IL-13 with similar binding affinities which were approximately equivalent to the binding affinity of purified anti-human IL13 mAb alone. These data suggested that the addition of linkers and/or anti-IL4 dAbs to the heavy chain of the anti-IL13 mAb, did not affect the IL-13 binding affinity of the mAb component within these mAbdAb constructs.

These mAbdAbs were also tested for binding to human IL-4 using BIAcore™ at 25°C (as described in method 5). These data are shown in Table 7. For this data set, four IL-4 concentration curves (512, 128, 32 and 8nM) were assessed and approximate relative response capture levels for each mAbdAb tested are indicated in the table. Note that the anti-IL-4 dAbs alone were not tested in this assay as the dAbs cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay.

</table>
Caveats were observed for some of the above data sets. Poor curve fits were observed for some data sets (*), the actual binding affinity values that have been determined for these data should therefore be treated with caution. Positive dissociation was seen for some curves (**), the actual binding affinity values that have been determined for these data should therefore be treated with caution. In addition, BIAcore™ was unable (ie. not sensitive enough) to determine on and off rates for all mAbdAb constructs containing the DOM9-1 12-210 dAb, due to the exceptionally tight binding of these mAbdAbs to IL-4. Determination of binding kinetics for these mAbdAbs for IL-4 was further hampered by observed positive dissociation effects. These data are shown in Figure 21.

Similar data was obtained in an additional experiment. These data are shown in Figure 22.

These 2 independent data sets indicated that all of the anti-IL13mAb-anti-IL4dAbs bound IL-4, but the binding affinities varied depending on the linker used to join the anti-IL4 dAb to the anti-IL13 mAb heavy chain. In this experiment, the presence of a linker was found to enhance the binding affinity for IL-4 of the anti-IL4 dAb component (when placed on the heavy chain) in the mAbdAb format. For example

the molecules having TVAAPS or ELQLEESCAEAQDGELDG linkers appear to be more potent binders. No binding to IL-4 was observed when no anti-IL4 dAb was present in the mAbdAb construct. It was not possible to measure the binding affinity of the 586-linker-210 mAbdAbs for IL-4, due to the fact that the DOM9-1 12-210 component of these mAbdAbs binds very tightly and hence the off-rate is too small to determine using BIAcore™.

Purified anti-IL13mAb-anti-IL4dAbs were also tested for binding to human IL-13 and human IL-4 using BIAcore™ at 25°C (as described in methods 4 and 5). These data are shown in Table 8.

586H-TVAAPS-25, 586H-TVAAPS-154 and 586H-TVAAPS-210 all bound IL-13 with similar binding affinities and this was approximately equivalent to the binding affinity of purified anti-human IL13 mAb alone. 586H-TVAAPS-25, 586H-TVAAPS-154 and 586H-TVAAPS-210 all bound IL-4. It was not possible to measure the binding affinity of 586-TVAAPS-210 for IL-4, due to the fact that the DOM9-1 12-210 component of this mAbdAb bound very tightly and hence the off-rate was too small to determine using BIAcore™. Note that the anti-IL-4 dAbs alone (DOM9-1 55-25, DOM9-1 155-154 and DOM9-1 12-210) were not tested in this assay format as the dAbs cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay.

3.2 Binding of anti-IL4mAb-anti-IL13dAbs to IL-4 and IL-13 by BIAcore™
mAbdAbs (in CHO cell supernatants prepared as described in section 1.5) were tested for binding to human IL-4 using BIAcore™ at 25°C (as described in method 5). These data are shown in Table 9 (some samples were prepared and tested in duplicate - this has been annotated as sample 1 and sample 2). For this data set, four IL-4 concentrations curves (100nM, 10nM, 1nM and 0.1nM) were assessed and approximate relative response capture levels for each mAbdAb tested are indicated.
in the table. An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-4 in this assay.

</table>

All of the anti-IL4mAb-anti-IL13dAbs tested bound IL-4 with similar binding affinities and this was approximately equivalent to the binding affinity of the anti-human IL4 mAb alone (Pascolizumab). PascoL-EPKSC-474 bound IL-4 approximately 2-fold less potently than Pascolizumab. These data suggested that the addition of linkers and the anti-IL13 dAb to either the heavy chain or the light chain of Pascolizumab, did not overtly affect the IL-4 binding affinity of the mAb component within the mAbdAb construct.

These mAbdAbs were also tested for binding to human IL-13 using BIAcore™ at 25°C (as described in method 4). These data are shown in Table 10 (some samples were prepared and tested in duplicate - this has been annotated as sample 1 and sample 2). For this data set, four IL-13 concentrations curves (128nM, 32nM, 8nM and 2nM) were assessed and approximate relative response capture levels for each mAbdAb tested are indicated in the table.

</table>

Binding affinity data for constructs tested in experiment 2 are also shown in figure 23.

All of the anti-IL4mAb-anti-IL13dAbs bound IL-13. In most cases the presence of a linker did not appear to enhance the binding affinity for IL-13 of the anti-IL13 dAb component when placed on the heavy chain of the anti-IL4 mAb. However, the presence of a linker did appear to enhance the binding affinity for IL-13 of the anti-IL13 dAb component when placed on the light chain of the anti-IL4 mAb. PascoL-TVAAPS-474 appeared to have the most potent IL-13 binding affinity in this experiment.
Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, purified anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay. An isotype-matched mAb (with specificity for an irrelevant antigen) was also included as a negative control for binding to IL-13 in this assay.

Purified anti-IL4mAb-anti-IL13dAbs were also tested for binding to human IL-4 and human IL-13 using BIACore™ at 25°C (as described in methods 4 and 5). These data are shown in Table 11.

</table>

In this experiment PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474 all bound IL-4 with similar binding affinities and this was approximately equivalent to the binding affinity of the anti-human IL4 mAb alone (Pascolizumab). They also all bound IL-13. Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

### 3.3 Stoichiometry of binding of IL-13 and IL-4 to the anti-IL4mAb-anti-IL13dAbs using BIACore™

Purified anti-IL4mAb-anti-IL13dAbs were evaluated for stoichiometry of binding for IL-13 and IL-4 using BIACore™ (as described in method 7). These data are shown in Table 12.

### Table 12

PascoH-G4S-474, PascoH-474 and PascoL-G4S-474 were able to bind to nearly two molecules of IL-13 and two molecules of IL-4. PascoHL-G4S-474 was able to bind nearly two molecules of IL-4 and nearly four molecules of IL-13. These data indicated that the constructs tested could be fully occupied by the expected number of IL-13 or IL-4 molecules.

**Example 4**
**Neutralisation potency of mAbdAbs in IL-13 and IL-4 bioassays**

4.1 Anti-IL13mAb-anti-IL4dAbs

Purified anti-IL13mAb-anti-IL4dAbs were tested for neutralisation of human IL-13 in a TF-1 cell bioassay (as described in method 8). These data are shown in Figure 24.

Purified anti-IL13mAb-anti-IL4dAbs, 586H-TVAAPS-25, 586H-TVAAPS-154 and 586H-TVAAPS-210, fully neutralised the bioactivity of IL-13 in a TF-1 cell bioassay. The neutralisation potencies of these mAbdAbs were within 2-fold of purified anti-human IL-13 mAb alone. The purified anti-human IL-4 mAb (Pascolizumab) and purified anti-IL4 dAbs (DOM9-155-25, DOM9-155-154 or DOM9-112-210) were included as negative controls for neutralisation of IL-13 in this assay.

The purified anti-IL13mAb-anti-IL4dAbs, 586H-TVAAPS-25, 586H-TVAAPS-154 and 586H-TVAAPS-210, were also tested for neutralisation of human IL-4 in a TF-1 cell bioassay (as described in method 9). These data are shown in Figure 25.

586H-TVAAPS-210 fully neutralised the bioactivity of IL-4 in this TF-1 cell bioassay. The neutralisation potency of this mAbdAb was within 2-fold of purified anti-human IL-4 dAb alone (DOM9-112-210). 586H-TVAAP S-25 and 586H-TVAAPS-154 did not neutralise the bioactivity of IL-4 and this was in contrast to the purified anti-human IL-4 dAbs alone (DOM9-155-25 and DOM9-155-154). As demonstrated by BIAcore™, purified 586H-TVAAPS-25 and 586H-TVAAP S-154 had 1.1 nM and 0.49 nM binding affinities (respectively) for IL-4. IL-4 binds the IL-4 receptor very tightly (binding affinities of approximately 50 pM have been reported in literature publications) and thus the observation that both 586H-TVAAPS-25 or 586H-TVAAP S-154 were unable to effectively neutralise the bioactivity of IL-4 in the TF-1 cell bioassay maybe a result of the relative lower affinity of these mAbdAbs for IL-4 compared to the potency of IL-4 for the IL-4 receptor.

Purified anti-human IL-4 mAb (Pascolizumab) was included as a positive control for neutralisation of IL-4 in this bioassay. Purified anti-human IL-13 mAb was included as a negative control for neutralisation of IL-4 in this bioassay.
4.2 Anti-IL4mAb-anti-IL13dAbs
The purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, were tested for neutralisation of human IL-4 in a TF-1 cell bioassay (as described in method 9). These data are shown in Figure 26.

Purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, fully neutralised the bioactivity of IL-4 in a TF-1 cell bioassay. The neutralisation potencies of these mAbdAbs were approximately equivalent to that of purified anti-human IL4 mAb alone (Pascolizumab). Purified anti-human IL-13 mAb, purified DOM10-53-474 dAb and a dAb with specificity for an irrelevant antigen (negative control dAb) were also included as negative controls for neutralisation of IL-4 in this bioassay.

The purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, were tested for neutralisation of human IL-13 in a TF-1 cell bioassay (as described in method 8). These data are shown in Figure 27.

Purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, fully neutralised the bioactivity of IL-13 in a TF-1 cell bioassay. The neutralisation potencies of these mAbdAbs were within 3-fold of purified anti-IL13 dAb alone (DOM1 0-53-474). Purified anti-human IL-13 mAb was also included as a positive control for IL-13 neutralisation in this bioassay. A dAb with specificity for an irrelevant antigen (negative control dAb) and purified anti-human IL4 mAb alone (Pascolizumab) were also included as negative controls for neutralisation of IL-4 in this bioassay.

The purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, were also tested for simultaneous neutralisation of human IL-4 and human IL-13 in a dual neutralisation TF-1 cell bioassay (as described in method 10). These data are shown in Figure 28.

Purified anti-IL4mAb-anti-IL13dAbs, PascoH-G4S-474, PascoH-474, PascoL-G4S-474 and PascoHL-G4S-474, fully neutralised the bioactivity of both IL-4 and IL-13 in a dual neutralisation TF-1 cell bioassay. The neutralisation potencies of these mAbdAbs were approximately equivalent to that of a combination of purified anti-human IL4 mAb (Pascolizumab) and purified anti-IL13 dAb (DOM1 0-53-474). Purified anti-human IL-13 mAb alone, purified anti-human IL-4 mAb alone (Pascolizumab) and the anti-human IL-13 dAb (DOM1 0-53-474) alone (which were included as negative controls) did not fully neutralise the bioactivity of both IL-4 and IL-13 in this dual IL-4 and IL-13 neutralisation bioassay.
Example 5

SEC-MALLS analysis of dAbs

Antigen-specific dAbs were characterized for their solution state by SEC-MALLS (size-exclusion chromatography - multi-angle laser light scattering) and the results are shown in Table 13: the DOM10-53-474, dAb exists as a monomer in solution whilst all DOM9 dAbs (DOM9-1 12-210, DOM9-1 55-25, DOM9-155-147 and DOM9-155-154) can form stable dimers (and in some instances tetramers).

5.1. Preparation of the proteins
Samples were purified and dialysed into appropriate buffer e.g. PBS. Samples were filtered after dialysis and the concentration determined (0.43mg/ml DOM-155-25), (1.35mg/ml DOM9-155-147) and 1.4mg/ml DOM9-155-159). DOM10-53-474 and DOM9-1 12-210 were adjusted to 1mg/ml.
BSA was purchased from Sigma and used without further purification.

5.2. Size-Exclusion chromatography and Detector Set-up
Shimadzu LC-20AD Prominence HPLC system with an autosampler (SIL-20A) and SPD-20A Prominence UV/Vis detector was connected to Wyatt Mini Dawn Treos (MALLS, multi-angle laser light scattering detector) and Wyatt Optilab rEX DRI (differential refractive index) detector. The detectors were connected in the following order - LS-UV-RI. Both RI and LS instruments operated at a wavelength of 488nm. TSK2000 (Tosoh corporation)) column were used (silica-based HPLC column) with mobile phase of 50mM phosphate buffer (without salt), or 1xPBS, both at pH7.4. The flow rate used is 0.5 or 1ml/min, the time of the run was adjusted to reflect different flow rates (45 or 23 min) and was not expected to have significant impact onto separation of the molecules. Proteins were prepared in buffer to a concentration of 1mg/ml and injection volume was 100ul.

5.3. Detector Calibration
The light-scattering detector was calibrated with toluene according to manufacturer's instructions.

5.4. Detector Calibration with BSA
The UV detector output and RI detector output were connected to the light scattering instrument so that the signals from all three detectors could be simultaneously collected with the Wyatt ASTRA software. Several injections of BSA in a mobile phase of PBS (1ml/min) are run over a Tosoh TSK2000 column with UV, LS and RI signals collected by the Wyatt software. The traces are then analysed using ASTRA software, and the signals are normalised aligned and corrected for band broadening following manufacturer's instructions. Calibration constants are then averaged and input into the template which is used for future sample runs.
5.5. Absolute molar mass calculations

100μl of each sample were injected onto appropriate pre-equilibrated column. After SEC column the sample passes through 3 on-line detectors - UV, MALLS (multi-angle laser light scattering) and DRI (differential refractive index) allowing absolute molar mass determination. The dilution that takes place on the column is about 10 fold, and the concentration at which in-solution state was determined as appropriate.

The basis of the calculations in ASTRA as well as of the Zimm plot technique, which is often implemented in a batch sample mode is the equation from Zimm [J. Chem. Phys. 16, 1093-1099 (1948)]:

\[
\frac{R_g}{K^*c} = \frac{MP}{\lambda} - 2\Lambda c M^3 P \beta \\
\text{(Eq. 1)}
\]

where

- \(c\) is the mass concentration of the solute molecules in the solvent (g/mL)
- \(M\) is the weight average molar mass (g/mol)
- \(A_2\) is the second virial coefficient (mol mL / g²)
- \(K^* = 4p^2 n_0^2 (dn/dc)^2 10^4 / n_A^{-1}\) is an optical constant where \(n_0\) is the refractive index of the solvent at the incident radiation (vacuum) wavelength, \(n_0\) is the incident radiation (vacuum) wavelength, expressed in nanometers, \(N_A\) is Avogadro’s number, equal to 6.022 x 10²³ mol⁻¹, and \(dn/dc\) is the differential refractive index increment of the solvent-solute solution with respect to a change in solute concentration, expressed in mL/g (this factor must be measured independently using a dRI detector).
- \(P(q)\) is the theoretically-derived form factor, approximately equal to \(1 - 2N^2 \langle r^2 \rangle / 3J_4\). \(\mu = (4\pi / \lambda)\langle \sin \theta / \sin 2\theta \rangle\), and \(\langle r^2 \rangle\) is the mean square radius. \(P(q)\) is a function of the molecules’ z-average size, shape, and structure.
- \(R_g\) is the excess Rayleigh ratio (cm⁻¹)

This equation assumes vertically polarized incident light and is valid to order \(c^2\).

To perform calculations with the Zimm fit method, which is a fit to \(R_g/K^*c\) vs. \(\sin^2(q/2)\), we need to expand the reciprocal of Eq. 1 first order in \(c\):

To perform calculations with the Zimm fit method, which is a fit to

\[
\frac{K^*c}{R_g} = \frac{1}{MP(\theta)} + 2A_2c \\\n\text{Eq. 2}
\]
The appropriate results in this case are

\[ M = \left( \frac{K^* c}{R_0} - 2 A_c c \right)^{-1} \quad \text{Eq. 3} \]

and

\[ \langle r^2 \rangle = \frac{3m_b A^2 M}{8h^2} \quad \text{Eq. 4} \]

where

\[ m_b \equiv \frac{d}{d} \left[ \frac{K^* c}{R_0} \right] / \left[ \sin^2 (\theta / 2) \right] \quad \text{Eq. 5} \]

The calculations are performed automatically by ASTRA software, resulting in a plot with molar mass determined for each of the slices [Astra manual]. Molar mass obtained from the plot for each of the peaks observed on chromatogram was compared with expected molecular mass of a single unit of the protein. This provides a basis to form conclusions about in-solution state of the protein. Representative data is shown in Table 13.

**DOM10-53-474**

Single peak with the average molar mass defined as \(~14\text{kDa}\) indicating a monomeric state in solution, shown in Figure 29.

**DOM9-1 12-210**

Single peak with the molar mass defined as 30 kDa indicating a dimeric state in solution, shown in Figure 30.

**DOM9-1 55-25**

Nice symmetrical peak but running at the buffer front. The mid part of the peak has been used for molar mass determination (see figure below with all three signals overlaid). Molar mass is 28 kDa which represents a dimeric dAb, shown in Figure 31. Overlay of all three signals (Figure 32).
DOM9-155-147

The main peak is assigned with molar mass of 26kDa over the right part of the peak and increasing steeply over the left part of the peak up to 53kDa. The peak most likely represents a dimer and a smaller fraction of tetramer in a rapid equilibrium. A much smaller peak eluting at 7.6 min, represents tetrameric protein with molar mass of 51kDa (Figure 33).

DOM9-155-159

The protein runs as a single symmetric peak, with average molar mass assigned at ~28kDa indicating a dimeric state in solution (Figure 34)

Control for MW assignment by SEC-MALLS: BSA

Each BSA run for each of the experiments set out above resulted in the expected MW, e.g. 2 peaks with molar mass of 67 and 145kDa (monomer and dimer) (Figure 35).

Example 6

Generation of trispecific mAbdAbs

Trispecific mAb-dAbs were constructed either by generating VH and VL sequences by assembly PCR which were then cloned into existing mAbdAb expression vectors or by sub-cloning existing VH and VL regions from mAb expression vectors into existing mAbdAb expression vectors, such that when expressed, the trispecific mAbdAb has dAbs attached to both the C-terminus of the heavy and light chains.

A linker sequence was used to join the domain antibody to heavy chain CH3 or light chain CK. A schematic diagram of a trispecific mAbdAb molecule is shown in Figure 36 (the mAb heavy chain is drawn in grey; the mAb light chain is drawn in white; the dAbs are drawn in black).

A schematic diagram illustrating the construction of a trispecific mAbdAb heavy chain (top illustration) and a trispecific mAbdAb light chain (bottom illustration) is shown below.

HindIII Spel BamHI EcoRI

V\textsubscript{H} CH1 CH2 CH3 dAb

linker

HindIII BsiWI BamHI EcoRI

V\textsubscript{L} CK dAb

linker
For the heavy chain the term $V_H$ is the monoclonal antibody variable heavy chain sequence; 'CH1', 'CH2' and 'CH3' are human IgGl heavy chain constant region sequences; 'linker' is the sequence of the specific linker region used; 'dAb' is the domain antibody sequence. For the light chain: $V_L$ is the monoclonal antibody variable light chain sequence; 'CK' is the human light chain constant region sequence; 'linker' is the sequence of the specific linker region used; 'dAb' is the domain antibody sequence.

A mammalian amino acid signal sequence (as shown in SEQ ID NO: 64) was used in the generation of these constructs.

### 6.1 Trispecific anti-IL18mAb-anti-IL4dAb-anti-IL13dAb

A trispecific anti-IL18mAb-anti-IL4dAb-anti-IL13dAb (also known as IL18mAb-210-474) was constructed by grafting a sequence encoding an anti-human IL-4 domain antibody (DOM9-1 12-210) onto a sequence encoding the heavy chain and a sequence encoding an anti-IL13 domain antibody (DOM10-53-474) onto a sequence encoding the light chain of an anti-human IL-18 humanised monoclonal antibody. A G4S linker was used to join the anti-IL4 domain antibody onto the heavy chain of the monoclonal antibody. A G4S linker was also used to join the anti-IL13 domain antibody onto the light chain of the monoclonal antibody.

IL18mAb-2 10-474 was expressed transiently in CHOK1 cell supernatants, and following quantification of IL18mAb-210-474 in the cell supernatant, analysed in a number of IL-18, IL-4 and IL-13 binding assays.

### 6.2 Trispecific anti-IL5mAb-anti-IL4dAb-anti-IL13dAb

A trispecific anti-IL5mAb-anti-IL4dAb-anti-IL13dAb (also known as Mepo-2 10-474) was constructed by grafting a sequence encoding an anti-human IL-4 domain antibody DOM9-1 12-210 (SEQ ID NO: 4) onto a sequence encoding the heavy chain of an anti-human IL-5 humanised monoclonal antibody (SEQ ID NO: 65), and grafting a sequence encoding an anti-IL13 domain antibody DOM10-53-474 (SEQ ID NO: 5) onto a sequence encoding the light chain of an anti-human IL-5 humanised monoclonal antibody (SEQ ID NO: 66). A G4S linker was used to join the anti-IL4 domain antibody onto the heavy chain of the monoclonal antibody. A G4S linker was also used to join the anti-IL13 domain antibody onto the light chain of the monoclonal antibody.
This mAbdAb was expressed transiently in CHOK1 and HEK293-6E cell supernatants, and following quantification in the cell supernatant, analysed in a number of IL-4, IL-5 and IL-13 binding assays.

Mature human IL-4 amino acid sequence (without signal sequence) is given in SEQ ID NO: 62.
Mature human IL-13 amino acid sequence (without signal sequence) is given in SEQ ID NO: 63.

**6.4 Expression and purification of trispecific mAbdAbs**

DNA sequences encoding trispecific mAbdAb molecules were cloned into mammalian expression vectors (RIn, RId or pTT) using standard molecular biology techniques. The trispecific mAbdAb expression constructs were transiently transfected into one or both of CHOK1 or HEK293-6E cells, expressed at small scale (3mls to 150mls). The expression procedures used to generate the trispecific mAbdAbs were the same as those routinely used to express and monoclonal antibodies.
Some of the constructs were purified using immobilised Protein A columns and quantified by reading absorbance at 280nm.

**Example 7**

**Binding of trispecific mAbdAbs to human IL-4, human IL-13 and human IL-18 by ELISA**

7.1 Binding of IL-18mAb-210-474 to IL-4, IL-13 and IL-18 by ELISA

Trispecific mAbdAb IL18mAb-2 10-474 (supernatants) prepared as described in Example 6 (SEQ ID NO: 69 and 70), was tested for binding to human IL-18, human IL-13 and human IL-4 in direct binding ELISAs (as described in methods 1, 2 and 3) and these data are shown in Figures 37, 38 and 39 respectively (IL18mAb-210-474 was prepared and tested a number of times and this has been annotated in the figures as sample 1, sample 2, sample 3, etc).

These figures show that IL18mAb-21 0-474 bound IL-4, IL-13 and IL-18 by ELISA. Purified anti-human IL18 mAb was included in the IL-18 binding ELISA as a positive control for IL-18 binding. The anti-IL-4 dAb (DOM9-1 12-210) was not tested in the IL-4 binding ELISA as this dAb is not detected by the secondary detection antibody; instead, purified anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this ELISA. The anti-IL-13 dAb (DOM1 0-53-474) was not tested in the IL-13 binding ELISA as this dAb is not detected by the secondary detection antibody; instead, purified anti-human IL-13 mAb was included as a positive control to demonstrate IL-13 binding in this ELISA. As shown in the figures, negative control mAbs to an irrelevant antigen were included in each binding ELISA.

In each ELISA the binding curve for IL18mAb-2 10-474 sample 5 sits apart from the binding curves for the other IL18mAb-210-474 samples. The reason for this is unknown however, it maybe due to a quantification issue in the human IgG quantification ELISA for this particular IL18mAb-210-474 sample 5.

7.2 Binding of Mepo-21 0-474 to IL-4 and IL-13 by ELISA

Trispecific mAbdAbs Mepo-21 0-474 (supernatant) prepared as described in section 1 (sequence ID numbers 71 and 72), were tested for binding to human IL-13 and human IL-4 in direct binding ELISAs (as described in methods 1 and 2 respectively) and these data are shown in Figures 40 and 41 respectively (Mepo-210-474 was prepared and tested in quadruplicate and this has been annotated as sample 1, sample 2, sample 3 and sample 4).

These figures illustrate that Mepo-210-474 bound IL-4 and IL-13 by ELISA. The anti-IL-4 dAb (DOM9-1 12-210) was not tested in the IL-4 binding ELISA as this dAb is not detected by the secondary detection antibody; instead, purified anti-human IL4 mAb
(Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this ELISA. The anti-IL-13 dAb (D0M1 0-53-474) was not tested in the IL-13 binding ELISA as this dAb is not detected by the secondary detection antibody; instead, purified anti-human IL-13 mAb was included as a positive control to demonstrate IL-13 binding in this ELISA. As shown in Figures 40 and 41, negative control mAbs to an irrelevant antigen were included in each binding ELISA.

Mepo-210-474 sample 1 and sample 2 were prepared in one transient transfection experiment and Mepo-210-474 sample 3 and sample 4 were prepared in another separate transient transfection experiment. All four samples bound IL-13 and IL-4 in IL-13 and IL-4 binding ELISAs. However, the reason for the different binding profiles of samples 1 and 2 versus samples 3 and 4 is unknown, but may reflect a difference in the quality of the mAbdAb (in the supernatant) generated in each transfection experiment.

**Example 8**

*Binding of trispecific mAbdAbs to human IL-4, human IL-5, human IL-13 and human IL-18 by surface plasmon resonance (BIAcore™)*

8.1 Binding of IL-18mAb-210-474 to IL-4, IL-13 and IL-18 by BIAcore™

Trispecific mAbdAb IL18mAb-210-474 (supernatants) prepared as described in Example 6.1 (SEQ ID NO: 69 and 70), was tested for binding to human IL-4, human IL-13 and human IL-18 using BIAcore™ at 25°C (as described in methods 4, 5 and 6 respectively). Capture levels were within the range of approximately 400 to 850 Response Units. Three concentrations of each analyte were tested (256, 32 and 4nM). The resulting data are shown in Table 15 (samples were prepared and tested in triplicate, this has been annotated as sample 1, sample 2 and sample 3).

The trispecific mAbdAb bound IL-4, IL-13 and IL-18 using BIAcore™. The binding affinity of the mAbdAb for IL-18 was approximately equivalent to that of purified anti-human IL18 mAb alone, which was included in this assay as a positive control for IL-18 binding and in order to directly compare to the binding affinity of the mAbdAb. It was not possible to determine the absolute binding affinity of the mAbdAb for IL-4, due to the fact that the D0M9-1 12-210 component of this trispecific mAbdAb bound very tightly to IL-4 and hence the off-rate was too small to determine using BIAcore™. The anti-IL-4 dAb alone (D0M9-1 12-210) was not tested in this assay as this dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was included as a positive control to demonstrate IL-4 binding in this assay. The anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as this dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was included as a positive control to demonstrate IL-13 binding in this assay.

8.2 Binding of Mepo-210-474 to IL-4, IL-5 and IL-13 by BIAcore™

Trispecific mAbdAb Mepo-210-474 (supernatants) prepared as described in Example 6.2 (SEQ ID NO: 71 and 72), was tested for binding to human IL-4, human IL-5 and human IL-13 using BIAcore™ at 25°C (as described in methods 5, 11 and 4 respectively). Capture levels were within the range of approximately 550 to 900 Response Units. For IL-4 and IL-13 binding five concentrations of each analyte were tested (256, 64, 16, 4 and 1nM). For IL-5 binding four concentrations of each analyte were tested (64, 16, 4 and 1nM). The resulting data are shown in Table 16.

*unable to determine KD due to positive dissociation effects and sensitivity level of BIAcore™ technique*
Mepo-210-474 bound IL-4, IL-5 and IL-13 using BIAcore™. The binding affinity of Mepo-210-474 for IL-5 was approximately equivalent to that of purified anti-human IL5 mAb (Mepolizumab) alone, which was included in this assay as a positive control for IL-5 binding and in order to directly compare to the binding affinity of Mepo-210-474. It was not possible to determine the absolute binding affinity of Mepo-210-474 for IL-4, due to the fact that the DOM9-1 12-210 component of this trispecific mAbdAb bound very tightly to IL-4 and hence the off-rate was too small to determine using BIAcore™. The anti-IL-4 dAb alone (DOM9-1 12-210) was not tested in this assay as this dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was included as a positive control to demonstrate IL-4 binding in this assay. The anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as this dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was included as a positive control to demonstrate IL-13 binding in this assay.

### Example 9

#### Stoichiometry

9.1 Stoichiometry of binding of IL-4, IL-13 and IL-18 to IL-18mAb-21 0-474 using BIAcore™

IL18mAb-21 10-474 (in CHO cell supernatants prepared as described in section 1) (SEQ ID NO: 69 and 70), were evaluated for stoichiometry of binding for IL-4, IL-13 and IL-18 using BIAcore™ (as described in method 7). These data are shown in Table 17 (R-max is the saturated binding response and this is required to calculate the stoichiometry, as per the given formulae in method 7). The concentration of each of the cytokines was 500nM. The injection position refers to the order in which each of the cytokines was added.

</tbody>
</table>
The stoichiometry data indicated that IL18mAb-210-474 bound approximately two molecules of IL-18, two molecules of IL-13 and only one molecule of IL-4. The anti-IL4 dAb alone (DOM9-1 12-210) is known to be a dimer in solution state and is only able to bind one molecule of IL-4. It is therefore not unexpected that IL18mAb-210-474 would bind only one molecule of IL-4. These data indicated that the molecules tested could be fully occupied by the expected number of IL-18, IL-13 and IL-4 molecules. The stoichiometry data also indicated that the order of capture of the cytokines appears to be independent of the order of addition of the cytokines.

**Example 10**

**10.1 Generation of a Dual Targeting anti-TNF/anti-EGFR mAbdAb**

This dual targeting mAbdAb was constructed by fusion of a dAb to the C-terminus of the mAb heavy chain. The anti-TNF mAb heavy and light chain expression cassettes had been previously constructed. The restriction sites which were used for cloning are shown below (Figure 42).

To introduce restriction sites for dAb insertion in the heavy chain, site directed mutagenesis was used to create Sail and HindIII cloning sites using the mAb heavy chain expression vector as a template. DNA coding an anti-EGFR dAb (DOM16-39-542) was then amplified by PCR (using primers coding Sail and HindIII ends) and inserted into the modified 3’ coding region, resulting in a linker of ‘STG’ (serine, threonine, glycine) between the mAb and the dAb.

Sequence verified clones (SEQ ID NO: 170 and 169) for light and heavy chains respectively) were selected and large scale were made using Qiagen Mega Prep Kit following the manufacturer’s protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 73 and 74)

**10.2 Purification and SEC analysis of the Dual Targeting anti-TNF/anti-EGFR mAbdAb**

The anti-TNF/anti-EGFR mAbdAb was purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis (Figure 43) of the purified sample shows non-reduced sample running at -170kDa whilst reduced sample shows two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-TNF/anti-EGFR mAbdAb was applied onto a Superdex-200 10/30 HR column (attached to an Akta Express
FPLC system) pre-equilibrated and running in PBS at 0.5ml/min. The SEC profile shows a single species running as a symmetrical peak (figure 44).

**10.3 Binding Affinities of the Dual Targeting anti-TNF/anti-EGFR mAbdAb**

Binding affinities to EGFR and TNF were determined as described in methods 13 and 14 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 45) of this mAbdAb was calculated to be 39.1 nM whilst the control, an anti-EGFR mAb gave an EC50 value of 3.4nM. In the anti-TNF bioassay (Figure 46) the potency was of the mAbdAb was 3pM (0.0028nM) whilst an anti-TNF control mAb produced an EC50 of 104pM. In conclusion, assay data shows that the construct of example 10, a dual targeting anti-TNF/anti-EGFR mAbdAb is potent against both antigens.

**10.4 Rat PK of the Dual Targeting anti-TNF/anti-EGFR mAbdAb**

This molecule was tested for its in vivo pharmacokinetic properties in the rat. The anti-TNF/anti-EGFR mAbdAb was administered i.v. to three rats, and serum samples collected over a period of 7 days (168 hours). The concentration of drug remaining at various time points post-dose was assessed by ELISA against both TNF & EGFR. Results are shown in Figure 125.

The PK parameters confirmed that this molecule had a long half life, in the same region as that previously observed for unmodified adalimumab (125 hours). Further details are shown in Table 17.1

**Example 11**

**11.1 Generation of a Dual Targeting anti-TNF/anti-VEGF mAbdAb**

An anti-TNF/anti-VEGF mAbdAb was produced employing a similar strategy described for example 10. For construction of the heavy chain expression cassette, vector DNA encoding the heavy chain of example 10 was taken as a starting point. The anti-EGFR dAb was excised using the restriction enzymes Sail and HindIII. DOM1 5-26-593, an anti-VEGF dAb was amplified by PCR (using primers coding Sail
and Hind III ends) and ligated into the vector backbone which previously had the anti-EGFR dAb excised using the same restriction sites, resulting in a linker of 'STG' (serine, threonine, glycine) between the mAb and the dAb.

Sequence verified clones (SEQ ID NO: 169 and 168 for light and heavy chains respectively) were selected and large scale DNA preparations were made and the anti-TNF/anti-VEGF mAb-dAb was expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 73 and 75).

**11.2 Purification and SEC analysis of the Dual Targeting anti-TNF/anti-VEGF mAb-dAb**

The anti-TNF/anti-VEGF mAb-dAb (designated DMS4000) was purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis (figure 47) of the purified sample shows non-reduced sample running at -170kDa whilst reduced sample shows two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-TNF/anti-VEGF mAb-dAb was applied onto a Superdex-200 10/30 HR column (attached to an Akta Express FPLC system) pre-equilibrated and running in PBS at 0.5ml/min. The SEC profile shows a single species running as a symmetrical peak (figure 48).

**11.3 Binding Affinities of the Dual Targeting anti-TNF/anti-VEGF mAb-dAb**

Binding affinities to VEGF and TNF were determined as described in methods 12 and 14 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-VEGF potency (Figure 49) of this mAb-dAb was calculated to be 57pM whilst the control, an anti-VEGF mAb gave an EC50 value of 366pM. In the anti-TNF bioassay (Figure 50) the potency was 10pM whilst an anti-TNF control mAb produced an EC50 of 22pM. In conclusion, assay data shows that the molecule of Example 11, a dual targeting anti-TNF/anti-VEGF mAb-dAb is potent against both antigens.

**11.4 Rat PK of the Dual Targeting anti-TNF/anti-VEGF mAb-dAb**

This molecule was tested for its in vivo pharmacokinetic properties in the rat. The anti-TNF/anti-VEGF mAb-dAb was administered i.v. to three rats, and serum samples collected over a period of 10 days (240 hours). The concentration of drug remaining...
at various time points post-dose was assessed by ELISA against both TNF & VEGF. The results are shown in Figure 126.

The PK parameters confirmed that this molecule had in vivo pharmacokinetic properties that compared with those of unmodified adalimumab. The shorter observed $t_{1/2}\beta$ for the VEGF component is not considered to be significant and may be an assay artefact. Further details are shown in Table 17.2.

11.5 Generation of an alternative anti-TNF/anti-VEGF mAbdAb

An alternative anti-TNF/anti-VEGF mAbdAb was constructed in a similar way to that described above in Example 11.1, using the same anti-TNF mAb linked to a VEGF dAb on the C-terminus of the heavy chain using an STG linker. The anti-VEGF dAb used in this case was DOM1 5-1 0-1 1. This molecule was expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 73 and 185). This molecule expressed to give a mAbdAb of similar expression levels to that described in Example 11.2, however when tested for potency in the same VEGF assay as described in Example 11.3 it was found to have undetectable levels of inhibition of VEGF binding to VEGF receptor in this assay.

Example 12

12.1 Generation of a Dual Targeting anti-VEGF/anti-IL1R1 dAb-extended IgG

Two dual targeting dAb-extended IgG molecules were constructed using standard molecular biology techniques following a strategy of insertion of Dummy V domain coding regions in between dAb and constant regions of both chains.

For the light chain, the anti-IL1R1 dAb DOM4-1 30-54 was previously cloned into an expression cassette with Sail and BsiWI sites (Figure 51) to produce a dAb-Ck chain. To produce the dAb-extended IgG light chain, Dummy Vk region was amplified by PCR with primers coding BsiWI on both ends. Plasmid containing the dAb-Ck expression cassette was digested with BsiWI. BsiWI digested Dummy Vk domain was ligated into this to produce the dAb-extended IgG light chain, with a linker of TVAAPS' between the two variable domains.

An identical strategy was followed to produce the dAb-extended IgG heavy chain where the PCR amplified Dummy VH domain with Nhel ends was ligated into an
Nhel digested dAb heavy chain in between the dAb DOM15-26 and CH1 (Figure 51), with a linker of 'ASTKGPS' between the two variable domains. This is designated DMS2090 and has the sequence set out in SEQ ID NO: 163 (DNA sequence SEQ ID NO: 162). This was paired with the light chain set out in SEQ ID NO: 77 (DNA sequence SEQ ID NO: 171).

A second heavy chain was constructed in the same way but using the dAb DOM15-26-593. This is designated DMS2091, and has the sequence set out in SEQ ID NO: 76 (DNA sequence SEQ ID NO: 172). This was paired with the light chain set out in SEQ ID NO: 77 (DNA sequence SEQ ID NO: 171).

Sequence verified clones were selected and large scale DNA preparations were made using Qiagen Maxi or Mega Prep Kits following the manufacturer's protocols. The resulting construct was expressed in mammalian cells using transient transfection techniques by co-transfection of light and heavy chains.

**12.2 Purification and SEC analysis of the Dual Targeting anti-VEGF/anti-IL1R1 mAbdAb**

Both anti-IL1 R1/anti-VEGF dAb-extended IgG molecules were purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis for DMS2090 is shown in Figure 52, and for DMS2091 is shown in Figure 53. Both purified samples show non-reduced samples running at 190kDa whilst the reduced samples show two bands running at 35 and 60kDa corresponding to dAb-extended light chain and heavy chains respectively.

For size exclusion chromatography (SEC) analysis the anti-VEGF/anti-IL1 R1 dAb-extended-IgG was applied onto a Superdex-200 10/30 HR column (attached to an Akta Express FPLC system) pre-equilibrated and running in PBS at 0.5ml/min. The SEC profiles for DMS2090 (Figure 54) and DMS2091 (Figure 55) both show a single species running as a symmetrical peak.

**12.3 Binding Affinities of the Dual Targeting anti-VEGF/anti-IL1R1 mAbdAb**

Binding affinities to VEGF and IL1 R1 were determined as described in methods 12 and 15 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-VEGF potency (Figure 57) of DMS2090 was calculated to be 158.4pM whilst the control, an anti-VEGF mAb gave an EC50 value of 689.2pM. Anti-VEGF potency (Figure 56) of DMS2091 was calculated to be 55pM whilst the control, an anti-VEGF mAb gave an EC50 value of 766pM.
In the anti-IL1 R1 bioassay the potency of DMS2090 (Figure 58) was 32pM whilst an anti-IL1 R1 control mAb produced an EC50 of 35pM. The potency of DMS2091 (Figure 59) was 17.47pM whilst an anti-IL1-R1 control mAb produced an EC50 of 35.02pM.

In conclusion, assay data shows that example 12, a dual targeting anti-IL1 R1/anti-VEGF dAb-extended IgG is potent against both antigens.

12.4 Rat PK of the Dual Targeting anti-VEGF/anti-IL1R1 mAb

This molecule was tested for its in vivo pharmacokinetic properties in the rat. The anti-IL1 R1/anti-VEGF dAb-extended IgG A was administered i.v. to three rats, and serum samples collected over a period of 7 days (168 hours). The concentration of drug remaining at various time points post-dose was assessed by ELISA against both IL1 R1 & VEGF. The results are shown in Figure 127

The PK parameters are shown in Table 17.3

Example 13

13.1 Generation of a Triple Targeting anti-TNF/anti-VEGF/anti-EGFR mAb

A triple targeting mAb was constructed using standard molecular biology techniques and following a strategy of insertion of mAb V domain coding regions in between dAb and constant regions of both chains.

For the light chain, the anti-EGFR dAb DOM16-39-542 was previously cloned into an expression cassette with Sail and BsiWI sites (Figure 15) to produce a dAb-Ck chain. To produce the mAbdAb light chain, the mAb VL region was amplified by PCR with primers coding BsiWI on both ends. Plasmid containing the dAb-Ck expression cassette was digested with BsiWI. BsiWI digested mAb VL domain was ligated into this to produce the mAbdAb light chain, resulting in a linker of TVAAPS' between the two variable domains.

An identical strategy was followed to produce the mAbdAb heavy chain where the PCR amplified mAb VH region with Nhel ends was ligated into an Nhel digested dAb
heavy chain vector in between the dAb (DOM15-26) and CH1 (Figure 60), resulting in a linker of 'ASTKGPS' between the two variable domains.

Sequence verified clones (amino acid SEQ ID NO: 78 and 79 for heavy and light chains respectively) were selected and large scale DNA preparations were made using Qiagen Mega Prep Kits following the manufacturer’s protocols. mAbdAbs were expressed in mammalian cells using transient transfection techniques by co-transfection of light and heavy chains.

13.2 Purification of the Triple Targeting anti-TNF/anti-VEGF/anti-EGFR mAbdAb

The anti-TNF/anti-VEGF/anti-EGFR mAbdAb was purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis (figure 61) of the purified sample shows non-reduced sample running at 190kDa whilst reduced sample shows two bands running at 35 and 60kDa corresponding to dAb-extended light chain and heavy chains respectively.

13.3 Binding Affinities of the Triple Targeting anti-TNF/anti-VEGF/anti-EGFR mAbdAb

Binding affinities to VEGF, EGFR and TNF were determined as described in methods 12, 13 and 14 respectively. Assay data were analysed using GraphPad Prism.

Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-VEGF potency (Figure 62) of this mAbdAb was calculated to be 1.885mM whilst the control, an anti-VEGF mAb gave an EC50 value of 0.145mM.

In the anti-TNF bioassay (Figure 63) the potency was 87pM whilst an anti-TNF control mAb produced an EC50 of 104pM. In the anti-EGFR assay (Figure 64) the triple targeting mAbdAb produced -20% inhibition at ~300nM. Whilst EC50 values were calculated for VEGF and TNF binding, for EGFR binding a full curve was not produced to calculate an EC50 value.

Example 14: IGF-1R/VEGF mAbdAb

14.1 Construction of IGF-1R/VEGF mAbdAb

Anti IGF-1 R variable heavy and variable light gene sequences were originally built de novo from PCR of overlapping oligonucleotides. These regions were fused to human IgGl or kappa constant regions in a mammalian expression vector using standard molecular biology techniques. The gene sequence for an anti VEGF domain antibody was likewise constructed by PCR using overlapping oligonucleotides and fused to the
3' end of either the heavy or light chain genes of the anti IGF-1R components described above. The fusion incorporated either a two amino acid (GS) linker or an 8 amino acid (TVAAPSGS) linker between the antibody and the domain antibody components. Antibody heavy and light chains were also constructed without the domain antibody and linker sequences. Sequence verified clones were selected for large scale DNA preparations using Endofree Qiagen Maxiprep kit following the manufacturer's protocols.

In sequences SEQ ID NO: 108, 109, 111 and 112, the position of the linker sequence between the antibody and domain antibody is underlined. Alternative variants could be constructed by removing the linker entirely or by using different linkers. Examples of other suitable linkers are provided in SEQ ID NO: 6 and 8 to 11. Table 18 provides a list of the antibodies constructed and expressed.

Example 14.2: Expression, purification and SEC profile of IGF-1R/VEGF mAbdAb

Combinations of the heavy and light chain vectors expressed in transient transfections of HEK293-6E. Briefly, 50 ml of HEK293-6E cells at 1.5x10⁵ cells/ml were transfected with 25μg of heavy and 25μg of light chain plasmid previously incubated with 293fectin reagent (Invitrogen # 51-0031). Cells were placed in a shaking incubator at 37°C, 5% CO₂, and 95% relative humidity. After 24 hours, tryptone feeding media was added and the cells grown for a further 72 hours.

Supernatant was harvested by centrifugation followed by filtration using a 0.22μm filter. The expressed protein was purified using a Protein A sepharose column and dialysed into PBS. Purified protein was analysed by size exclusion chromatography (SEC) and is shown in Figure 65.
An IGF-1 R antibody (HOLO) was used as a comparator in the following assays. This molecule has the heavy chain sequence set out in SEQ ID NO: 110, and the light chain sequence set out in SEQ ID NO: 113.

Another mAbdAb with irrelevant specificity was used as a comparator in the following assays. This molecule has the heavy chain sequence set out in SEQ ID NO: 87, and the light chain sequence set out in SEQ ID NO: 13 and is designated BPC1601.

**Example 14.3: IGF-1R Binding ELISA**

A binding ELISA was carried out to test the binding of the purified anti-IGF-1 R/VEGF mAbdAbs to IGF-1 R. Briefly, ELISA plates coated with anti-polyhistidine (AbCam AB9108) at 1µg/ml and blocked with blocking solution (4% BSA in Tris buffered saline) were loaded with 400ng/ml recombinant human IGF-1 R-his tag (R&D Systems 305-GR) in PBS. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Various concentrations of the purified mAbdAbs were added as well as an anti IGF-1 R monoclonal antibody (HOLO) and an irrelevant mAbdAb (BPC1601), diluted in blocking solution. The plate was incubated for 1 hour at room temperature before washing in TBST. Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H2SO4. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.

The results of the binding ELISA are presented in Figure 66 and confirm that all the IGF1 R-VEGF mAbdAb variants tested (BPC1 603-1 606) show binding to IGF-1 R at levels comparable to the anti-IGF-1 R antibody HOLO. EC50 values were calculated using Cambridgesoft Bioassay software and are as follows: HOLO (0.1797 µg/ml), BPC1603 (0.1602 µg/ml), BPC1604 (0.1160 µg/ml), BPC1605 (0.1975 µg/ml), BPC1606 (0.1403 µg/ml). The irrelevant control bispecific antibody BPC1601 showed no detectable binding to IGF-1 R.

**Example 14.4: VEGF Binding ELISA**

A binding ELISA was carried out to test the binding of the purified anti IGF-1 R/VEGF bispecific antibodies to VEGF. ELISA plates were coated with recombinant human VEGF (GSK) at 400ng/ml in PBS and then blocked in blocking solution (4% BSA in TBS). Various concentrations of the purified mAbdAbs diluted in blocking solution were added and mAbdAb BPC1601 was included as a negative control. The plate was incubated for 1 hour at room temperature before washing in TBST. Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 40 minutes at room temp before washing in TBST. The plate was
developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.

The results of the binding ELISA are presented in Figure 67 and confirm that all four anti-IGF-1 R/VEGF mAbdAbs (BPC1603-1 606) can bind to immobilised VEGF. The apparent lower binding activity of BPC1605 and BPC1606 may be attributable to interference between the domain antibody (located at the C-terminus of the light chain) and the detection antibody. EC50 values were calculated using Cambridgesoft Bioassay software and are as follows: BPC1603 (0.044 µg/ml), BPC1604 (0.059 µg/ml), BPC1605 (0.571 µg/ml). It was not possible to calculate an accurate EC50 value for BPC1606 due to the lower response values. The anti-IGF-1 R antibody HOLO and the irrelevant control mAbdAb BPC1601 showed no detectable binding to VEGF.

**Example 14.5: Kinetics of binding to VEGF**

A mouse monoclonal against human IgG (Biacore BR-1 008-39) was immobilised by primary amine coupling to a CM5 biosensor chip. The antibody constructs were captured using this surface. After capture VEGF was passed over the surface which was then regenerated using 3M MgCl₂. The concentrations of VEGF used to generate kinetics were 256, 64, 16, 4, 1 and 0.25nM, with a buffer only injection over the captured surface used for double referencing. The experiments were carried out on the Biacore T100 machine, using 1x HBS-EP buffer (BR-1 006-69) at 25°C. The data were fitted to the 1:1 model inherent to the machine in its analysis software. The data shown in Table 19 is from two independent experiments.

**Example 14.6: Inhibition of VEGF binding to receptor**

The activity of the mAbdAbs was measured using a VEGF receptor binding assay as described in Method 12. The IC50s obtained in this assay for inhibition of the binding of VEGF to VEGFR2 are:

BPC1603 (0.037nM)
BPC1604 (0.010nM)
BPC1605 (0.167nM)
BPC1606 (0.431 nM)

These results confirm that all four antigen binding constructs inhibit ligand binding to receptor.
Example 14.7: Inhibition of IGF-1R receptor phosphorylation
3T3/LISN c4 cells were plated at a density of 10 000 cells/well into 96 well plates and incubated overnight in complete DMEM (DMEM-Hepes modification +10%FCS). Purified mAbdAbs were added to the cells and incubated for 1 hour. rhIGF-1 was added to the treated cells to achieve a final concentration of 50ng/ml and incubated for a further 30 mins to stimulate receptor phosphorylation. The media was aspirated and then the cells lysed by the addition of RIPA lysis buffer (150mM NaCl, 50mM TrisHCl, 6mM Na Deoxycholate, 1% Tween 20) plus protease inhibitor cocktail (Roche 11 697 498 001). The plate was frozen overnight. After thawing, lysate from each well was transferred to a 96 well ELISA plate pre-coated with an anti IGF-1 R capture antibody 2B9 (GSK) at 2μg/ml and blocked with 4%BSA/TBS. The plate was washed with TBST (TBS+0.1%Tween 20) and a Europium labelled anti Phosphotyrosine antibody (PerkinElmer DELFIA Eu-NI PT66) diluted 1/2500 in 4%BSA/TBS was added to each well. After 1 hour incubation the plate was washed and DELFIA Enhancement (PerkinElmer 1244-105) solution added. After 10 min incubation the level of receptor phosphorylation was determined using a plate reader set up to measure Europium time resolved fluorescence (TRF).

The results of the experiment are presented in Figures 68 and 69. The results confirm that the mAbdAbs BPC1 603-1 606 can inhibit IGF-I mediated receptor phosphorylation at levels comparable to the anti-IGF-1 R monoclonal antibody H0L0. an irrelevant antibody (labelled as IgGI, Sigma 15154) showed no activity in this assay.

Example 15 anti-CD20/IL-13 antigen binding protein

Example 15.1: Molecular biology
The mammalian expression vectors encoding the heavy and light chain sequences of an anti-CD20 mAb set out in SEQ ID NO: 117 and 120 were constructed de novo using a PCR based approach and standard molecular biology techniques. Bispecific anti-CD20mAb-anti-IL13dAb heavy and light chains were constructed by cloning the sequences encoding anti-CD20 mAb heavy and light variable regions into mammalian expression vectors containing human antibody constant regions fused to an anti-human IL-13 domain antibody (DOM1 0-53-474).

The mAbdAb expression constructs were transfected into CHOElα cells. The supernatant was harvested and then the antibody purified using immobilised Protein A and quantified by reading absorbance at 280nm. The mAbdAbs (and the anti-CD20 control mAb) constructed and tested are listed in Table 20.
Example 15.2: Kinetics of binding to human IL-13

The binding affinity of mAbdAb constructs for human IL-13 were assessed by BIAcore™ analysis. Analyses were carried out anti-human IgG capture. Briefly, Anti-human IgG (Biacore BR-1 008-39) was coupled onto a CM5 chip by primary amine coupling. MAbdAb constructs were then captured onto this surface and human IL-13 (made and purified at GSK) passed over at defined concentrations. The surface was regenerated back to the Anti-human IgG surface using 3M MgCl₂. This treatment did not significantly affect the ability to capture antibody for a subsequent IL-13 binding event. The runs were carried out at 25°C using HBS-EP buffer, on the BIAcore™ T100 machine. Data were analysed using the evaluation software in the machine and fitted to the 1:1 binding model. The results of the analysis are presented in Table 48, confirming that for all mAbdAb constructs, the kinetics of binding to IL-13 are comparable.

The ADCC assay was based on the published method of Boyd et al. (1995) J. Imm. Meth. 184:29-38. Briefly, Raji cells (targets) were labelled with Europium as follows.

Cells were harvested, counted and prepared to a final density of 1x10^7 in a 15ml falcon tube, wash once with Hapes buffer (50mM HEPES, 83mM NaCl, 5mM KCl, 2mM MgCl_2·H_2O, pH7.4). The cells were pelleted and 1ml of ice cold Europium labelling buffer (HEPES buffer plus 600µM EuCl_3, 3mM DTPA and 25mg/ml Dextran sulphate) was added to each tube. The cell suspension was flicked vigorously at the start of the labelling and then every 10 minutes during the 30 minute incubation period on ice. 10ml ice cold repair buffer (Hapes buffer containing 294mg/l CaCl_2·2H_2O, 1.8g/l D-Glucose, pH7.4) was added and the cells incubated on ice for a further 10 minutes. The cells were then centrifuged, the supernatant decanted and washed twice with repair buffer and then once with complete medium. The labelled cells were then counted and resuspended in serum free medium at 2x10^5 cells/ml and stored on ice.

Human purified blood mononuclear cells (PBMCs or effector cells) were prepared as follows. 150mls of whole blood was centrifuged at 2000rpm for 10mins to remove the serum. The cells were the diluted to twice the original volume with PBS (Invitrogen/Gibco, #14190). Accuspin density gradient tubes (Sigma, #A2055-10EA) were prepared by adding 15ml lymphoprep (Axis shield, #NYC114547) and centrifuged for 1min at 1500rpm. 25ml of blood suspension was added to the density gradient tubes and centrifuged for 20min at 2500rpm with the centrifuge brake off. The top 10ml of supernatant was discarded. The remainder (including the "buffy" layer) was poured into a clean tube, topped up with PBS and centrifuged at 1500rpm for 5mins. The supernatant was discarded, the cell pellets pooled, wash once in RPMI medium, recentrifuged and counted. Effector cells at were prepared at 5x10^6/vml in serum free RPMI medium.

The assay plates were set up in 96-well round bottom plates (Nunc 96 maxisorb plate, #735-0199) as follows. Antibody dilutions were made in serum free RPMI medium at a starting concentration of approximately 12µg/ml and eleven further 3-fold dilutions. Using the plate layout below, 50µl antibody sample was added to the appropriate wells (rows B-G only), allowing 6 replicates per dilution). 50µl RPMI medium was added to all wells in rows A and H. 50µl of RPMI medium was added to all wells in plates labelled medium. 50µl recombinant human IL-13 diluted in RPMI 50µl medium.
medium to 4µg/ml (1µg/ml final concentration, GSK in-house material) was added to all wells in plates labelled +IL13. All plates were incubated at 4°C for minimum 30 minutes. 50µl of Europium labelled target cells were added to all plates. 20µl of a 10X triton was added to all wells in row H on all plates. Plates were incubated 4°C for a minimum of 30 minutes. 50µl RPMI medium was added to all wells in columns labelled targets alone. 50µl PBMCs was added to all wells in columns labelled effector:targets to give a 25:1 ratio. The plates were centrifuged at 1500rpm for 3mins and incubated at 37°C for 3-4hrs. 200µl of enhancement solution (Wallac/Perkin Elmer, Catalogue# 1244-105) was added to each well of a nunc immunosorbtant ELISA plates (one ELISA plate for each assay plate). 20µl of supernatant was transferred from assay plate to ELISA plate. The ELISA plates were incubated at room temperature on plate shaker for a minimum 30 minutes or stored over night at 4°C. Europium release is measured using time-delayed fluorimetry (Wallac Victor plate reader). Spontaneous lysis = measurement of Europium released from cells and medium alone. Maximum lysis = non-specific lysis of target cells by addition of Triton-X100 (non-ionic detergent).

The ADCC assay was performed on two separate occasions using two different donor PBMCs. The results from one representative assay are presented in Figures 70 and 71. In addition, a similar ADCC assay using a shorter dose range was performed on a separate occasion using different donor PBMCs. The results from this assay are presented in Figure 72 and 73.

**Example 15.4: CDC assay with anti-CD20/IL-13 bispecific antibody**

WEIN cells (targets) were labelled with Europium as follows. Briefly, cells were harvested, counted and prepared to a final density of 1x10^7 in a 15ml falcon tube, wash once with Hepes buffer (50mM HEPES, 83mM NaCl, 5mM KCl, 2mM MgCl2.H2O, pH7.4). The cells were pelleted and 1 ml of ice cold Europium labelling buffer (HEPES buffer plus 600µM EuCl3, 3mM DTPA and 25mg/ml Dextran sulphate) was added to each tube. The cell suspension was flicked vigorously at the start of
the labelling and then every 10 minutes during the 30 minute incubation period on ice. 10ml ice cold repair buffer (Hepes buffer containing 294mg/l CaCl₂, 2H₂O, 1.8g/l D-Glucose, pH7.4) was added and the cells incubated on ice for a further 10 minutes. The cells were then centrifuged, the supernatant decanted and washed twice with repair buffer and then once with complete medium. The labelled cells were then counted and resuspended in serum free medium at 2x10⁵ cells/ml and stored on ice.

Serum was removed from whole blood collected from in house donors by centrifugation. Half of the sample was inactivated by heat treatment at 56°C for 30mins. Antibodies samples were diluted in serum free RPMI medium, starting a 12µg/ml with five further 3-fold dilutions. 50µl antibody sample was added to appropriate wells in rows B-G only (as per the plate layout below). 50µl RPMI medium was added to all wells in columns 1 to 6. Where indicated, 50µl recombinant human IL-13 (at 4µg/ml in RPMI medium) was added to all wells in columns 7 to 12. The plates were incubated at 4°C for a minimum 30 minutes. 50µl of Europium labelled target cells were added to all the plates and the plates incubated at 4°C for minimum of 30 minutes. 50µl of serum (active or heat-inactivated) was added to the appropriate wells (see plate layout below). The plates were incubated at 37°C incubator for 2-3hrs, after which time the plates were centrifuged at 1500rpm for 3mins. 200µl of enhancement solution (Wallac/Perkin Elmer, Catalogue* 1244-105) was added to each well of a Nunc immunosorbant ELISA plates (one ELISA plate for each assay plate). 20µl of supernatant was transferred from assay plate to ELISA plate. The ELISA plates were incubated at room temperature on plate shaker for a minimum 30 minutes or stored over night at 4°C. Europium release is measured using time-delayed fluorimetry (Wallac Victor plate reader). Spontaneous lysis = measurement of Europium released from cells and medium alone. Maximum lysis = non-specific lysis of target cells by addition of Triton-X100 (non-ionic detergent).

The CDC assay was performed on three separate occasions using three different donor sera. The results from one representative assay are presented in Figures 74.
and 75 and show that the CDC activity of the antibody samples is comparable in the absence of IL-13. In the presence of excess IL-13, the CDC activity of antibody samples BPC1401 and BPC1402 (domain antibody fused to the heavy chain) is reduced whilst the CDC activity of BPC1403 and BPC1404 (domain antibody fused to the light chain) is largely unaffected by the presence of IL-13.

**Example 16**

**16.1 Design and construction of antigen binding proteins comprising epitope binding domains composed of alternative scaffolds**

Five alternative scaffolds, listed below, were combined with monoclonal antibodies to provide mAb-alternative scaffold bispecific molecules:

- anti VEGF tear lipocalin (TLPC)
- anti HER2 Affibody (AFFI)
- anti HER2 DARPin (DRPN)
- anti hen egg white lysozyme (NARV)
- anti-RNaseA Camelid VHH

The protein sequences of TLPC (for further information see US2007/0224633), AFFI (for further information see WO2005003156A1), DRPN (for further information see Zahnd, C. et al. (2007), J. Mol. Biol., 369, 1015-1028) and NARV (for further information see US20050043519A) were reverse-translated to DNA and codon optimised. A BamHI site at the N-terminus and EcoR1 site at the C-terminus were included on each of these four alternative scaffolds to facilitate cloning.

DNA fragments encoding the four final alternative scaffold DNA sequences were constructed de novo using a PCR-based strategy and overlapping oligonucleotides. The TLPC, AFFI and DRPN PCR products were cloned into mammalian expression vectors containing the heavy chain of HOLO, an anti-hiGF-1 R antibody. The resulting DNA sequences encode the alternative scaffolds fused onto the C-terminus of the heavy chain via a TVAAPSGS linker or GS linker. The NARV PCR product was cloned into mammalian expression vectors containing DNA encoding the heavy chain of Pascolizumab (an anti-IL-4 antibody). The resulting DNA sequence encodes the NARV fused onto the C-terminus of the heavy chain via a GS linker.

An anti-RNase A camelid VHH DNA sequence was modified by PCR to include a BamHI site at the 5' end and an EcoR1 site at the 3' end in order to facilitate cloning. The PCR product was cloned into mammalian expression vectors containing the heavy chain of Pascolizumab, an anti-IL4 antibody. The resulting DNA sequence
encodes a camelid VHH fused onto the C-terminus of the heavy chain via a GS linker.

Table 21 below is a summary of the antigen binding proteins that have been constructed.

Expression plasmids encoding the heavy and light chains of the antigen binding proteins set out in Table 21 were transiently co-transfected into HEK 293-6E cells.
using 293fectin (Invitrogen, 12347019). A tryptone feed was added to each of the cell cultures the same day or the following day and the supernatant material was harvested after about 2 to 6 days from initial transfection. The antigen binding protein was purified from the supernatant using a Protein A column before being tested in binding assays.

16.2: rhIGF-1 R Binding ELISA

96-well high binding plates were coated with 1µg/ml of anti-his-tag antibody (Abeam, ab9108) in PBS and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200 µL of blocking solution (5% BSA in DPBS buffer) was added in each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. 0.4 µg/ml of rhIGF-1 R (R&D systems) was added to each well at 50 µl per well. The plates were incubated for an hour at room temperature and then washed. The purified antigen binding proteins/antibodies were successively diluted across the plates in blocking solution. After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1µg/mL and 50µl was added to each well. The plates were incubated for one hour. After another wash step, 50 µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25 µl of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figures 76, 78 and 80 show the ELISA results and confirm that antigen binding proteins BPC1803 - BPC1808 bind to recombinant human IGF-1 R. The anti-IGF-1 R monoclonal antibody HOLO also showed binding to recombinant human IGF-1 R whereas the negative control antibody (sigma 15154) showed no binding to IGF-1 R.

16.3: VEGF Binding ELISA

96-well high binding plates were coated with 0.4 µg/mL of hVEGF165 (R&D Systems) and incubated at +4°C overnight. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200 µL of blocking solution (5% BSA in DPBS buffer) was added to each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. The purified antigen binding proteins/antibodies were successively diluted across the plates in blocking solution. After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1µg/mL and 50µL was added to each well. The plates were incubated for one hour. After another wash step, 50 µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25 µL of 3M sulphuric acid. Absorbance was read at 490nm using
the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 77 shows the results of the VEGF binding ELISA and confirms that bispecific antibodies BPC1803 and BPC1804 bind to human VEGF. An anti VEGF bispecific antibody (BPC1603) was used as a positive control in this assay and showed binding to VEGF. In contrast the anti-IGF-1 R monoclonal antibody HOLO showed no binding to human VEGF.

16.4: HER2 Binding ELISA

96-well high binding plates were coated with 1µg/mL of HER2 (R&D Systems) and incubated at +4°C overnight. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200 µL of blocking solution (5% BSA in DPBS buffer) was added to each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. The purified antigen binding proteins/antibodies were successively diluted across the plates in blocking solution.

After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1µg/mL and 50 µL was added to each well. The plates were incubated for one hour. After another wash step, 50 µL of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25 µL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figures 79 and 81 show the results of the HER2 binding ELISA and confirms that the antigen binding proteins BPC1805, BPC1806, BPC1807 and BPC1808 bind to recombinant human HER2. Herceptin was used as a positive control in this assay and showed binding to HER2. In contrast the anti-IGF-1 R monoclonal antibody HOLO showed no binding to human HER2.

16.5: IL-4 Binding ELISA

96-well high binding plates were coated with 5µg/ml of human IL-4 in PBS and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200 µL of blocking solution (5% BSA in DPBS buffer) was added in each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. The purified antigen binding proteins/antibodies were successively diluted across the plates in blocking solution.

After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was diluted in blocking solution to 1µg/mL and 50 µL was added to each well. The plates were incubated for one hour. After another wash step, 50 µL of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the
reaction was stopped 15 minutes later by addition of 25µL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 82 shows the results of the ELISA and confirms that antigen binding protein BPC1809 binds to human IL-4 at levels comparable to the anti IL-4 monoclonal antibody, Pascolizumab. The negative control antibody (Sigma 15154) showed no binding to IL-4.

Figure 84 shows the results of the ELISA and confirms that antigen binding protein BPC1816 binds to human IL-4 at levels comparable to the anti IL-4 monoclonal antibody, Pascolizumab. The negative control antibody (Sigma 15154) showed no binding to IL-4.

16.6: RNAse A Binding ELISA

50µL of 1µg/mL RNAse A (Qiagen, 19101) that had been diluted in PBS was added to each well of a 96 well Costar plate. The plate was incubated for 2 hours at room temperature then washed with PBST before addition of 200µL of 4% BSA/PBS block to each well. The plate was incubated for an hour and washed before addition of the samples. Purified antibodies and antigen binding protein BPC1809 were added at a concentration of 2µg/mL in wells of column 1 then serially diluted 1 in 2 across the plate in block. The plate was incubated for an hour then washed. 50µl/well of Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was added at a 1 in 1000 dilution. The plate was incubated for an hour then washed. 50µL of OPD was added to each well and the reaction was stopped with 3M sulphuric acid after 15-30 minutes. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 83 shows the results of the RNAse A binding ELISA and confirms that purified human monoclonal antibody-camelid VHH bispecific antibody BPC1809 shows binding to RNAse A. In contrast both the IL-4 monoclonal antibody Pascolizumab and the negative control (sigma 15154) showed no binding to RNAse A.

16.7: HEL Binding ELISA

A 96-well high binding plate was coated with 5µg/ml of HEL (Hen Egg Lysozyme, Sigma L6876) in PBS and stored overnight at 4°C. The plate was washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200µL of blocking solution (5% BSA in DPBS buffer) was added in each well and the plate was incubated for at least 1 hour at room temperature. Another wash step was then performed. The purified antibodies were successively diluted across the plate in blocking solution. After 1 hour incubation, the plate was washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was diluted in blocking solution to
1 µg/mL and 50 µl was added to each well. The plate was incubated for one hour. After another wash step, 50 µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25 µl of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 85 shows the results of the HEL binding ELISA and confirms that purified human monoclonal antibody - NAR V bispecific antibody BPC1816 binds to HEL. In contrast the IL-4 monoclonal antibody Pascolizumab showed no binding to HEL.

**Example 17**

**17.1 Design and construction of antigen-binding proteins comprising epitope binding domains composed of adnectin**

CT01 adnectin is specific for VEGFR2 (for further information see WO2005/056764). The CT01 adnectin protein sequence was reverse-translated to DNA and codon optimised. A BamHI site at the N-terminus and EcoR1 site at the C-terminus were included to facilitate cloning.

DNA fragments encoding the final CT01 DNA sequence were constructed de novo using a PCR-based strategy and overlapping oligonucleotides. The PCR product was cloned into mammalian expression vectors containing the heavy chain of HOLO (an anti-hIGF-1 R antibody) allowing the adnectin to be fused onto the C-terminus of the heavy chain via either a GS linker or a TVAAPSGS linker. Protein sequences of the heavy and light chains of the IGF-1 R - VEGFR2 bispecific are given in SEQ ID numbers 124, 113 and 133.

Another adnectin protein sequence coding for an anti-TNF-α adnectin (for further information see US200801 39791 ) was reverse translated to DNA, codon optimised and modified to include terminal BamHI and EcoR1 sites before being constructed using the overlapping oligonucleotide PCR method described previously. The PCR product was cloned into mammalian expression vectors containing DNA encoding the heavy chain of Pascolizumab (an anti-IL-4 antibody) allowing DNA encoding the anti-TNF-α adnectin to be fused onto the C-terminus of the heavy chain via either a GS linker or a TVAAPGS linker. Protein sequences of the heavy and light chains of the IL-4 - TNF-α bispecific are given in SEQ ID NO: 146, 147 and 15.

Antigen binding proteins using the TNF-α specific adnectin fused at the C-terminus of the heavy chain of an IL-13 monoclonal antibody have also been designed.

Example protein sequences are given in SEQ ID's 134, 13 and 135. In addition, bispecific molecules based on the fusion of CT01 at either the C-terminus or the N-terminus of the heavy or light chain of anti-EGFR antibodies Erbitux and IMC-1 F8 have been designed. Examples of protein sequences which have been designed are given in SEQ ID NO: 136-145.
Of these example sequences, a number were constructed. DNA sequences encoding SEQ ID NO 136 (CT01 fused onto the C-terminus of the Erbitux heavy chain), SEQ ID NO 144 (CT01 fused onto the N-terminus of Erbitux heavy chain) and SEQ ID NO 138 (CT01 fused onto the C-terminus of the Erbitux light chain) were constructed. All three sequences were constructed using PCR-based cloning methods and cloned into mammalian expression vectors. Table 22 below is a summary of the antigen binding proteins that have been designed and/or constructed.

Expression plasmids encoding the heavy and light chains of BPC1801, BPC1802, BPC1822, BPC1823, BPC1812, BPC1813 and BPC1818 were transiently co-transfected into HEK 293-6E cells using 293fectin (Invitrogen, 12347019). A tryptone feed was added to the cell culture the same day or the following day and the supernatant material was harvested after about 2 to 6 days from initial transfection. In some instances the supernatant material was used as the test article in binding assays. In other instances, the antigen binding protein was purified using a Protein A column before being tested in binding assays.

### 17.2: rhlGF-1 R Binding ELISA

96-well high binding plates were coated with 1µg/ml of anti-his-tag antibody (Abeam, ab9108) in PBS and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200µL of blocking solution (5% BSA in DPBS buffer) was added in each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. 0.4µg/mL of rhlGF-1 R (R&D systems) was added to each well at 50µL per well. The plates were incubated for an hour at room temperature and then washed. The purified antigen binding proteins/antibodies were successively diluted across the plates in blocking solution. After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1µg/mL and 50µL was added to each well. The plates were incubated for one hour. After another wash step, 50µl of OPD (o-phenylenediamine dihydrochloride)
SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25μL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 86 shows the results of the IGF-1 R binding ELISA and confirms that purified human monoclonal antibody-adnectin bispecific antibodies (BPC1801 and BPC 1802) bind to recombinant human IGF-1 R at levels comparable to the anti-IGF-1 R monoclonal antibody HOLO. The negative control antibody (Sigma 15154) showed no binding to IGF-1 R.

17.3: VEGFR2 Binding ELISA

96-well high binding plates were coated with 0.4μg/mL of VEGFR2 (R&D Systems) and incubated at +4°C overnight. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200μL of blocking solution (5% BSA in DPBS buffer) was added to each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. The supernatants or purified antibodies were successively diluted across the plates in blocking solution. After 1 hour incubation, the plate was washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1μg/mL and 50μL was added to each well. The plates were incubated for one hour. After another wash step, 50μL of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25μL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 87 shows the results of the VEGFR2 binding ELISA and confirms that purified human monoclonal antibody-adnectin bispecific antibodies (BPC1801 and BPC1802) bind to recombinant human VEGFR2. In contrast the anti-IGF-1 R monoclonal antibody HOLO showed no binding to human VEGFR2.

Figure 172 shows the results of the VEGFR2 binding ELISA and confirms that antigen binding proteins BPC1818 and BPC1813 bind to recombinant human VEGFR2. In contrast Erbitux showed no binding to human VEGFR2. For the antigen binding proteins BPC1813 and BPC1818, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 172 is represented as a dilution factor of the neat supernatant material. For Erbitux, purified material was used in the assay at the starting concentration of 2μg/ml, which is equivalent to dilution factor of 1 in Figure 172.

Figure 175 shows the results of the VEGFR2 binding ELISA and confirms that antigen binding protein BPC1812 binds to recombinant human VEGFR2. In contrast
Erbitux and the negative control Sigma IgG 15154 antibody showed no binding to human VEGFR2. For the antigen binding protein BPC1812, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 175 is represented as a dilution factor of the neat supernatant material. For Erbitux and Sigma IgG 15154 purified material was used in the assay at the starting concentration of 2µg/ml, which is equivalent to dilution factor of 1 in Figure 175.

17.4: IL-4 Binding ELISA

96-well high binding plates were coated with 5µg/ml of human IL-4 in PBS and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200µL of blocking solution (5% BSA in DPBS buffer) was added in each well and the plates were incubated for at least 1 hour at room temperature. Another wash step was then performed. The supernatant or purified antibodies/antigen binding proteins were successively diluted across the plate in blocking solution. After 1 hour incubation, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was diluted in blocking solution to 1µg/mL and 50µL was added to each well. The plates were incubated for one hour. After another wash step, 50µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25µL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 88 shows the results of the IL-4 binding ELISA and confirms that human monoclonal antibody-adnectin bispecific antibodies (BPC1823 and BPC 1822) bind to recombinant human IL-4. The positive control anti-IL-4 monoclonal antibody Pascolizumab showed binding to IL-4 and the negative control antibody (Sigma 15154) showed no binding to IL-4.

The HEK transfection for this experiment was repeated to obtain supernatant material with a higher antibody concentration. Figure 88b shows binding of this higher concentration supernatant human monoclonal antibody-adnectin bispecific antibody (BPC1823) to human IL-4 as determined by ELISA.

For the antigen binding proteins BPC1823 and BPC1822, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 88 and 88b is represented as a dilution factor of the neat supernatant material. For Pascolizumab and the negative control antibody (Sigma 15154), purified material was used in the assay and the starting concentration of 1µg/ml, which is equivalent to dilution factor of 1 in Figure 88 and 88b.
17.5: TNF-α Binding ELISA

A 96-well high binding plate was coated with 0.4µg/ml of recombinant human TNFα (RnD Systems 210-TA-050/CF) in PBS and stored overnight at 4°C. The plate was washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200µl of blocking solution (5% BSA in DPBS buffer) was added in each well and the plate was incubated for at least 1 hour at room temperature. Another wash step was then performed. The supernatant or purified antibodies were successively diluted across the plate in blocking solution. After 1 hour incubation, the plate was washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was diluted in blocking solution. The plate was incubated for one hour. After another wash step, 50µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 15 minutes later by addition of 25µl of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 89 shows the results of the TNF-α binding ELISA and confirms that human monoclonal antibody-adnectin bispecific antibodies (BPC1823 and BPC1822) bind to recombinant human TNF-α. In contrast the anti-IL-4 monoclonal antibody Pascolizumab showed no binding to recombinant human TNF-α.

The HEK transfection for this experiment was repeated to obtain supernatant material with a higher antibody concentration. Figure 89b shows binding of this higher concentration supernatant human monoclonal antibody-adnectin bispecific antibody (BPC1823) to recombinant human TNF-α as determined by ELISA. The IgG control showed no binding to recombinant human TNF-α.

For the antigen binding proteins BPC1822 and BPC1823, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 89 and 89b is represented as a dilution factor of the neat supernatant material. For Pascolizumab, purified material was used in the assay at the starting concentration of 1µg/ml, which is equivalent to dilution factor of 1 in Figure 89 and 89b.

17.6: EGFR Binding ELISA

A 96-well high binding plate was coated with 0.67µg/ml of recombinant human EGFR protein in PBS and stored overnight at 4°C. The plate was washed twice with Tris-Buffered Saline with 0.05% of Tween-20. 200µl of blocking solution (5% BSA in DPBS buffer) was added in each well and the plate was incubated for at least 1 hour at room temperature. Another wash step was then performed. The antigen binding proteins/antibodies were successively diluted across the plate in blocking solution. After 1 hour incubation, the plate was washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma, A7164) was diluted in blocking
solution to 1µg/mL and 50µl was added to each well. The plate was incubated for one hour. After another wash step, 50µl of OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 25 minutes later by addition of 25µl of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 171 shows the results of the EGFR binding ELISA and confirms that bispecific antibodies BPC1818 and BPC1813 bind to recombinant human EGFR. The positive control antibody, Erbitux, also showed binding to recombinant human EGFR. In contrast the Sigma IgG 15154 showed no binding to recombinant human EGFR. For the bispecific antibodies BPC1813 and BPC1818, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 171 is represented as a dilution factor of the neat supernatant material. For Erbitux and the negative control antibody (Sigma 15154), purified material was used in the assay and the starting concentration of 2µg/ml and 1µg/ml respectively, which is equivalent to dilution factor of 1 in Figure 171.

Figure 176 shows the results of the EGFR binding ELISA and confirms that bispecific antibodies BPC1812 binds to recombinant human EGFR. The positive control antibody, Erbitux, also showed binding to recombinant human EGFR. In contrast the Sigma IgG 15154 showed no binding to recombinant human EGFR. For the bispecific antibodies BPC1812, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 176 is represented as a dilution factor of the neat supernatant material. For Erbitux and the negative control antibody (Sigma 15154), purified material was used in the assay at the starting concentration of 2µg/ml and 1µg/ml respectively, which is equivalent to dilution factor of 1 in Figure 176.

**Example 18**

*Binding activity data of IL-13/IL-4 mAbdAbs where the 'G and S' amino acid residues have been removed.*

18.1 Construction of mAbdAbs

mAbdAbs were constructed in which the G and S amino acid residues (next to the linker sequence) were removed. Expression plasmids were constructed using standard molecular biology techniques. These mAbdAbs are described in Table 23. They were cloned, then expressed in one or more of HEK293-6E cells, CHOK1 cells, or CHOELa cells, they were purified (as described in examples 1, 1.3 and 1.5 respectively) and analysed in a number of IL-13 and IL-4 activity assays.

18.2 Expression and purification
These mAbdAbs were purified and analysed by SEC and SDS PAGE. A number of purified preparations were made and the SEC and SDS PAGE data shown in Figures 90 to 98 are representative of these preparations.

18.3 Binding to human IL-4 in a direct binding ELISA
Purified PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed were tested for binding to human IL-4 in a direct binding ELISA as described in method 2 (PascoH-474, PascoH-TVAAPS-474, PascoH-ASTKG-474 and PascoH-ELQLE-474 were also tested for binding in this assay). A number of ELISA assays have been completed for these molecules, the data shown in Figure 99 is representative of these assays.

18.4 Binding to human IL-13 in a direct binding ELISA
Purified PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed were also tested for binding to human IL-13 in a direct binding ELISA as described in method 1 (PascoH-616 and PascoH-TVAAPS-616 were also tested for binding in this assay, the generation of these molecules is described in Example 19). A number of ELISA
assays have been completed for these molecules, the data shown in Figure 100 is representative of all assays.

PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed, PascoH-616 and PascoH-TVAAPS-616 all bound to human IL-13. Purified anti-human IL4 mAb alone (Pascolizumab) was included in this assay as a negative control for binding to IL-13. Purified anti-human IL13 mAb was included as a positive control for IL-13 binding. Note that the anti-IL-13 dAb alone (DOM1 0-53-474) was not tested in this assay as the dAb is not detected by the secondary detection antibody; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

18.5 Binding to cynomolgus IL-13 in a direct binding ELISA
Purified PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed, PascoH-616 and PascoH-TVAAPS-616 mAbdAbs were also tested for binding to cynomolgus IL-13 in a direct binding ELISA (as described in method 17). A number of ELISA assays have been completed for these molecules, the data shown in Figure 101 is representative of all assays.

PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed, PascoH-616 and PascoH-TVAAPS-616 all bound cynomolgus IL-13. Purified anti-human IL4 mAb alone (Pascolizumab) was included in this assay as a negative control for binding to IL-13. Purified anti-human IL13 mAb was included as a positive control for cynomolgus IL-13 binding. Note that the anti-IL-13 dAbs alone (DOM1 0-53-474 and DOM1 0-53-616) were not tested in this assay as the dAb is not detected by the secondary detection antibody; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

18.6 Biacore analysis for binding to human IL-4 and human IL-13
Purified mAbdAbs were tested for binding to human IL-4 and human IL-13 using the BIAcore™ T100 at 25°C (as described in methods 4 and 5). These data are shown in Table 24.

In experiment 1, a mAbdAb capture level of approximately 600 relative response units was achieved and six IL-13 and IL-4 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed. Only one IL-13 (256nM) and IL-4 (256nM) concentration curve was assessed for the mAbs in experiment 1.

In experiment 2, a mAbdAb a capture level of approximately 400 relative response units was achieved and six IL-4 (64nM, 16nM, 4nM, 1nM, 0.25nM and 0.0625nM) and six IL-13 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed. In experiment 2, only one IL-13 concentration curve (256nM) was assessed for the anti-IL13 mAb and five IL-4 concentration curves (64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed for Pascolizumab.
In experiment 3, a mAb or mAb capture level of approximately 700 relative response units was achieved and six IL-4 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) and six IL-13 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed.

In experiments 1 and 2, PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed, both bound IL-4 with similar binding affinities and this was approximately equivalent to the binding affinity of the anti-human IL4 mAb alone (Pascolizumab). PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed, also bound IL-13 with similar binding affinities. Note that the anti-IL-13 dAb alone (DOM1-0-53-474) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

In experiment 3, 586H-210 GS removed and 586H-TVAAPS-210 GS removed, both bound IL-13 with similar binding affinities and this was approximately equivalent to the binding affinity of the anti-human IL13 mAb. 586H-210 GS removed and 586H-TVAAPS-210 GS removed, also bound IL-4 very tightly, however this method was unable to determine the binding affinity due to positive dissociation effects and the sensitivity level of the BIAcore™ technique (*). Note that the anti-IL-4 dAb alone (DOM9-1 12-210) was not tested in this assay as the dAb cannot be captured onto
the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay.

18.7 Biacore analysis for binding to cynomolagus IL-4 and cynomolagus IL-13

Purified mAbdAbs were tested for binding to cynomolagus IL-4 and cynomolagus IL-13 using the BIAcore™ T100 at 25°C (as described in methods 24 and 23). These data are shown in Table 25. A mAbdAb capture level of approximately 600 relative response units was achieved and six IL-13 concentration curves (256, 64, 16, 4, 1, 0.25nM) and five IL-4 concentration curves (64, 16, 4, 1, 0.25nM) were assessed.

Purified mAbdAbs were also tested for binding to cynomolagus IL-4 and cynomolagus IL-13 using the BIAcore™ T100 at 25°C (as described in methods 24 and 23). These data are shown in Table 26. A mAbdAb capture level of approximately 600 relative response units was achieved and six IL13 and six IL-4 concentration curves (256, 64, 16, 4, 1 and 0.25nM) were assessed.

</table>

586H-210 GS removed and 586H-TVAAPS-210 GS removed, both bound cynomolgus IL-13 with similar binding affinities; these mAbdAbs appeared to bind IL-13 more potently than the anti-human IL13 mAb, however in the case of the mAb only one concentration curve was completed which is inherently less accurate than a full concentration range assessment. 586H-210 GS removed and 586H-TVAAPS-210 GS removed, also bound IL-4 very tightly, however this method was unable to determine the binding affinity due to positive dissociation effects and the sensitivity level of the BIACore™ technique (*). Note that the anti-IL-4 dAb alone (DOM9-1 12-210) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL4 mAb (Pascolizumab) was used as a positive control to demonstrate IL-4 binding in this assay.

18.8 BIACore analysis of effect of IL-4 binding to mAbdAbs on subsequent IL-13 binding kinetics and vice versa; and the effect of IL-13 binding to mAbdAbs on subsequent IL-4 binding kinetics and vice versa.

The IL-13 and IL-4 BIACore™ binding assays were also used to investigate the effect of IL-4 binding to PascoH-474 GS removed on subsequent IL-13 binding kinetics and vice versa; and the effect of IL-13 binding to 586H-TVAAPS-210 on subsequent IL-4 binding kinetics and vice versa. Analyses were carried out on the BIACore™ T100 machine at 25°C, using anti-human IgG capture of the mAbdAb (or positive control mAb). Briefly, anti-human IgG was coupled onto a CM5 chip by primary amine coupling in accordance with the manufactures recommendations. mAbdAb constructs (or positive control mAb) were then captured onto this surface (at approximately 250 to 750RUs) and the first analyte (either human IL-13 or human IL-4) was passed over at 256nM for 4 minutes. The second analyte (human IL-4 or human IL-13 respectively) was then passed over at concentrations of 256nM, 64nM, 16nM, 4nM,
1nM and 0.25nM, and for double referencing a buffer injection was passed over the capture antibody or mAbdAb surface. The data was analysed (fitted to the 1:1 model of binding) using the evaluation software in the machine. The surface was then regenerated using 3M magnesium chloride. The data from these experiments are shown in Tables 27 and 28.

</tbody>
</table>

The binding affinity of PascoH-474 GS removed for human IL-13 was similar, irrespective of whether human IL-4 was bound to this molecule or not. In addition, the binding affinity of 586H-TVAAPS-210 for human IL-13 was similar, irrespective of whether human IL-4 was bound to this molecule or not and it was also similar to the binding affinity of the anti-IL13 mAb for human IL-13.

The off-rates (kd) for IL-4 binding obtained for PascoH-474 GS removed and 586H-TVAAPS-210, are very slow and out of the sensitivity range of the BIAcore™ T100 hence could not be used as an accurate determination of the binding affinity (data not shown). However, the data do indicate that all of the constructs tested bind very tightly to human IL-4. Thus the binding affinity of PascoH-474 GS removed for human IL-4 was very tight, irrespective of whether human IL-13 was bound to this molecule or not. In addition, the binding affinity of 586H-TVAAPS-210 for human IL-4 was very tight, irrespective of whether human IL-13 was bound to this molecule or not.

18.9 Potency of mAbdAbs
mAbdAbs were tested for inhibition of human IL-4 binding to human IL-4Rα by ELISA, as described in Method 19. All of the molecules shown in Table 28 were tested in one experiment, however the data have been plotted on two graphs to distinguish between the curve plots (586H-TVAAPS-210 was run twice, this is labelled as sample 1 and sample 2 in table 25). These data are shown in Figures 102 and 103.
PascoH-474 GS removed, inhibited binding of human IL-4 to human IL4Rα similarly to Pascolizumab. 586H-210 GS removed, 586H-TVAAPS-210 GS removed, 586H-TVAAPS-210, 586H-210, 586H-G4S-210 and 586H-ASTKG-210 all inhibited binding of human IL-4 to human IL4Rα similarly to D0M9-1 12-210. Pascolizumab and D0M9-112-210 were included as positive controls for the inhibition of IL-4 binding to IL4Rα. DOM10-53-474 and an isotype-matched mAb (with specificity for an irrelevant antigen) were included as negative controls for the inhibition of IL-4 binding to IL4Rα.

These data were also used to determine IC₅₀ values for each molecule. The IC₅₀ value is the concentration of mAb or mAb or dAb, which is able to inhibit binding of human IL-4 to human IL4Rα by 50%. The IC₅₀ values are shown in Table 28.

</table>

These data confirm that PascoH-474 GS removed behaves similarly to Pascolizumab and that all 586H-210 mAbdAb 'family members' behave similarly to the DOM9-1 12-210 dAb.

18.10 Neutralisation of human and cynomolgus IL-13 in TF-1 cell bioassays by mAbdAbs

A number of purified mAbdAbs were tested for neutralisation of human and cynomolgus IL-13 in TF-1 cell bioassays (as described in method 8 and method 20 respectively). Each molecule was tested between one and nine times in these assays, not all graphs are shown, but Figures 104 and 105 are representative graphs showing the neutralisation data for human IL-13 and cynomolgus IL-13 respectively. DOM10-53-474 was included as a positive control for neutralisation of human or cynomolgus IL-13 in the bioassays. A dAb with specificity for an irrelevant antigen (negative control dAb) was also included as a negative control for neutralisation of human or cynomolgus IL-13 in the bioassays.
PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed and PascoH-ASTKG-474 2nd GS removed, as well as PascoH-616, PascoH-TVAAPS-616 and DOM10-53-616 (these are described in Example 19), fully neutralised the bioactivity of both human and cynomolgus IL-13 in TF-1 cell bioassays.

18.1.1 Neutralisation of human and cynomolgus IL-4 in TF-1 cell bioassays by mAbdAbs

A number of purified mAbdAbs were also tested for neutralisation of human and cynomolgus IL-4 in TF-1 cell bioassays (as described in method 9 and method 21 respectively). Each molecule was tested twice in these assays, not all graphs are shown, but Figures 106 and 107 are representative graphs (from the dataset) showing neutralisation data for human IL-4 and cynomolgus IL-4 respectively. The anti-IL13 mAb was included as a negative control and Pascolizumab was included as a positive control for neutralisation of human or cynomolgus IL-4 in the bioassays. In addition, PascoH-474, PascoH-TVAAPS-474, PascoH-ASTKG-474 and PascoH-G4S-474 were also tested for neutralisation of human and cynomolgus IL-4 in these bioassays.

PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed, fully neutralised the bioactivity of both human and cynomolgus IL-4 in TF-1 cell bioassays. In addition PascoH-474, PascoH-TVAAPS-474, PascoH-ASTKG-474 and PascoH-G4S-474 also fully neutralised the bioactivity of human IL-4 in the TF-1 cell bioassay.

ND$_{50}$ values were derived based on data obtained from a number of different experiments. The ND$_{50}$ value is the concentration of mAbdAb or mAb or dAb, which is able to neutralise the bioactivity of IL-13 or IL-4 by 50%. The mean ND$_{50}$ value, the standard deviation (SD) and the number of times tested (n) are shown in table 29.

### Table 29

</tbody>
</table>
PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed, and PascoH-ASTKGPT-474 2nd GS removed, all fully neutralised the bioactivity of human and cynomolgus IL-13 in TF-1 cell bioassays. In addition, the neutralisation potencies (ND$_{50}$ values) of PascoH-474 GS removed, PascoH-TVAAPS-474 GS removed, and PascoH-ASTKGPT-474 2nd GS removed, for human IL-13 were similar and withinfold of the ND$_{50}$ value for purified anti-IL13 dAb alone (DOM10-53-474).

PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed, both fully neutralised the bioactivity of human and cynomolgus IL-4 in TF-1 cell bioassays. In addition, the neutralisation potencies (ND$_{50}$ values) of PascoH-474 GS removed and PascoH-TVAAPS-474 GS removed, for human IL-13 and cyno IL-13 were similar and withinfold of the ND$_{50}$ value for Pascolizumab.

18.12 Ability of mAbdAbs to inhibit binding of human IL-13 binding to human IL13Rα2

The molecules listed in Table 30 were tested for inhibition of human IL-13 binding to human IL13Rα2 by ELISA, as described in Method 22. All molecules were tested in one experiment. The data are shown in Figure 108.

All mAbdAbs tested inhibited binding of human IL-13 to human IL13Rα2. The level of inhibition was similar to that of DOM10-53-474, DOM10-53-616 and the anti-IL13 mAb. Pascolizumab and a negative control dAb (with specificity for an irrelevant antigen), were included as negative controls for the inhibition of IL-13 binding to IL13Rα2.

These data were also used to determine IC$_{50}$ values for each molecule. The IC$_{50}$ value is the concentration of mAbdAb or mAb or dAb, which is able to inhibit binding of human IL-13 to human IL13Rα2 by 50%. The IC$_{50}$ values are shown in Table 30.

19.2 Expression and purification of mAbdAbs containing the anti-IL13 DOM10-53-616 dAb
These mAbdAbs were expressed in HEK293-6E cells and CHOE1a cells as described in example 1.3.

The mAbdAbs were purified and analysed by SEC and SDS PAGE. A number of purified preparations of PascoH-616 and PascoH-TVAAPS-616 mAbdAbs were made, the SEC and SDS PAGE data shown in Figures 109 (SEC profile for PascoH-616), 110 (SEC profile for PascoH-TVAAPS-616), 111(SDS PAGE for PascoH-616) and 112 (SDS PAGE for PascoH-TVAAPS-616), are representative of these preparations.

19.3 Binding of mAbdAbs to human IL-13 in a direct binding ELISA
PascoH-616 and PascoH-TVAAPS-616 purified mAb dAbs were tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 113.
Purified PascoH-616 and PascoH-TVAAPS-616 both bound human IL-13. Purified anti-human IL4 mAb alone (Pascolizumab) was included in this assay as a negative control for binding to IL-13. Purified anti-human IL13 mAb was included as a positive control for IL-13 binding. Note that the anti-IL-13 dAb alone (DOM1 0-53-61 6) was not tested in this assay as the dAb is not detected by the secondary detection antibody; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

19.4 Biacore analysis for binding to human IL-4 and human IL-13
Purified mAbdAbs were tested for binding to human IL-4 and human IL-13 using the BIAcore™ T100 at 25°C (as described in methods 4 and 5). These data are shown in Table 32.
In experiment 1, a mAbdAb capture level of approximately 600 relative response units was achieved and six IL-13 and IL-4 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed. Only one IL-13 (256nM) and IL-4 (256nM) concentration curve was assessed for the mAbs in experiment 1.
In experiment 2, a mAbdAb a capture level of approximately 400 relative response units was achieved and six IL-4 (64nM, 16nM, 4nM, 1nM, 0.25nM and 0.0625nM) and six IL-13 concentration curves (256nM, 64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed. In experiment 2, only one IL-13 concentration curve (256nM) was assessed for the anti-IL13 mAb and five IL-4 concentration curves (64nM, 16nM, 4nM, 1nM and 0.25nM) were assessed for Pascolizumab.

PascoH-616 and PascoH-TVAAPS-616 both bound IL-4 with similar binding affinities and this was similar to the binding affinity of the anti-human IL4 mAb alone (Pascolizumab). PascoH-616 and PascoH-TVAAPS-616 both bound IL-13. Note that the anti-IL-13 dAb alone (DOM1 0-53-61 6) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.
19.5 Biacore analysis for binding to cynomolgus IL-13

Purified mAbdAbs were also tested for binding to cynomolgus IL-13 using the BIAcore™ T100 at 25°C (as described in method and 30). These data are shown in Table 33. A mAbdAb capture level of approximately 400 relative response units was achieved and six IL-13 concentration curves (256, 64, 16, 4, 1 and 0.25nM) were assessed. There was only one IL-13 concentration curve (256nM) for the anti-IL13 mAb.

PascoH-616 and PascoH-TVAAPS-616 both bound cynomolgus IL-13 with similar binding affinities. Note that the anti-IL-13 dAb alone (DOM10-53-616) was not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

19.6 Neutralisation of human and cynomolgus IL-13 in TF-1 cell bioassays by mAbdAbs

Purified mAbdAbs were tested for neutralisation of human IL-13 and cynomolgus IL-13 in TF-1 cell bioassays (as described in method 8 and method 20 respectively). These molecules were tested 3 times in each assay, and Figure 114 is a representative graph showing the neutralisation data for human IL-13. Figure 114a is a representative graph showing the neutralisation data for cyno IL-13. DOM10-53-616 was included as a positive control for neutralisation of IL-13 in this bioassay. A dAb with specificity for an irrelevant antigen (negative control dAb) was also included as a negative control for neutralisation of IL-13 in this bioassay.

The mean ND₅₀ value, the standard deviation (SD) and the number of times tested (n) are shown in table 34.

Table 34

<table>

</table>

140
Both PascoH-616 and PascoH-TVAAPS-616, as well as in addition mAbdAbs PascoH-TVAAPS-474 GS removed and PascoH-474 GS removed fully neutralised the bioactivity of human and cynomolgus IL-13 in TF-1 cell bioassays.

In addition, the neutralisation potencies (ND\textsubscript{50} values) of PascoH-616 and PascoH-TVAAPS-616 for human IL-13 were similar and within 2-fold of the ND\textsubscript{50} value for the purified anti-IL13 dAb alone (DOM10-53-616).

PascoH-616 and PascoH-TVAAPS-616 were also tested for inhibition of human IL-13 binding to human IL-13R\alpha2 by ELISA, as described in Method 22. These data are presented in Example 18.12.

**Example 20**

**Ability of mAbdAbs to neutralise human IL-13 or IL-4 in a human whole blood phospho STAT6 bioassay**

The ability of mAbdAbs to neutralise human IL-13 or IL-4 in a human whole blood phospho STAT6 bioassay was carried out as described in Method 16. The IL-4 or IL-13 neutralisation potencies (ie. inhibition of IL-4 or IL-13 bioactivity) of 2 mAbdAb constructs (the purified anti-IL13mAb-anti-IL4dAb, 586H-TVAAPS-210; and the purified anti-IL4mAb-anti-IL13dAb, PascoH-474 GS removed) were determined. Purified anti-human IL-4 mAb (Pascalizumab) and purified anti-IL4 dAb (DOM9-1 12-210) were included as positive controls for neutralisation of rhlL-4 in this assay. Purified anti-human IL-13 mAb and purified anti-IL13 dAb (DOM1 0-53-474) were included as positive controls for neutralisation of rhlL-13. An isotype matched mAb mixed with a dAb (both with specificities for irrelevant antigens), were included as a negative control for neutralisation of rhlL-4 or rhlL-13. Each molecule was tested at least twice, using blood from different donors. Figures 115 to 124 are graphs showing representative data.

The purified mAbdAbs fully neutralised the bioactivity of rhlL-13 and rhlL-4.
As described in method 16, the ability of the test molecules to neutralise rhIL-13 or rhIL-4 bioactivity was expressed as the concentration of the molecules (e.g. mAbdAbs) required to neutralise 2ng/ml of human IL-4 or human IL-13 by 50% (IC$_{50}$). These data are shown in Table 35. The combined mean IC$_{50}$ from all donors for each molecule is presented, along with the standard deviation.

Comparison of IC$_{50}$ values indicated that 586-TVAAPS-210 inhibited IL-13 and IL-4 induced pSTAT-6 similarly to the anti-IL13 mAb and DOM9-112-210 (in the IL-13 and IL-4 whole blood assays respectively). Comparison of IC$_{50}$ data also indicated that PascoH-474 GS removed, inhibited IL-13 and IL-4 induced pSTAT-6 similarly to DOM10-53-474 and Pascolizumab (in the IL-13 and IL-4 whole blood assays respectively). The control mAb showed no inhibition up to the maximum concentration tested of 661 nM in all donors, and the control dAb showed no neutralisation up to the maximum concentration tested of 2291 nM in all donors.

**Example 21**
**Rat PK studies of the Dual Targeting anti-IL4/anti-IL13 mAbdAb**

PascoH-G4S-474, PascoL-G4S-474, 586H-TVAAPS-21 0 and 586H-TVAAPS-1 54 were assessed in rat PK studies (as summarised in Table 35.1). In brief, male Sprague-Dawley rats (approximately 200 grams to 220 grams in weight) were given a single intravenous (i/v) administration of mAbdAb at a target dose level of 2mg/kg. At allotted time points (0 hours through to 312 hours) 100µl blood samples were withdrawn and processed for plasma. The rat plasma samples were evaluated for the presence of the test molecule in a human IgG detection assay, and/or an IL-13 ligand binding assay, and/or an IL-4 ligand binding assay. In addition, the PK profile in plasma for Pascolizumab (in rat) was also evaluated: in this case the rat plasma samples were evaluated for the presence of Pascolizumab in a human IgG detection assay and an IL-4 ligand binding assay.
In a first study, pascolizumab was given to 4 rats. In a second study, there were four treatment groups (2mg/kg PascoH-G4S-474, 2mg/kg PascoL-G4S-474, 2mg/kg 586H-TVAAPS-210 and 2mg/kg 586H-TVAAPS-154), with 4 rats in each group.

The PK parameters (shown in Table 35.1) were derived from plasma concentration-time profile data (which are not shown). Note that, some plasma samples were analysed more than once in these assays and the PK parameters in Table 35.1 were derived from only one of these datasets. Also note that the PK parameters have not been normalised for individual animal doses, instead nominal doses of 2mg/kg have been assumed. Note that some technical difficulties were encountered with the IgG PK assay for PascoH-G4S-474 hence the concentrations may be overestimated. In addition, analysis of the IgG plasma concentration-time profiles was performed twice in some cases (at analysis 1 and analysis 2, as annotated in Table 35.1). Analysis of the plasma concentration-time profile data generated from the IL-13 and IL-4 ligand binding PK assays was only performed at analysis 2. The plasma concentration-time profile data generated from the IL-13 and IL-4 ligand binding assays for PascoL-G4S-474 and 586H-TVAAPS-154 have not been used to derive PK parameters for these molecules.

</tbody>
</table>

Plasma concentration-time profile data, generated in the IL-13 and IL-4 assays for PascoH-G4S-474 (and subsequent derived PK parameters), tended to be comparable; this was also the case for the plasma concentration-time profile data
generated in the IL-13, IL-4 and IgG PK assays for 586H-TVAAPS-210 (and subsequent derived PK parameters). This suggests that these mAbdAbs were 'intact' in the rat plasma throughout the course of the study. The derived PK parameters for 586H-TVAAPS-154 appeared to be more similar to the derived PK parameters for Pascolizumab than any of the other mAbdAbs.

**Example 22**  
**Cyno PK studies**

PK studies were carried out in cynomolgus monkeys. The animals were given a single intravenous administration at a target dose level of 1mg/kg. At allotted time points, 500μl blood samples were withdrawn and processed for plasma. The cynomolgus plasma samples were then evaluated for the presence of the test molecule in an IL-13 ligand binding assay, an IL-4 ligand binding assay and an IL-13/IL-4 bridging assay.

Preliminary data from these studies with the mAbdAbs 'PascoH-474 GS removed' and '586H-TVAAPS-210' are consistent with the rat PK data shown above and indicated that these molecules are cleared from the systemic circulation more rapidly than a mAb but less rapidly than a dAb.

**Example 23**

**23.1 Generation of a Dual targeting anti-EGFR/anti-VEGF mAbdAb**

This dual targeting mAbdAb was constructed by fusion of a dAb to the C-terminus of the mAb heavy chain. The anti-EGFR mAb heavy and light chain expression cassettes had been previously constructed. The restriction sites which were used for cloning are the same as those set out in Example 10 (Sail and Hindi 1).

DNA coding an anti-VEGF dAb (DOM1 5-26-593) was then amplified by PCR (using primers coding Sail and Hindi 11 ends) and inserted into the modified 3’ coding region, resulting in a linker of 'STG' (serine, threonine, glycine) between the mAb and the dAb.

Sequence verified clones (SEQ ID NO: 164 and 243) for light and heavy chains respectively were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the manufacturer's protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 165 and 137).

**23.2 Purification and SEC analysis of the Dual targeting anti-EGFR/anti-VEGF mAbdAb**

This dual targeting mAbdAb was purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations
of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis (Figure 128) of the purified sample (designated DMS4010) shows non-reduced sample running at -170kDa whilst reduced sample shows two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-VEGF mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 1ml/min. The SEC profile shows a single species running as a symmetrical peak (figure 129).

### 23.3 Potency of the Dual targeting anti-EGFR/anti-VEGF mAbdAb
The ability of the molecule to neutralise VEGF and EGFR were determined as described in methods 12 and 13 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 130) of this mAbdAb (designated DMS4010) was calculated to be 4.784nM whilst the control, an anti-EGFR mAb gave an EC50 value of 4.214nM. In the anti-VEGF receptor binding assay (Figure 131) the EC50 of the mAbdAb (designated DMS4010) was 58pM (0.058nM) whilst an anti-VEGF control mAb produced an EC50 of 214.1 pM (0.2141 nM). In conclusion, assay data shows that the construct of example 23, a dual targeting anti-EGFR/anti-VEGF mAbdAb is potent against both antigens.

### 23.4 PK of the dual targeting anti-EGFR/anti-VEGF mAbdAb
The pharmacokinetic profile of the dual targeting anti-EGFR/anti-VEGF mAbdAb (designated DMS4010) was determined after administration to cynomolgus monkeys. The compound was administered at a dose of 5mg/kg i.v. and the serum levels of drug at multiple time points post-administration was determined by binding to both EGFR and VEGF in separate ELISA assays. Figure 132 shows the results for this assay in which the data was compared with historical data that had been generated for the mAbs cetuximab (anti-EGFR) and bevacizumab (anti-VEGF). Further details are shown in table 36.

### 23.5 Generation of an alternative anti-EGFR/anti-VEGF mAbdAb
An alternative anti-EGFR/anti-VEGF mAbdAb was constructed in a similar way to that described above in Example 11.1, using the same anti-EGFR mAb linked to a VEGF dAb on the C-terminus of the heavy chain using an STG linker. The anti-VEGF dAb used in this case was DOM15-10-11. This molecule was expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 165 and 186), however significantly reduced levels of expression were achieved in comparison to the expression of the molecule described in Example 23.2. When tested for potency in the same VEGF assay as described in Example 23.3 it was found to have undetectable levels of inhibition of VEGF binding to VEGF receptor in this assay.

Example 24

24.1 Generation of a dual targeting anti-EGFR/anti-VEGF mAbdAb with no linker
A derivative of the mAbdAb described above in Example 23 was made where the ‘STG’ linker between the dAb and the CH3 domain of the mAb was removed. SDM was used to delete the residues encoding the STG linker from the plasmid encoding the heavy chain. Sequence verified clones for light and heavy chains (SEQ ID NO: 243 and SEQ ID NO: 174) respectively were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the manufacturer’s protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 175 and 137).

24.2 Purification and SEC analysis of the dual targeting anti-EGFR/anti-VEGF mAbdAb with no linker
This dual targeting mAbdAb was purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis (Figure 133) of the purified sample (designated DMS401 1) shows non-reduced sample running at ~170kDa whilst reduced sample shows two bands running at ~25 and ~60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-VEGF mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 1ml/min. The SEC profile shows a single species running as a symmetrical peak (figure 134).

24.3 Potency of the dual targeting anti-EGFR/anti-VEGF mAbdAb with no linker
The ability of the molecule to neutralise VEGF and EGFR were determined as described in methods 12 and 13 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response
curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 135) of this mAbdAb (designated DMS401 1) was calculated to be 3.529nM whilst the control, an anti-EGFR mAb gave an EC50 value of 3.647nM. In the anti-VEGF receptor binding assay (Figure 136) the EC50 of the mAbdAb (designated DMS401 1) was 342.9pM (0.3429nM) whilst an anti-VEGF control mAb produced an EC50 of 214.1 pM (0.2141 nM). In conclusion, assay data shows that the construct of example 24, a dual targeting anti-EGFR/anti-VEGF mAbdAb with no linker is potent against both antigens.

Example 25

Generation of a dual targeting anti-EGFR/anti-VEGF mAbdAb with longer linkers

Derivatives of the mAbdAb described above in Example 23 were made where the linker between the dAb and the CH3 domain of the mAb was lengthened by the insertion of one or two repeats of a flexible "GGGS" motif into the plasmid encoding the heavy chain.

The first molecule with a heavy chain sequence as set out in SEQ ID NO: 175 has one repeat of this motif, hence having a linker of 'STGGGGG'.

The second molecule with a heavy chain sequence as set out in SEQ ID NO: 177 has two repeats of this motif, hence having a linker of 'STGGGGSGGG'.

These were both independently paired with the same light chain as used in Example 23 (SEQ ID NO: 243)

Sequence verified clones for light and heavy chains were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the manufacturer's protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 176 and 137 which is designated DMS4023; and SEQ ID NO: 178 and 137 which is designated DMS4024).

Purification and SEC analysis of the dual targeting anti-EGFR/anti-VEGF mAbdAb with longer linkers

These dual targeting mAbdAbs were purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols.

Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis of the purified samples DMS4023 and DMS4024 (Figure 137) shows non-reduced samples running at ~170kDa whilst reduced samples show two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-VEGF mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 1ml/min. The SEC profile for both DMS4023
(Figure 138) and DMS4024 (Figure 139) show a single species with a slightly trailing peak.

25.3 Potency of the dual targeting anti-EGFR/anti-VEGF mAbdAb with longer linkers

The ability of the molecule to neutralise VEGF and EGFR were determined as described in methods 12 and 13 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 140) of the mAbdAb DMS4023 was calculated to be 7.066nM and the potency of mAbdAb DMS4024 was calculated to be 6.42OnM whilst the control, an anti-EGFR mAb gave an EC50 value of 7.291 nM. In the anti-VEGF receptor binding assay (Figure 141) the EC50 of the mAbdAb DMS4023 was 91.79pM (0.091 nM) and the EC50 of the mAbdAb DMS4024 was 90pM (0.0906nM) whilst an anti-VEGF control mAb produced an EC50 of 463.2pM (0.4632nM). In conclusion, assay data shows that the constructs of example 25, dual targeting anti-EGFR/anti-VEGF mAbdAbs with longer linkers are potent against both antigens.

Example 26

26.1 Generation of a dual targeting anti-VEGF/anti-EGFR mAbdAb

This dual targeting mAbdAb was constructed by fusion of a dAb to the C-terminus of the mAb heavy chain. The anti-VEGF mAb heavy and light chain expression cassettes had been previously constructed. The restriction sites which were used for cloning are the same as those set out in Example 10 (Sail and Hindi 11).

DNA coding an anti-EGFR dAb (DOM1 6-39-542) was then amplified by PCR (using primers coding Sail and HindIII ends) and inserted into the modified 3' coding region, resulting in a linker of 'STG' (serine, threonine, glycine) between the mAb and the dAb.

Sequence verified clones (SEQ ID NO: 179 and 181) for light and heavy chains respectively) were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the manufacturer's protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 180 and 182).

26.2 Purification and SEC analysis of the dual targeting anti-VEGF/anti-EGFR mAbdAb

These dual targeting mAbdAbs were purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis of the purified sample (designated DMS4009) (Figure 142) shows non-reduced samples running at
-170kDa whilst reduced samples show two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-VEGF mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 1ml/min. The SEC profile for this molecule (Figure 143) shows a single species with a symmetrical peak.

26.3 Potency of the dual targeting anti-VEGF/anti-EGFR mAbdAb

The ability of the molecule to neutralise VEGF and EGFR were determined as described in methods 12 and 13 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 144) of the mAbdAb DMS4009 was calculated to be 132.4nM whilst the control, an anti-EGFR mAb gave an EC50 value of 6.585nM. In the anti-VEGF receptor binding assay (Figure 145) the EC50 of the mAbdAb was 539.7pM (0.5397nM) whilst an anti-VEGF control mAb produced an EC50 of 380.5pM (0.3805nM). In conclusion, assay data shows that the construct of example 26, a dual targeting anti-VEGF/anti-EGFR mAbdAb is potent against both antigens.

Example 27

27.1 Generation of a dual targeting anti-EGFR/anti-IL-13 mAbdAb

This dual targeting mAbdAb was constructed by fusion of a dAb to the C-terminus of the mAb heavy chain. The anti-EGFR mAb heavy and light chain expression cassettes had been previously constructed. The restriction sites which were used for cloning are the same as those set out in Example 10 (Sail and Hindi 1).

DNA coding an anti-IL-13 dAb (DOM1 0-53-474) was then amplified by PCR (using primers coding Sail and Hindi 1 ends) and inserted into the modified 3' coding region, resulting in a linker of 'STG' (serine, threonine, glycine) between the mAb and the dAb. Sequence verified clones (SEQ ID NO: 243 and 183) for light and heavy chains respectively) were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the manufacturer's protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 137 and 184).

27.2 Purification and SEC analysis of the dual targeting anti-EGFR/anti-IL-13 mAbdAb

These dual targeting mAbdAbs were purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from
measurements of light absorbance at 280nm. SDS-PAGE analysis of the purified sample (designated DMS4029) (Figure 146) shows non-reduced samples running at -170kDa whilst reduced samples show two bands running at -25 and -60kDa corresponding light chain and dAb-fused heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-IL-13 mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 0.5ml/min. The SEC profile for this molecule (Figure 147) shows a single species with a symmetrical peak.

27.3 Potency of the dual targeting anti-EGFR/anti-IL-13 mAbdAb

The ability of the molecule to neutralise EGFR and IL-13 were determined as described in methods 13 and 25 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 148) of the mAbdAb DMS4029 was calculated to be 9.033nM whilst the control, an anti-EGFR mAb gave an EC50 value of 8.874nM. In the IL-13 cell-based neutralisation assay (Figure 149) the EC50 of the mAbdAb was 1.654nM whilst an anti-IL-13 control dAb produced an EC50 of 0.996nM. In conclusion, assay data shows that the construct of example 27, a dual targeting anti-EGFR/anti-IL-13 mAbdAb is potent against both antigens.

Example 28

28.1 Generation of a dual targeting anti-EGFR/anti-VEGF mAbdAbs where the dAb is located on the light chain

Dual targeting anti-EGFR/anti-VEGF mAbdAbs were constructed by fusion of a dAb to the C-terminus of the mAb light chain. The anti-EGFR mAb heavy and light chain expression cassettes had been previously constructed.

To introduce restriction sites for dAb insertion in the light chain, site directed mutagenesis was used to create BamHI and HindIII cloning sites using the mAb light chain expression vector as a template. DNA coding an anti-VEGF dAb (DOM15-26-593) was then amplified by PCR (using primers coding BamHI and HindIII ends) and inserted into the modified 3’ coding region, resulting in a linker of either 'GSTG' or 'GSTVAAPS' between the mAb and the dAb.

The first molecule with a light chain sequence as set out in SEQ ID NO: 187 has a linker of 'GSTG'.
The second molecule with a light chain sequence as set out in SEQ ID NO: 189 has a linker of 'GSTVAAPS'.

These were both independently paired with the heavy chain of SEQ ID NO: 245.

Sequence verified clones for light and heavy chains were selected and large scale DNA preparations were made using Qiagen Mega Prep Kit following the
manufacturer’s protocols. mAbdAbs were expressed in mammalian HEK293-6E cells using transient transfection techniques by co-transfection of light and heavy chains (SEQ ID NO: 188 and 139 which is designated DMS4013; and SEQ ID NO: 190 and 139 which is designated DMS4027).

28.2 Purification and SEC analysis of the dual targeting anti-EGFR/anti-VEGF mAbdAbs where the dAb is located on the light chain

These dual targeting mAbdAbs were purified from clarified expression supernatant using Protein-A affinity chromatography according to established protocols. Concentrations of purified samples were determined by spectrophotometry from measurements of light absorbance at 280nm. SDS-PAGE analysis of the purified samples DMS4013 and DMS4027 (Figure 150) shows non-reduced samples running at ~170kDa whilst reduced samples show two bands running at ~38 and ~50kDa corresponding to dAb-fused light chain and heavy chain respectively.

For size exclusion chromatography (SEC) analysis the anti-EGFR/anti-VEGF mAbdAb was applied onto a S-200 10/300 GL column (attached to an HPLC system) pre-equilibrated and running in PBS at 1ml/min. The SEC profile for both DMS4013 (Figure 151) and DMS4027 (Figure 152) show a single species with a symmetrical peak.

28.3 Potency of the dual targeting anti-EGFR/anti-VEGF mAbdAbs where the dAb is located on the light chain

The ability of the molecule to neutralise VEGF and EGFR were determined as described in methods 12 and 13 respectively. Assay data were analysed using GraphPad Prism. Potency values were determined using a sigmoidal dose response curve and the data fitted using the best fit model. Anti-EGFR potency (Figure 153) of the mAbdAb DMS4013 was calculated to be 7.384nM and the potency of mAbdAb DMS4027 was calculated to be 7.554nM whilst the control, an anti-EGFR mAb gave an EC50 value of 7.093nM. In the anti-VEGF receptor binding assay (Figure 154) the EC50 of the mAbdAb DMS4013 was 1.179nM and the EC50 of the mAbdAb DMS4027 was 0.1731 nM whilst an anti-VEGF control mAb produced an EC50 of 0.130nM. In conclusion, assay data shows that the constructs of example 28, dual targeting anti-EGFR/anti-VEGF mAbdAbs where the dAb is located on the light chain are potent against both antigens.

Example 29

Biacore analysis of dual targeting anti-EGFR/anti-VEGF and anti-TNF/anti-VEGF mAbdAbs

The mAbdAbs described in example 11 (anti-TNF/anti-VEGF mAbdAb) and examples 23, 24, 25 and 28 (anti-EGFR/anti-VEGF mAbdAbs) were subjected to BIAcore analysis to determine kinetic association and dissociation constants for
binding to their corresponding antigens. Analysis was performed on BIAcore™ 3000 instrument. The temperature of the instrument was set to 25°C. HBS-EP buffer was used as running buffer. Experimental data were collected at the highest possible rate for the instrument. One flow cell on a research grade CM5 chip was coated with protein A using standard amine coupling chemistry according to manufacturers instructions, and a second flow cells was treated equally but buffer was used instead of protein A to generate a reference surface. The flow cell coated with protein A was then used to capture mAbdAbs. Antigen was injected as a series 2x serial dilutions as detailed in table 37. Several dilutions were run in duplicate. Injections of buffer alone instead of ligand were used for background subtraction. Samples were injected in random order using the kinetics Wizard inherent to the instrument software. The surface was regenerated at the end of each cycle by injecting 10mM Glycine, pH 1.5. Both data processing and kinetic fitting were performed using BIAevaluation software 4.1. Data showing averages of duplicate results (from the same run) is shown in Table 37. The multiple values shown for DMS4010 represent two experiments run on separate occasions. The value of 787nM probably overestimates the affinity due to the concentrations of ligand analysed.

**Example 30**

Trispecific antibodies which comprise single domain antibodies fused onto a bispecific antibody scaffold

30.1 Construction
Genes encoding variable heavy and light domains of a bispecific antibody molecule which has specificity for IL-18 and IL-12 antigens (for further information see WO 2007/024715) were constructed de-novo with appropriate restriction enzyme sites and signal sequence added. Using standard molecular biology techniques, the variable heavy domains were cloned into an expression vector containing the IgGl heavy chain constant region fused to an anti-IL4 domain antibody DOM9-12-210 (SEQ ID NO: 4) via a TVAAPS linker at the c-terminus of the constant region. The light chain variable domain was similarly cloned into an expression vector containing the Ck constant region sequence. The antibodies constructed and expressed are listed in Table 38.

</tbody>
</table>

30.2 Expression and purification
Briefly, 25 ml of HEK293 cells at 1.5x10^6 cells/ml were co-transfected with heavy and light chain expression plasmids previously incubated with 293fectin reagent (Invitrogen # 51-0031). These were placed in a shaking incubator at 37°C, 5% CO₂, and 95%RH. After 24 hours Tryptone feeding media was added and the cells grown for a further 48 hours. Supernatant was harvested by centrifugation and IgG levels quantified by ELISA. The resulting mAbdAb was designated BPC1616 (SEQ ID NO: 193 and 194)

30.3 IL-12 binding ELISA
The cell supernatant from the transfections were assessed for binding to recombinant human IL-12. Briefly, ELISA plates coated with anti-human IL-12 (R&D Systems AF219NA) at 2μg/ml and blocked with blocking solution (4% BSA in Tris buffered saline). The plates were then loaded with 25ng/ml recombinant human IL-12 (PeproTech #200-12) in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Various dilutions of the cell supernatant were added as well as irrelevant control antibodies (Pascolizumab and an isotyped matched control hlgG) diluted in blocking solution. The plate was incubated for 1 hour at room temperature before washing in TBST. Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.
The results are presented in Figure 155 and show that BPC1616 binds to recombinant human IL-12 whereas the two control antibodies showed no binding.

30.4 IL-18 binding ELISA

The cell supernatants from the transfections were assessed for binding to recombinant human IL-18. Briefly, ELISA plates were coated with human IL-18 (made at GSK) at 1µg/ml and blocked with blocking solution (4% BSA in Tris buffered saline). Various dilutions of the cell supernatant were added as well as irrelevant antibodies (Pascolizumab and an isotype matched control human IgG), diluted in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted. The results are presented in Figure 156 and show that BPC1616 binds to recombinant human IL-18 whereas the two control antibodies show no binding.

30.5 IL-4 Binding ELISA

The cell supernatants from the transfections were assessed for binding to recombinant human IL-4. Briefly, ELISA plates were coated with human IL-4 (made at GSK) at 1µg/ml and blocked with blocking solution (4% BSA in Tris buffered saline). Various dilutions of the cell supernatant were added as well as an anti IL-4 monoclonal antibody (Pascolizumab) and irrelevant antibody (Isotype matched control hlgG.), diluted in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.

The results are presented in Figure 157 show that BPC1616 and Pascolizumab bind to recombinant human IL-4 whereas the control antibody shows no binding.

**Example 31**
Trispecific mAbdAbs comprising two single domains antibodies fused in-line at the C-terminus of a monoclonal antibody

31.1 Construction

Three trispecific antibodies (mAbdAb-dAb) were constructed where two single
domain antibodies are fused in-line at the C-terminus of the heavy chain of a monoclonal antibody.

Briefly, a BgIII restriction site at the N-terminus and BamHI restriction site at the C-terminus were introduced by PCR to flank the DNA sequences encoding the domain antibodies into the DOM10-53-474 (SEQ ID NO: 5), DOM9-155-154 (SEQ ID NO: 3) and DOM9-1 12-210 (SEQ ID NO: 4).

The DNA fragment encoding the DOM10-53-474 domain antibody was then cloned into a BamHI site of mammalian expression vector encoding the heavy chain of an anti IL-5 monoclonal antibody fused with an anti IL-4 domain antibody DOM9-1 12-210 (SEQ ID NO: 71). The DNA fragments encoding the DOM9-155-154 and DOM9-112-210 domain antibodies were both independently cloned into the BamHI site of a mammalian expression vector encoding the heavy chain of an anti-CD20 monoclonal antibody fused with an anti IL-13 domain antibody DOM10-53-474 (SEQ ID NO: 116). The resulting expression vectors encode a heavy chain with two single domain antibodies fused onto the C-terminus. The protein sequences of the heavy chains are given in SEQ ID NO: 195, 196 and 197 as set out in Table 39.

Table 39 is a summary of the mAbdAbs that have been constructed.

3.1.2 Expression and purification

Expression plasmids encoding the heavy and light chains of BPC1008, BPC1009 and BPC1010 were co-transfected into HEK 2936E cells using 293fectin (Invitrogen, 12347019). A tryptone feed was added to the cell culture the following day and the supernatant material was harvested after about 2 to 6 days from initial transfection.
The antibodies were purified using a Protein A column before being tested in binding assays.

3.1.3: IL-4 Binding ELISA

96-well high binding plates were coated with 5µg/ml human IL-4 (GSK) in Coating buffer (0.05M bicarbonate pH9.6, Sigma C-3041) and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20 (TBST). 100µL of blocking solution (1% BSA in TBST buffer) was added in each well and the plates were incubated for at least one hour at room temperature. The purified antibodies were successively diluted across the plates in blocking solution. After one hour incubation, the plates were washed three times. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma A7164) was diluted 1 in 2000 in blocking solution and 50µL was added to each well. The plates were incubated for one hour. The plates were washed three times, then OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 5 minutes later by addition of 25µL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

The results of the ELISA are shown in the Figure 158 and confirm that antibodies BPC1008, 1009 and BPC1010 bind to recombinant human IL-4. The positive control Pascolizumab also showed binding to recombinant IL-4 whereas the negative control anti IL-13 mAb and Mepolizumab showed no binding to IL-4. Antibodies BPC1009 and BPC1010 were also tested in a separate experiment which gave similar result to those shown in Figure 158.

3.1.4: IL-5 Binding ELISA

96-well high binding plates were coated with 5.9µg/ml human IL-5 (GSK) in coating buffer (0.05M bicarbonate pH9.6) and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20 (TBST). 100µL of blocking solution (1% BSA in TBST buffer) was added in each well and the plates were incubated for at least one hour at room temperature. The purified antibodies were successively diluted across the plates in blocking solution. After one hour incubation, the plates were washed three times. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma A7164) was diluted 1 in 2000 in blocking solution and 50µL was added to each well. The plates were incubated for one hour. This was washed three times, then OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 5 minutes later by addition of 25µL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.
Figure 159 shows the results of the ELISA which confirms that antibodies BPC1008 bind to recombinant human IL-5 whereas BPC1009 and BPC1010 showed no binding to IL-5. The positive control Mepolizumab also showed binding to recombinant IL-5 whereas the negative control anti IL-13 mAb and Pascolizumab showed no binding to IL-5.

**IL-13 Binding ELISA**

96-well high binding plates were coated with 5μg/ml human IL-13 (GSK) in Coating buffer (0.05M bicarbonate pH9.6, Sigma C-3041) 3 and stored overnight at 4°C. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20 (TBST). 100μL of blocking solution (1% BSA in TBST buffer) was added in each well and the plates were incubated for at least one hour at room temperature. The purified antibodies were successively diluted across the plates in blocking solution. After one hour incubation, the plates were washed three times. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma A7164) was diluted 1 in 2000 in blocking solution and 50μL was added to each well. The plates were incubated for one hour. This was washed three times, then OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 5 minutes later by addition of 25μL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

The results of the ELISA are shown in the Figure 160 and confirm that antibodies BPC1008, 1009 and BPC1010 bind to recombinant human IL-13. The positive control anti IL-13 mAb also showed binding to recombinant IL-13 whereas the negative control Pascolizumab and Mepolizumab showed no binding to IL-13. Antibodies BPC1009 and BPC1010 were also tested in a separate experiment which gave similar result to those shown in Figure 160.

**Example 32**

mAbdAbs with single domain antibodies fused onto monovalent scaffold

**32.1 Construction of mAbdAbs**

Bispecific antibodies comprising a fusion of a monovalent antibody (for further information see WO2006015371 and WO20070509782) and a domain antibody DOM-15-26-293 were constructed as follows. DNA sequences encoding the anti-c-Met Knob-into-hole heavy chain (SEQ ID NO: 202 and 203) was constructed using a PCR-based strategy followed by site directed mutagenesis. The DNA sequence encoding the anti-c-Met Unibody heavy chain (SEQ ID NO: 204) was constructed using a PCR-based strategy followed by removal of the hinge region by a PCR-based approach. Additionally, for fusion constructs, BamHI and EcoRI restriction sites were included at the C-terminus of the heavy chain expression cassette to facilitate the subsequent cloning of the anti VEGF-A domain antibody (DOM-15-26-
593) DNA sequence (encoding amino acids 455-570 of SEQ ID NO: 75) as a BamHI-
EcoRI fragment from an existing vector. The resulting expression vectors encode an
anti-VEGFA domain antibody fused onto the C-terminus of the heavy chain via a GS
linker (SEQ ID NO: 198, 199 and 201). The DNA sequence encoding the anti-c-Met
light chain (SEQ ID NO: 200) was constructed by a PCR-based strategy.

The construction of BPC1604 is described in Example 14. Table 40 below is a
summary of the monovalent scaffold mAbdAbs and antibodies that have been
generated and expressed.

32.2 Expression and purification

Expression plasmids encoding the heavy chain of BPC1017, BPC1018, BPC1019 and
BPC1020 were co-transfected into HEK 293E cells using 293fectin (Invitrogen, 12347019). A
trypotene feed was added to the cell culture the following day and the
supernatant material was harvested after about 2 to 6 days from initial transfection.
The antibodies were purified using a Protein A column before being tested in binding
assays.

32.3 HGF Receptor Binding ELISA

96-well high binding plates were coated with 5µg/ml Recombinant Human HGF R (c-
MET)/Fc Chimera (R&D system, Catalog Number: 358-MT/CF) in Coating buffer
(0.05M bicarbonate pH9.6, Sigma C-3041) and stored overnight at 4°C. The plates
were washed twice with Tris-Buffered Saline with 0.05% of Tween-20 (TBST). 100µL
of blocking solution (1% BSA in TBST buffer) was added in each well and the plates
were incubated for at least 30 minutes at room temperature. The plates were washed
three times. Then the purified antibodies were successively diluted across the plates
in blocking solution. After one hour incubation at room temp, the plates were washed three times. Goat anti-human kappa light chain specific peroxidase conjugated antibody (Sigma A7164) was diluted in blocking solution to 1 in 2000 and was added to each well. The plates were incubated for one hour. This was washed three times and then OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 5 minutes later by the addition of 25 μL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

The results of the ELISA are shown in the Figure 161 and confirm that mAbdAbs BPC1017 and BPC1018 bind to recombinant human c-MET with comparable activity to the antibodies BPC1019 and BPC1020. The negative control Pascolizumab and BPC1604 (an IGF-1 R/VEGF mAbAb) showed no binding to c-MET.

**32.4 VEGF Binding ELISA**

96-well high binding plates were coated with 0.4 μg/mL of human VEGF (GSK) in PBS and incubated at 4°C overnight. The plates were washed twice with Tris-Buffered Saline with 0.05% of Tween-20 (TBST). 100 μL of blocking solution (4% BSA in TBST buffer) was added to each well and the plates were incubated for at least one hour at room temperature. Another wash step was then performed. The purified antibodies were successively diluted across the plates in blocking solution. After one hour incubation at room temp, the plates were washed. Goat anti-human kappa light chain specific peroxidase conjugated antibody was diluted in blocking solution to 1 in 2000 and was added to each well. The plates were incubated for one hour at room temp. After another wash step, OPD (o-phenylenediamine dihydrochloride) SigmaFast substrate solution was added to each well and the reaction was stopped 5 minutes later by the addition of 25 μL of 3M sulphuric acid. Absorbance was read at 490nm using the VersaMax Tunable Microplate Reader (Molecular Devices) using a basic endpoint protocol.

Figure 162 shows the results of the ELISA which confirms that mAbdAbs BPC1017 and BPC1018 bind to recombinant human VEGF. The positive control BPC1604 also showed binding to recombinant human VEGF whereas Pascolizumab, BPC1019 and BPC1020 showed no binding to VEGF.

**Example 33**

**mAbdAbs containing the anti-IL13 dAbs DOM10-53-546 dAb and DOM10-53-567**

**33.1 Construction, expression and purification**

The anti-IL4mAb-anti-IL13dAbs shown in Table 41 were cloned and expressed transiently in HEK2936E cells, purified (as described in examples 1, 1.3 and 1.5 respectively).

Table 41
Purified PascoH-TVAAPS-546 and PascoH-TVAAPS-567 mAbdAbs were analysed by size exclusion chromatography (SEC) and sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS PAGE), under reducing conditions. The SEC and SDS PAGE data are shown in Figures 163, 164, 165 and 166.

**33.2 Biacore analysis of binding to IL-13 and IL-4**

Purified PascoH-TVAAPS-546 and PascoH-TVAAPS-567 were tested for binding to human IL-13 and human IL-4 using the BIAcore™ T100 at 25°C (as described in methods 4 and 5). These data are shown in Table 42.

</table>

The mAbdAbs tested in this assay both bound IL-4 with very high affinity (NB, for PascoH-TVAAPS-567 this was beyond the sensitivity of the machine) and with similar binding affinity to that of the anti-human IL4 mAb alone (Pascolizumab). PascoH-TVAAPS-546 and PascoH-TVAAPS-567 both bound IL-13. Note that the anti-IL-13 dAbs alone (DOM10-53-546 and DOM1-0-53-567) were not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.
These mAbdAbs were also tested for binding to cynomolgus IL-13 using the BIAcore™ T100 at 25°C (as described in method 23). These data are shown in Table 43. A mAbdAb capture level between 500 and 750 relative response units was achieved, six IL-13 concentration curves (256, 64, 16, 4, 1 and 0.25nM) were assessed for both the mAbdAbs and the anti-IL13 mAb.

Table 43

<table>

</tbody>
</table>

PascoH-TVAAPS-546 and PascoH-TVAAPS-567 both bound cynomolgus IL-13 with similar binding affinities. Note that the anti-IL-13 dAbs alone (DOM10-53-546 and DOM10-53-567) were not tested in this assay as the dAb cannot be captured onto the Protein A or anti-human IgG coated CM5 chip; instead, the anti-human IL13 mAb was used as a positive control to demonstrate IL-13 binding in this assay.

33.3 Neutralisation of human IL-13 and cynomolgus IL-13 in TF-1 cell bioassays

Purified PascoH-TVAAPS-546 and PascoH-TVAAPS-567 were tested for neutralisation of human IL-13 and cynomolgus IL-13 in TF-1 cell bioassays (as described in method 8 and method 20 respectively). Figures 167 and 168 show the neutralisation data for human IL-13 and cynomolgus IL-13 (in the TF-1 cell bioassays) respectively. DOM10-53-616 was included as a positive control for neutralisation of IL-13 in these bioassays. A dAb with specificity for an irrelevant antigen (negative control dAb) was also included as a negative control for neutralisation of IL-13. In addition, PascoH-616 and PascoH-TVAAPS-616 were also tested in these assays.

Both PascoH-TVAAPS-546 and PascoH-TVAAPS-567 fully neutralised the bioactivity of human and cynomolgus IL-13 in the TF-1 cell bioassays.

\[ \text{ND}_{50} \] values were calculated from the dataset. The \( \text{ND}_{50} \) value is the concentration of mAbdAb or mAb or dAb, which is able to neutralise the bioactivity of IL-13 by 50%. The mean \( \text{ND}_{50} \) value, the standard deviation (SD) and the number of times tested (n) are shown in Table 44.

Table 44

</table>
mAbdAbs with IgG2, IgG4 and IgG4PE heavy chain constant regions

34.1 Construction of mAbdAbs
The heavy chain constant regions of human antibody isotypes IgG2, IgG4 and a variant IgG4 (IgG4PE) genes were amplified from existing constructs by PCR and cloned using standard molecular biology techniques into an expression vector encoding the PascoH-GS-474 heavy chain (SEQ ID NO: 48). The mAbdAbs antibodies designed and tested are listed in Table 45.

</tbody>
</table>

34.2 Expression
The mAbdAbs set out in table 45 were expressed, along with PascoH-GS-474 (SEQ ID NO: 48 and 15) which is designated BPC1000. Briefly, 750 µl of HEK293 cells at 1.5x10^6 cells/ml were co-transfected with heavy and light chain expression plasmids previously incubated with 293fectin reagent (Invitrogen # 51-0031). These were placed in a shaking incubator at 37°C, 5% CO₂, and 95%RH. After 1 hour, Tryptone feeding media was added and the cells grown for a further 72 hours. Supernatant was harvested by centrifugation.

34.3 IL-4 Binding ELISA
The supernatants containing these mAbdAbs were assessed for binding to recombinant human IL-4. Briefly, ELISA plates were coated with human IL-4 (made at GSK) at 1 µg/ml and blocked with blocking solution (4% BSA in Tris buffered saline). Various dilutions of the cell supernatant, an anti IL-4 monoclonal antibody (Pascolizumab) and an antibody of irrelevant specificity (586 anti IL-13) were added.
All samples were diluted in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.

The results presented in Figure 169 show that the mAbdAbs containing the alternative isotypes all bind to human IL-4. For the mAbdAbs BPC1000, BPC1617, BPC1618 and BPC1619, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 169 is represented as a dilution factor of the neat supernatant material. For the anti-IL4 and IL-13 control antibodies, purified material was used in the assay and the starting concentration of 1µg/ml and 1µg/ml was used respectively (which is equivalent to dilution factor of 1 in Figure 169).

34.4 IL-13 Binding ELISA

The supernatants containing these mAbdAbs were assessed for binding to recombinant human IL-13. Briefly, ELISA plates were coated with human IL-13 (made at GSK) at 5µg/ml and blocked with blocking solution (4% BSA in Tris buffered saline). Various dilutions of the cell supernatant, an anti IL-13 monoclonal antibody (586) and an antibody of irrelevant specificity (Pascolizumab anti IL-4) were added. All samples were diluted in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBS + 0.05% Tween 20 (TBST). Binding was detected by the addition of a peroxidase labelled anti human kappa light chain antibody (Sigma A7164) at a dilution of 1/1000 in blocking solution. The plate was incubated for 1 hour at room temp before washing in TBST. The plate was developed by addition of OPD substrate (Sigma P9187) and colour development stopped by addition of 3M H₂SO₄. Absorbance was measured at 490nm with a plate reader and the mean absorbance plotted.

The results presented in Figure 170 show that the bispecific antibodies containing the alternative isotypes all bind to human IL-13. For the bispecific antibodies BPC1000, BPC1617, BPC1618 and BPC1619, the amount of antibody in the supernatant was not quantified thus the data presented in Figure 170 is represented as a dilution factor of the neat supernatant material. For the anti-IL4 and IL-13 control antibodies, purified material was used in the assay at a starting concentration of 1µg/ml and 1µg/ml respectively (which is equivalent to dilution factor of 1 in Figure 170).

Example 35
Alternative anti-IL-13/IL-4 mAbdAbs
35.1 Construction of anti-IL-13/IL-4 mAbdAbs with alternative variable region sequences

Using standard molecular biology techniques, DNA sequences encoding alternative heavy chain variable region anti-IL-13 mAb designated 'CV' and 'DV' were transferred from existing constructs to an expression vector containing DNA encoding the hlgG1 constant region fused to an anti IL-4 domain antibody (DOM9-1 12-210) via a TVAAPSGS linker at the c-terminus of the constant region. DNA sequences encoding alternative light chain variable region of IL-13mAbs designated 'MO' and 'NO' were assembled de novo and cloned into expression vectors containing the human Ck constant region. These alternative heavy and light chain antibody variable regions comprise the same CDR regions as the anti-IL-13 antibody described in SEQ ID NO: 12 and 13 but with an alternative humanised variable framework region.

35.2 Construction of mAbdAbs using the variable regions of the anti IL-13 mAb '656'

Using standard molecular biology techniques, a DNA sequence encoding the heavy chain variable region of the humanised anti IL-13 mAb '656', were transferred from an existing construct and cloned into an expression vector containing DNA encoding the hlgG1 constant region fused to an anti IL-4 domain antibody (DOM9-1 12-210) via a TVAAPS linker at the c-terminus of the constant region. A DNA sequence encoding the variable light region was transferred from an existing construct and cloned into an expression vector containing the human Ck constant region.

35.3 Expression of mAbdAbs

Briefly, 25 ml of HEK293 cells at 1.5x10^6 cells/ml were co-transfected with heavy and light chain expression plasmids previously incubated with 293fectin reagent (Invitrogen # 51-0031). These were placed in a shaking incubator at 37°C, 5% CO₂, and 95%RH. After 24 hours Tryptone feeding media was added and the cells grown for a further 72 hours. Supernatant was harvested by centrifugation and IgG levels quantified by ELISA. The antibodies constructed and expressed are listed in Table 46.

35.4 Binding of the mAbdAbs to IL-13

The binding activity of the mAbdAbs to IL-13 was assessed by ELISA. In brief, 5µg/ml recombinant E.coli-expressed human IL-13 (made and purified at GSK) was coated to a 96-well ELISA plate. The wells were blocked for 2 hours at room temperature, mAbdAb constructs were then titrated out down the plate. Binding was detected using a 1 in 1000 dilution of anti-human kappa light chain peroxidase conjugated antibody (catalogue number A7164, Sigma-Aldrich).

Figure 177 shows that all of the tested molecules were able to bind to human IL-13. Although BPC1615 showed binding in this ELISA it was not possible to accurately quantify the concentration of this molecule and therefore the IL-13 binding ELISA data for this molecule is not plotted in Figure 177. BPC1615 has also been shown to have high affinity binding to IL-13 in an independent Biacore assay (Table 47).

35.5 Binding of anti-IL13mAb-anti-IL4dAbs to IL-13 by Biacore™

Cell supernatants from the HEK cell transfections were also tested for binding to recombinant E.Coli-expressed human IL-13 using Biacore™ at 25°C (as described in method 4). BPC1601 was tested as a purified protein. Binding affinities, presented in Table 47, confirm that all antibodies show high affinity binding to human IL-13.
Example 36

Generation of mAbdAb with specificity for human IL-5 and human IL-13

36.1 Construction and expression of mAbdAb

A mAbdAb molecule having the heavy chain set out in SEQ ID NO: 65 and the light chain set out in SEQ ID NO: 72 was expressed in HEK293E cells. This was designated Mepolizumab-L-G4S-474 or BPC1021.

36.2 Binding of anti-IL5mAb-anti-IL13dAb to IL-5 and IL-13

This mAbdAb (in cell supernatants) was tested for binding to human IL-13 in a direct binding ELISA (as described in method 1). These data are shown in Figure 173. The sample was transfected and tested in duplicate and this has been annotated as sample A and sample B. This mAbdAb bound IL-13. Purified anti-human IL13 mAb alone was included in this assay as a positive control for IL-13 binding. Purified anti-human IL-4 mAb (Pascolizumab) and anti-human IL-5 mAb (Mepolizumab) were included as negative controls for IL-13 binding.

This mAbdAb was also tested for binding to human IL-5 in a direct binding ELISA (as described in Example 31.4) These data are illustrated in Figure 174.

Mepolizumab-L-G4S-474 bound IL-5. Purified anti-human IL4 mAb (Pascolizumab) and purified anti-human 13 mAb were included as negative controls for binding to IL-5. Purified anti-human IL5 mAb (Mepolizumab) was used as a positive control to demonstrate IL-5 binding in this assay.

257
Claims

1. An antigen-binding construct comprising a protein scaffold which is linked to one or more epitope-binding domains wherein the antigen-binding construct has at least two antigen binding sites at least one of which is from an epitope binding domain and at least one of which is from a paired VH/ VL domain.

2. An antigen-binding construct comprising at least one homodimer comprising two or more structures of formula I:

\[
\begin{align*}
(R')_m & \quad (R^6)_m \\
\downarrow & \quad \downarrow \\
(R^5)_m & \quad (R^3)_m \\
\downarrow & \quad \downarrow \\
\text{Constant} & \quad \text{Constant} \\
\text{Light chain} & \quad \text{Heavy chain} \\
\downarrow & \quad \downarrow \\
(R^2)_m & \quad (R^2)_m \\
\downarrow & \quad \downarrow \\
(R^4)_m & \quad X \\
\downarrow & \quad \downarrow \\
(R^1)_n & \quad (I)
\end{align*}
\]

wherein

- X represents a constant antibody region comprising constant heavy domain 2 and constant heavy domain 3;
- \( R^1, R^4, R^7, \) and \( R^8 \) represent a domain independently selected from an epitope-binding domain;
- \( R^2 \) represents a domain selected from the group consisting of constant heavy chain 1, and an epitope-binding domain;
- \( R^3 \) represents a domain selected from the group consisting of a paired VH and an epitope-binding domain;
- \( R^5 \) represents a domain selected from the group consisting of constant light chain, and an epitope-binding domain;
- \( R^6 \) represents a domain selected from the group consisting of a paired VL and an epitope-binding domain;
- \( n \) represents an integer independently selected from: 0, 1, 2, 3 and 4;
- \( m \) represents an integer independently selected from: 0 and 1,

wherein the Constant Heavy chain 1 and the Constant Light chain domains are associated;

wherein at least one epitope binding domain is present;
and when R³ represents a paired VH domain, R⁶ represents a paired VL
domain, so that the two domains are together capable of binding antigen.

3. An antigen-binding construct according to claim 2 wherein and R⁶
represents a paired VL and R³ represents a paired VH.

4. An antigen-binding construct according to claim 3 wherein either one or both
of R⁷ and R⁸ represent an epitope binding domain.

5. An antigen-binding construct according to any one of claims 2 to 4 wherein
either one or both of R¹ and R⁴ represent an epitope binding domain.

6. An antigen-binding construct according to any one of claims 2 to 4 wherein R⁴
is present.

7. An antigen-binding construct according to any one of claims 2 to 6 wherein R¹
R⁷ and R⁸ represent an epitope binding domain.

8. An antigen-binding construct according to any one of claims 2 to 6 wherein R¹
R⁷ and R⁸, and R⁴ represent an epitope binding domain.

9. An antigen-binding construct according to any preceding claim wherein at
least one epitope binding domain is a dAb.

10. An antigen-binding construct according to claim 9 wherein the dAb is a
human dAb.

11. An antigen-binding construct according to claim 9 wherein the dAb is a
camelid dAb.

12. An antigen-binding construct according to claim 9 wherein the dAb is a shark
dAb (NARV).

13. An antigen-binding construct according to any one of claims 1 to 8 wherein at
least one epitope binding domain is derived from a scaffold selected from
CTLA-4 (Evibody); lipocalin; Protein A derived molecules such as Z-domain of
Protein A (Affibody, SpA), A-domain (Avimer/Maxibody); Heat shock proteins
such as GroEl and GroES; transferrin (trans-body); ankyrin repeat protein
(DARPin); peptide aptamer; C-type lectin domain (Tetranectin); human γ-
crystallin and human ubiquitin (affilins); PDZ domains; scorpion toxinkunitz
type domains of human protease inhibitors; and fibronectin (adnectin).

14. An antigen-binding construct according to claim 13 wherein the epitope
binding domain is derived from a scaffold selected from an Affibody, an
ankyrin repeat protein (DARPin) and an adnectin.

15. An antigen-binding construct according to any one of claims 1 to 8 wherein
the epitope binding domain is selected from a dAb, an Affibody, an ankyrin
repeat protein (DARPin) and an adnectin.

16. An antigen-binding construct of any preceding claim wherein the binding
construct has specificity for more than one antigen.
17. An antigen-binding construct according to any preceding claim wherein the first binding site has specificity for a first epitope on an antigen and the second binding site has specificity for a second epitope on the same antigen.

18. An antigen-binding construct according to any preceding claim wherein the antigen-binding construct is capable of binding IL-13.

19. An antigen-binding construct according to any preceding claim wherein the antigen-binding construct is capable of binding two or more antigens selected from IL-13, IL-5, and IL-4.

20. An antigen-binding construct according to claim 19 wherein the antigen-binding construct is capable of binding IL-13 and IL-4 simultaneously.

21. An antigen-binding construct according to any preceding claim wherein the antigen-binding construct is capable of binding two or more antigens selected from VEGF, IGF-1 R and EGFR.

22. An antigen-binding construct according to any preceding claim wherein the antigen-binding construct is capable of binding TNF.

23. An antigen-binding construct according to claim 22 wherein the antigen-binding construct is capable of binding TNF and IL1-R.

24. An antigen-binding construct according to any one of claims 1 or claims 9 to 23 wherein the protein scaffold is an Ig scaffold.

25. An antigen-binding construct according to claim 24 wherein the Ig scaffold is an IgG scaffold.

26. An antigen-binding construct according to claim 25 wherein the IgG scaffold is selected from IgG1, IgG2, IgG3 and IgG4.

27. An antigen-binding construct according to any one of claims 1 or claims 9 to 26 wherein the protein scaffold comprises a monovalent antibody.

28. An antigen-binding construct according to any one of claims 25 to 27 wherein the IgG scaffold comprises all the domains of an antibody.

29. An antigen-binding construct according to any one of claims 9 to 12 or 15 to 28 which comprises four domain antibodies.

30. An antigen-binding construct according to claim 29 wherein two of the domain antibodies have specificity for the same antigen.

31. An antigen-binding construct according to claim 29 wherein all of the domain antibodies have specificity for the same antigen.

32. An antigen-binding construct according to any preceding claim wherein at least one of the single variable domains is directly attached to the Ig scaffold with a linker comprising from 1 to 150 amino acids.

33. An antigen-binding construct according to claim 32 wherein at least one of the single variable domains is directly attached to the Ig scaffold with a linker comprising from 1 to 20 amino acids.
34. An antigen-binding construct according to claim 33 wherein at least one of the epitope binding domains is directly attached to the Ig scaffold with a linker selected from any one of those set out in SEQ ID NO: 6 to 11 or 'GS', or any combination thereof.

35. An antigen-binding construct according to any preceding claim wherein at least one of the epitope binding domains binds human serum albumin.

36. An antigen-binding construct according to any one of claims 21 to 33 comprising an epitope binding domain attached to the Ig scaffold at the N-terminus of the light chain.

37. An antigen-binding construct according to any one of claims 21 to 33 comprising an epitope binding domain attached to the Ig scaffold at the N-terminus of the heavy chain.

38. An antigen-binding construct according to any one of claims 21 to 33 comprising an epitope binding domain attached to the Ig scaffold at the C-terminus of the light chain.

39. An antigen-binding construct according to any one of claims 21 to 33 comprising an epitope binding domain attached to the Ig scaffold at the C-terminus of the heavy chain.

40. An antigen-binding construct according to claim 1 or 2 which has 4 antigen binding sites and which is capable of binding 4 antigens simultaneously.

41. An antigen-binding construct according to any preceding claim for use in medicine.

42. An antigen-binding construct according to any preceding claim for use in the manufacture of a medicament for treating cancer or inflammatory diseases such as asthma, rheumatoid arthritis or osteoarthritis.

43. A method of treating a patient suffering from cancer or an inflammatory disease such as asthma, rheumatoid arthritis or osteoarthritis, comprising administering a therapeutic amount of an antigen-binding construct according to any preceding claim.

44. An antigen-binding construct according to any preceding claim for the treatment of cancer or inflammatory diseases such as asthma, rheumatoid arthritis or osteoarthritis.

45. A polynucleotide sequence encoding a heavy chain of an antigen binding construct according to any one of claims 1 to 40.

46. A polynucleotide encoding a light chain of an antigen binding construct according to any one of claims 1 to 40.

47. A recombinant transformed or transfected host cell comprising one or more polynucleotide sequences encoding a heavy chain and a light chain of an antigen binding construct of any preceding claim.
48. A method for the production of an antigen binding construct according to claims 1 to 40 which method comprises the step of culturing a host cell of claim 47 and isolating the antigen binding construct.

49. A pharmaceutical composition comprising an antigen binding construct of any one of claims 1 to 38 and a pharmaceutically acceptable carrier.
