Description

Field of the Invention

[0001] The present invention generally pertains to biocompatible implants for localized delivery of pharmaceutically active agents to body tissue. More particularly, the present invention pertains to biocompatible implants for localized delivery of pharmaceutically active agents to the posterior segment of the eye.

Description of the Related Art

[0002] Several diseases and conditions of the posterior segment of the eye threaten vision. Age related macular degeneration (ARMD), choroidal neovascularization (CNV), retinopathies (i.e. diabetic retinopathy, vitreoretinopathy), retinitis (i.e. cytomegalovirus (CMV) retinitis), uveitis, macular edema, and glaucoma are several examples.

[0003] Age related macular degeneration (ARMD) is the leading cause of blindness in the elderly. ARMD attacks the center of vision and blurs it, making reading, driving, and other detailed tasks difficult or impossible. About 200,000 new cases of ARMD occur each year in the United States alone. Current estimates reveal that approximately forty percent of the population over age 75, and approximately twenty percent of the population over age 60, suffer from some degree of macular degeneration. "Wet" ARMD is the type of ARMD that most often causes blindness. In wet ARMD, newly formed choroidal blood vessels (choroidal neovascularization (CNV)) leak fluid and cause progressive damage to the retina.

[0004] In the particular case of CNV in ARMD, two main methods of treatment are currently being developed, (a) photocoagulation and (b) the use of angiogenesis inhibitors. However, photocoagulation can be harmful to the retina and is impractical when the CNV is near the fovea. Furthermore, photocoagulation often results in recurrent CNV over time. Oral or parenteral (non-ocular) administration of anti-angiogenic compounds is also being tested as a systemic treatment for ARMD. However, due to drug-specific metabolic restrictions, systemic administration usually provides subtherapeutic drug levels to the eye. Therefore, to achieve effective intraocular drug concentrations, either an unacceptably high dose or repetitive conventional doses are required. Periocular injections of these compounds often result in the drug being quickly washed out and depleted from the eye, via periocular vasculature and soft tissue, into the general circulation. Repetitive intraocular injections may result in severe, often blinding, complications such as retinal detachment and endophthalmitis.

[0005] In order to prevent complications related to the above-described treatments and to provide better ocular treatment, researchers have suggested various implants aimed at localized delivery of anti-angiogenic compounds to the eye. U.S. Patent No. 5,824,072 to Wong discloses a non-biodegradable polymeric implant with a pharmaceutically active agent disposed therein. The pharmaceutically active agent diffuses through the polymer body of the implant into the target tissue. The pharmaceutically active agent may include drugs for the treatment of macular degeneration and diabetic retinopathy. The implant is placed substantially within the tear fluid upon the outer surface of the eye over an avascular region, and may be anchored in the conjunctiva or sclera; episclerally or intrasclerally over an avascular region; substantially within the suprachoroidial space over an avascular region such as the pars plana or a surgically induced avascular region; or in direct communication with the vitreous.

[0006] U.S. Patent No. 5,476,511 to Gwon et al. discloses a polymer implant for placement under the conjunctiva of the eye. The implant may be used to deliver neovascular inhibitors for the treatment of ARMD and drugs for the treatment of retinopathies, retinitis, and CMV retinitis. The pharmaceutically active agent diffuses through the polymer body of the implant.

[0007] U.S. Patent No. 5,773,019 to Ashton et al. discloses a non-bioerodable polymer implant for delivery of certain drugs including angiostatic steroids and drugs such as cyclosporine for the treatment of uveitis. Once again, the pharmaceutically active agent diffuses through the polymer body of the implant.

[0008] All of the above-described implants require careful design and manufacture to permit controlled diffusion of the pharmaceutically active agent through a polymer body (matrix devices) or polymer membrane (reservoir devices) to the desired site of therapy. Drug release from these devices depends on the porosity and diffusion characteristics of the matrix or membrane, respectively. These parameters must be tailored for each drug moiety to be used with these devices. Consequently, these requirements generally increase the complexity and cost of such implants.

[0009] U.S. Patent No. 5,824,073 to Peyman discloses an indentor for positioning in the eye. The indentor has a raised portion that is used to indent or apply pressure to the sclera over the macular area of the eye. This patent discloses that such pressure decreases choroidal congestion and blood flow through the subretinal neovascular membrane, which, in turn, decreases bleeding and subretinal fluid accumulation.

[0010] In document DE-A-40 22 553 a device is described in various embodiments for the quantitative and spatially defined and reproducible application of substances, in solution or in the form of a suspension or in the form of an ointment, to the cornea of the eye, whereby these substances are used for therapeutic, diagnostic or test purposes. This device comprises a contact lens with suitable material properties and a depression with exactly configured dimensions, which accommodates the defined volumes of the solution, suspension

or ointment, and from which the active substances or indicator substances are released in a spatially uniform and temporary controlled manner onto the area of the cornea surface that is located opposite the depression.

[0011] Therefore, a need exists in the biocompatible implant field for a surgically implantable drug delivery device capable of safe, effective, rate-controlled, localized delivery of a wide variety of pharmaceutically active agents to an outer surface of the sclera of a human eye. The surgical procedure for implanting such a device should be safe, simple, quick, and capable of being performed in an outpatient setting. Ideally, such a device should be easy and economical to manufacture. Furthermore, because of its versatility and capability to deliver a wide variety of pharmaceutically active agents, such an implant should be capable of use in clinical studies to deliver various agents that create a specific physical condition in a patient. In the particular field of ophthalmic drug delivery, such an implantable drug delivery device is especially needed for localized delivery of pharmaceutically active agents to the posterior segment of the eye to combat ARMD, CNV, retinopathies, retinitis, uveitis, macular edema, and glaucoma.

Summary of the Invention

[0012] The invention is as defined in the appended set of claims.

[0013] The present invention comprises an ophthalmic drug delivery device including a body having a scleral surface for placement proximate a sclera and a well or cavity having an opening to the scleral surface. An inner core comprising a pharmaceutically active agent is disposed in the well.

[0014] The device of the present invention may be used in a method of delivering a pharmaceutically active agent to an eye having a sclera. The device is disposed within the eye so that the pharmaceutically active agent is in communication with the sclera through the opening.

[0015] In a further aspect, the device of the present invention may be used in a method of delivering a pharmaceutically active agent to an eye having a sclera, a Tenon's capsule, and a macula.

[0016] The device is disposed on an outer surface of the sclera, below the Tenon's capsule, and proximate the macula.

Brief Description of the Drawings

[0017] For a more complete understanding of the present invention, and for further objects and advantages thereof, reference is made to the following description taken in conjunction with the accompanying drawings in which:

FIG. 1 is a side sectional view of a drug delivery device;

FIG. 2 is a side sectional view of a second drug delivery device;

FIG. 3 is a side sectional view schematically illustrating the human eye;

FIG. 4 is detailed cross-sectional view of the eye of FIG. 3 along line 4-4;

FIG. 5 is a perspective view of an ophthalmic drug delivery device according to a preferred embodiment of the present invention;

FIG. 6A is a side sectional view of the ophthalmic drug delivery device of FIG. 5;

FIG 6B is an enlarged cross-sectional view of the ophthalmic drug delivery device of FIG. 6A taken along line 6B-6B; and

FIG. 7 is a graphical illustration of the results of a pharmacokinetic study with New Zealand White rabbits implanted with the ophthalmic drug delivery device of FIGS. 5 through 6B showing the mean concentration of a pharmaceutically active agent at a target site in the retina and choroid of the rabbits as a function of time.

Detailed Description of the Preferred Embodiments

[0018] The preferred embodiments of the present invention and their advantages are best understood by referring to FIGS. 1 through 7 of the drawings, like numerals being used for like and corresponding parts of the various drawings.

[0019] FIG. 1 schematically illustrates a drug delivery device 10 helpful for understanding the present invention. Device 10 may be used in any case where localized delivery of a pharmaceutically active agent to body tissue is required. By way of example, device 10 may be used to treat a medical disorder of the eye, ear, nose, throat, skin, subcutaneous tissue, or bone. Device 10 may be used in humans or animals.

[0020] Device 10 generally includes a body 12 having an internal surface 14 and an external surface 16. As shown in FIG. 1, body 12 preferably has a generally rectangular three-dimensional geometry with a proximal end 18 and a distal end 20. Body 12 may have any other geometry that has an internal surface 14 for placement proximate a target tissue in the body of a patient. By way of example, body 12 may have a cylindrical, an oval, a square, or other polygonal three-dimensional geometry.

[0021] Body 12 includes a well or cavity 22 having an opening 24 to internal surface 14. An inner core 26 is preferably disposed in well 22. Inner core 26 is preferably a tablet comprising one or more pharmaceutically active agents. Alternatively, inner core 26 may comprise a conventional hydrogel having one or more pharmaceutically active agents disposed therein. A retaining member 28 is preferably disposed proximate opening 24. Retaining member 28 prevents inner core 26 from falling out of well 22. When inner core 26 is a cylindrical tablet, retaining member 28 is preferably a continuous rim or lip disposed circumferentially around opening 24 having a diameter slightly less than the diameter of tab-

let 26. Alternatively, retaining member 26 may comprise one or more members that extend from body 12 into opening 24. Although not shown in FIG. 1, inner core 26 may alternatively comprise a suspension, solution, powder, or combination thereof containing one or more pharmaceutically active agents. In this design internal surface 14 is formed without opening 24, and the suspension, solution, powder, or combination thereof diffuses through the relatively thin portion of internal surface 14 below inner core 26. Still further in the alternative, device 10 may be formed without well 22 or inner core 26, and the pharmaceutically active agent(s) in the form of a suspension, solution, powder, or combination thereof may be dispersed throughout body 12 of device 10. In this embodiment, the pharmaceutically active agent diffuses through body 12 into the target tissue.

[0022] The geometry of device 10 maximizes communication between the pharmaceutically active agent of inner core 26 and the tissue underlying internal surface 14. Internal surface 14 preferably physically contacts the target tissue. By way of example, if the target tissue has a generally flat surface, device 10 would be appropriate for the delivery of a pharmaceutically active agent. As another example, if the target tissue has a generally convex surface, a device 10a shown in FIG. 2 having a generally concave internal surface 14a designed to mate with such a target surface may be utilized. Comers 30 of proximal end 18a, and comers 32 of distal end 20a, may be slanted and/or rounded off to facilitate surgical placement of device 10a and to maximize comfort to the patient. Retaining member 28 is preferably designed with a minimum thickness necessary to retain inner core 26 so as to dispose a surface 26a of inner core 26 in close proximity to the target tissue. Although not shown in FIGS. I or 2, inner core 26 may be formed so that surface 26a physically contacts the target tissue.

[0023] Alternatively, device 10 or 10a may be disposed in the body of a patient so that internal surface 14 or 14a is disposed proximate the target tissue. In this case, internal surface 14 or 14a physically contacts intermediate tissue disposed between it and the target tissue. The pharmaceutically active agent of inner core 26 communicates with the target tissue through opening 24 and this intermediate tissue.

[0024] Referring again to FIG. 1, body 12 preferably comprises a biocompatible, non-bioerodable material. Body 12 more preferably comprises a biocompatible, non-bioerodable polymeric composition. Said polymeric composition may be a homopolymer, a copolymer, straight, branched, cross-linked, or a blend. Examples of polymers suitable for use in said polymeric composition include silicone, polyvinyl alcohol, ethylene vinyl acetate, polylactic acid, nylon, polypropylene, polycarbonate, cellulose, cellulose acetate, polyglycolic acid, polylactic-glycolic acid, cellulose esters, polyethersulfone, acrylics, their derivatives, and combinations thereof. Examples of suitable soft acrylics are more fully disclosed in U.S. Patent No. 5,403,901. Said polymeric composition most preferably comprises silicone. Of course, said polymeric composition may also comprise other conventional materials that affect its physical properties, including, but not limited to, porosity, tortuosity, permeability, rigidity, hardness, and smoothness. Exemplary materials affecting certain ones of these physical properties include conventional plasticizers, fillers, and lubricants. Said polymeric composition may comprise other conventional materials that affect its chemical properties, including, but not limited to, toxicity, hydrophobicity, and body 12 - inner core 26 interaction. Body 12 is preferably impermeable to the pharmaceutically active agent of inner core 26. When body 12 is made from a generally elastic polymeric composition, the diameter of well 22 may be slightly less than the diameter of inner core 26. This frictional fit secures inner core 26 within well 22. In this embodiment, body 12 may be formed without retaining member 28, if desired.

[0025] Inner core 26 may comprise any pharmaceutically active agents suitable for localized delivery to a target tissue. Examples of pharmaceutically active agents suitable for inner core 26 are anti-infectives, including, without limitation, antibiotics, antivirals, and antifungals; antiallergenic agents and mast cell stabilizers; steroidal and non-steroidal anti-inflammatory agents; combinations of anti-infective and anti-inflammatory agents; decongestants; anti-glaucoma agents, including, without limitation, adrenergics, β-adrenergic blocking agents, α-adrenergic agonists, parasypathomimetic agents, cholinesterase inhibitors, carbonic anhydrase inhibitors, and prostaglandins; combinations of anti-glaucoma agents; antioxidants; nutritional supplements; drugs for the treatment of cystoid macular edema including, without limitation, non-steroidal anti-inflammatory agents; drugs for the treatment of ARMD, including, without limitation, angiogenesis inhibitors and nutritional supplements; drugs for the treatment of herpetic infections and CMV ocular infections; drugs for the treatment of proliferative vitreoretinopathy including, without limitation, antimetabolites and fibrinolytics; wound modulating agents, including, without limitation, growth factors; antimetabolites; neuroprotective drugs, including, without limitation, eliprodil; and angiostatic steroids for the treatment of diseases or conditions of the posterior segment of the eye, including, without limitation, ARMD, CNV, retinopathies, retinitis, uveitis, macular edema, and glaucoma. Such angiostatic steroids are more fully disclosed in U.S. Patent Nos. 5,679,666 and 5,770,592. Preferred ones of such angiostatic steroids include 4,9 (11)-Pregnadien-17α,21-diol-3,20-dione and 4,9(11) -Pregnadien-17α,21-diol-3,20-dione-21-acetate. Inner core 26 may also comprise conventional non-active excipients to enhance the stability, solubility, penetrability, or other properties of the active agent or the drug core.

[0026] If inner core 26 is a tablet, it may further comprise conventional excipients necessary for tableting, such as fillers and lubricants. Such tablets may be produced using conventional tableting methods. The phar-

maceutically active agent is preferably distributed evenly throughout the tablet. In addition to conventional tablets, inner core 26 may comprise a special tablet that bioerodes at a controlled rate, releasing the pharmaceutically active agent. By way of example, such bioerosion may occur through hydrolosis or enzymatic cleavage. If inner core 26 is a hydrogel, the hydrogel may bioerode at a controlled rate, releasing the pharmaceutically active agent. Alternatively, the hydrogel may be non-bioerodable but allow diffusion of the pharmaceutically active agent.

[0027] Device 10 may be made by conventional polymer processing methods, including, but not limited to, injection molding, extrusion molding, transfer molding, and compression molding. Preferably, device 10 is formed using conventional injection molding techniques. Inner core 26 is preferably disposed in well 22 after the formation of body 12 of device 10. Retaining member 28 is preferably resilient enough to allow inner core 26 to be inserted through opening 24 and then to return to its position as shown in FIG. 1.

[0028] Device 10 is preferably surgically placed proximate a target tissue. The surgeon first makes an incision proximate the target tissue. Next, the surgeon performs a blunt dissection to a level at or near the target tissue. Once the target tissue is located, the surgeon uses forceps to hold device 10 with internal surface 14 facing the target tissue and distal end 20 away from the surgeon. The surgeon then introduces device 10 into the dissection tunnel, and positions device 10 with internal surface 14 facing the target tissue. Once in place, the surgeon may or may not use sutures to fix device 10 to the underlying tissue, depending on the specific tissue. After placement, the surgeon sutures the opening and places a strip of antibiotic ointment on the surgical wound.

[0029] The physical shape of body 12, including the geometry of internal surface 14, well 22, opening 24, and retaining member 28, facilitate the unidirectional delivery of a pharmaceutically effective amount of the pharmaceutically active agent from inner core 26 to the target tissue. In particular, the absence of a polymer layer or membrane between inner core 26 and the underlying tissue greatly enhances and simplifies the delivery of an active agent to the target tissue.

[0030] Device 10 can be used to deliver a pharmaceutically effective amount of a pharmaceutically active agent to target tissue for many years, depending on the particular physicochemical properties of the pharmaceutically active agent employed. Important physicochemical properties include hydrophobicity, solubility, dissolution rate, diffusion coefficient, and tissue affinity. After inner core 26 no longer contains active agent, a surgeon may easily remove device 10. In addition, the "pre-formed" tunnel facilitates the replacement of an old device 10 with a new device 10.

[0031] FIGS. 3 through 6B schematically illustrate an ophthalmic drug delivery device 50 according to a preferred embodiment of the present invention. Device 50 may be used in any case where localized delivery of a pharmaceutically active agent to the eye is required. Device 50 is particularly useful for localized delivery of active agents to the posterior segment of the eye. A preferred use for device 50 is the delivery of pharmaceutically active agents to the retina proximate the macula for treating ARMD, choroidial neovascularization (CNV), retinopathies, retinitis, uveitis, macular edema, and glaucoma.

[0032] Referring first to FIG. 3, a human eye 52 is schematically illustrated. Eye 52 has a cornea 54, a lens 56, a sclera 58, a choroid 60, a retina 62, and an optic nerve 64. An anterior segment 66 of eye 52 generally includes the portions of eye 52 anterior of a line 67. A posterior segment 68 of eye 52 generally includes the portions of eye 52 posterior of line 67. Retina 62 is physically attached to choroid 60 in a circumferential manner proximate pars plana 70. Retina 62 has a macula 72 located slightly lateral to its optic disk. As is well known in the ophthalmic art, macula 72 is comprised primarily of retinal cones and is the region of maximum visual acuity in retina 62. A Tenon's capsule or Tenon's membrane 74 is disposed on sclera 58. A conjunctiva 76 covers a short area of the globe of eye 52 posterior to limbus 77 (the bulbar conjunctiva) and folds up (the upper cul-de-sac) or down (the lower cul-de-sac) to cover the inner areas of upper eyelid 78 and lower eyelid 79, respectively. Conjunctiva 76 is disposed on top of Tenon's capsule 74. As is shown in FIGS. 3 and 4, and as is described in greater detail hereinbelow, device 50 is preferably disposed directly on the outer surface of sclera 58, below Tenon's capsule 74 for treatment of most posterior segment diseases or conditions. In addition, for treatment of ARMD in humans, device 50 is preferably disposed directly on the outer surface of sclera 58, below Tenon's capsule 74, with an inner core of device 50 proximate macula 72.

[0033] FIGS. 5, 6A, and 6B schematically illustrate drug delivery device 50 in greater detail. Device 50 generally includes a body 80 having a scleral surface 82 and an orbital surface 84. Scleral surface 82 is preferably designed with a radius of curvature that facilitates direct contact with sclera 58. Orbital surface 84 is designed with a radius of curvature that facilitates implantation under Tenon's capsule 74. Body 80 preferably has a curved, generally rectangular three-dimensional geometry with rounded sides 86 and 88, proximal end 90, and distal end 92. As shown best in the side sectional view of FIG. 6A, orbital surface 84 preferably has tapered surfaces 94 and 96 proximate proximal end 90 and distal end 92, respectively, that facilitate sub-Tenon implantation of device 50 and enhance the comfort of the patient. Body 80 may alternatively have a geometry similar to that of device 10a shown in FIG. 2. In addition, body 80 may have any other geometry that has a curved scleral surface 82 for contact with sclera 58. By way of example, body 80 may have a generally cylindrical, oval,

square, or other polygonal three-dimensional geometry.

[0034] Body 80 includes a well or cavity 102 having an opening 104 to scleral surface 82. An inner core 106 is preferably disposed in well 102. Inner core 106 is preferably a tablet comprising one or more pharmaceutically active agents. Alternatively, inner core 106 may comprise a conventional hydrogel having one or more pharmaceutically active agents disposed therein. A retaining member 108 is preferably disposed proximate opening 104. Retaining member 108 prevents inner core 106 from falling out of well 102. When inner core 106 is a cylindrical tablet, retaining member 108 is preferably a continuous rim or lip disposed circumferentially around opening 104 having a diameter slightly less than the diameter of tablet 106. Alternatively, retaining member 108 may comprise one or more members that extend from body 80 into opening 104.

[0035] The geometry and dimensions of device 50 maximize communication between the pharmaceutically active agent of inner core 106 and the tissue underlying scleral surface 82. Scleral surface 82 preferably physically contacts the outer surface of sclera 58. Although not shown in FIGS. 6A or 6B, inner core 106 may be formed so that surface 106a physically contacts the outer surface of sclera 58. Alternatively, scleral surface 82 may be disposed proximate the outer surface of sclera 58. By way of example, device 50 may be disposed in the periocular tissues just above the outer surface of sclera 58 or intra-lamellarly within sclera 58.

[0036] Body 80 preferably comprises a biocompatible, non-bioerodable material. Body 80 more preferably comprises a biocompatible, non-bioerodable polymeric composition. The polymeric composition comprising body 80, and the polymers suitable for use in the polymeric compositions of body 80, may be any of the compositions and polymers described hereinabove for body 12 of device 10. Body 80 most preferably is made from a polymeric composition comprising silicone. Body 80 is preferably impermeable to the pharmaceutically active agent of inner core 106. When body 80 is made from a generally elastic polymeric composition, the diameter of well 102 may be slightly less than the diameter of inner core 106. This frictional fit secures inner core 106 within well 102. In this embodiment, body 80 may be formed without retaining member 108, if desired.

[0037] Inner core 106 may comprise any ophthalmically acceptable pharmaceutically active agents suitable for localized delivery. Exemplary pharmaceutically active agents include the pharmaceutically active agents listed hereinabove for inner core 26 of device 10. Inner core 106 may also comprise conventional non-active excipients to enhance the stability, solubility, penetrability, or other properties of the active agent.

[0038] If inner core 106 is a tablet, it may further comprise conventional excipients necessary for tableting, such as fillers and lubricants. Such tablets may be produced using conventional tableting methods. The pharmaceutically active agent is preferably distributed evenly throughout the tablet. In addition to conventional tablets, inner core 106 may comprise a special tablet that bioerodes at a controlled rate, releasing the pharmaceutically active agent. By way of example, such bioerosion may occur through hydrolosis or enzymatic cleavage. If inner core 106 is a hydrogel, the hydrogel may bioerode at a controlled rate, releasing the pharmaceutically active agent. Alternatively, the hydrogel may be non-bioerodable but allow diffusion of the pharmaceutically active agent.

[0039] Device 50 may be made by conventional polymer processing methods, including, but not limited to, injection molding, extrusion molding, transfer molding, and compression molding. Preferably, device 50 is formed using conventional injection molding techniques as described hereinabove for device 10.

[0040] Device 50 is preferably surgically placed directly on the outer surface of sclera 58 below Tenon's capsule 74 using a simple surgical technique that is capable of being performed in an outpatient setting. The surgeon first performs a peritomy in one of the quadrants of eye 52. Preferably, the surgeon performs the peritomy in the infra-temporal quadrant, about 3 mm posterior to limbus 77 of eye 52. Once this incision is made, the surgeon performs a blunt dissection to separate Tenon's capsule 74 from sclera 58, forming an antero-posterior tunnel. Once the tunnel is formed, the surgeon uses forceps to hold device 50 with scleral surface 82 facing sclera 58 and distal end 92 away from the surgeon. The surgeon then introduces device 50 into the tunnel in a generally circular motion to position inner core 106 of device 50 generally above the desired portion of retina 62. The surgeon then closes the peritomy by suturing Tenon's capsule 74 and conjunctiva 76 to sclera 58. After closing, the surgeon places a strip of antibiotic ointment on the surgical wound. Alternatively, the surgeon may suture proximal end 90 of device 50 to sclera 58 to hold device 50 in the desired location before closure of the tunnel.

[0041] In the case of ARMD in the human eye, the surgeon utilizes the above-described technique to position inner core 106 of device 50 in one of two preferred locations in the infra-temporal quadrant of eye 52. One preferred location is directly on the outer surface of sclera 58, below Tenon's capsule 74, with inner core 106 positioned proximate to, but not directly above, macula 72. A surgeon may position inner core 106 of device 50 at this location by moving distal end 92 of device 50 below the inferior oblique muscle in a direction generally parallel to the lateral rectus muscle. A second preferred location is directly on the outer surface of sclera 58, below Tenon's capsule 74, with inner core 106 positioned directly above macula 72. A surgeon may position inner core 106 of device 50 at this location by moving distal end 92 of device 50 toward macula 72 along a path generally between the lateral and inferior rectus muscles and below the inferior oblique muscle. For ARMD, the pharmaceutically active agent of inner core 106 is pref-

erably one of the angiostatic steroids disclosed in U.S. Patent Nos. 5,679,666 and 5,770,592.

[0042] The physical shape of body 80 of device 50, including the geometry of scleral surface 82, well 102, opening 104, and retaining member 108, facilitate the unidirectional delivery of a pharmaceutically effective amount of the pharmaceutically active agent from inner core 106 through sclera 58, choroid 60, and into retina 62. In particular, the absence of a polymer layer or membrane between inner core 106 and sclera 58 greatly enhances and simplifies the delivery of an active agent to retina 62.

[0043] It is believed that device 50 can be used to deliver a pharmaceutically effective amount of a pharmaceutically active agent to retina 62 for many years, depending on the particular physicochemical properties of the pharmaceutically active agent employed. Important physicochemical properties include hydrophobicity, solubility, dissolution rate, diffusion coefficient, and tissue affinity. After inner core 106 no longer contains active agent, a surgeon may easily remove device 50. In addition, the "pre-formed" tunnel facilitates the replacement of an old device 50 with a new device 50.

[0044] The following example illustrates effective drug delivery to a rabbit retina using a preferred embodiment of the present invention, but is in no way limiting.

EXAMPLE

[0045] A device 50 was surgically implanted on the outer surface of the sclera, below the Tenon's capsule, generally along the inferior border of the lateral rectus muscle of the right eye of twenty (20) New Zealand White rabbits using a procedure similar to that described hereinabove for implantation of device 50 on sclera 58 of eye 52. Device 50 was constructed as shown in FIGS. 5 through 6B, with the following dimensions. Body 80 had a length 110 of about 15 mm, a width 112 of about 7.0 mm, and a maximum thickness 114 of about 1.8 mm. Retaining member 108 had a thickness 116 of about 0.15 mm. Scleral surface 82 had a radius of curvature of about 8.5 mm and an arc length of about 18 mm. Inner core 106 was a cylindrical tablet with a diameter of about 5.0 mm and a thickness of about 1.5 mm. Opening 104 had a diameter of about 3.8 mm. Well 102 had a diameter of about 4.4 mm. The pharmaceutically active agent used in tablet 106 was 4,9(11)-Pregnadien-17α,21-diol-3,20-dione, an angiostatic steroid sold by Steraloids, Inc. of Wilton, New Hampshire, and which is more fully disclosed in U.S. Patent Nos. 5,770,592 and 5,679,666. The formulation of tablet 106 consisted of 99.75 weight percent 4,9(11)-Pregnadien-17α,21-diol-3,20-dione, and 0.25 weight percent magnesium stearate.

[0046] At one week after implantation, 4 rabbits were euthanized and their right eyes were enucleated. The device 50 was removed from the eyes, and the location of tablet 106 was marked on their sclerae. Following the removal of the anterior segment and the vitreous of each eye and inversion of the thus formed eye-cup, a 10 mm diameter circular zone of retinal tissue, concentric with and below the location of tablet 106 on the sclera, was harvested (the "target site"). A 10 mm diameter circular zone of retinal tissue was also harvested from a second site located remote from the target site and on the other side of the optic nerve. In addition, a 10 mm diameter circular zone of retinal tissue was harvested from a third site located between the second site and the target site. Similar 10 mm diameter circular zones of choroidal tissue were also harvested at the target site, second site, and third site. All these tissues were separately homogenized, and the concentration of angiostatic steroid in each of these tissues was determined via an ocular pharmacokinetic study using high performance liquid chromatography and mass spectrometry analysis (LC-MS/MS). This procedure was repeated at 3, 6, 9, and 12 weeks after implantation.

[0047] FIG. 7 shows the mean concentration of 4,9(11)-Pregnadien-17α,21-diol-3,20-dione in the retina and the choroid at the target site as a function of time. The "error bars" surrounding each data point represent standard deviation. As shown in FIG. 7, device 50 delivered a pharmaceutically effective and generally constant amount of 4,9(11)-Pregnadien-17α,21-diol-3,20-dione to the retina and the choroid at the target site for a time period of up to twelve weeks. In contrast, the levels of 4,9(11)-Pregnadien-17α,21-diol-3,20-dione in the retina and the choroid at the second and third sites were at or near zero. Therefore, device 50 also delivered a localized dose of angiostatic steroid to the retina and the choroid at the target site.

[0048] From the above, it may be appreciated that the present invention provides improved devices for safe, effective, rate-controlled, localized delivery of a variety of pharmaceutically active agents to an outer surface of the sclera of a human eye. The surgical procedure for implanting such devices is safe, simple, quick, and capable of being performed in an outpatient setting. Such devices are easy and economical to manufacture. Furthermore, because of their capability to deliver a wide variety of pharmaceutically active agents, such devices are useful in clinical studies to deliver various agents that create a specific physical condition in a patient. In the particular field of ophthalmic drug delivery, such devices are especially useful for localized delivery of pharmaceutically active agents to the posterior segment of the eye to combat ARMD, CNV, retinopathies, retinitis, uveitis, macular edema, and glaucoma.

[0049] It is believed that the operation and construction of the present invention will be apparent from the foregoing description. While the apparatus shown or described above have been characterized as being preferred, various changes and modifications may be made therein without departing from the scope of the invention as defined in the following claims.

Claims

1. An ophthalmic drug delivery device (50), comprising:

   a body (80) having:

   a scleral surface (82) having a radius of curvature that facilitates contact with a sclera (58) of a human eye (52);
   a well (102) having an opening (104) to said scleral surface; and
   a geometry that facilitates disposing said device on an outer surface of said sclera, below a Tenon's capsule (74) of said eye, and in a posterior segment (68) of said eye; and

   an inner core (106) disposed in said well and comprising a pharmaceutically active agent.

2. The ophthalmic drug delivery device of claim 1, wherein said body has a geometry that facilitates disposing said device on said outer surface of said sclera, below said Tenon's capsule, and in said posterior segment so that said inner core is disposed proximate a macula (72) of said eye.

3. The ophthalmic drug delivery device of claim 2, wherein said body has a geometry that facilitates disposing said device on said outer surface of said sclera, below said Tenon's capsule, and in said posterior segment so that said inner core is disposed generally above said macula.

4. The ophthalmic drug delivery device of claim 1, wherein said inner core is a tablet.

5. The ophthalmic drug delivery device of claim 4, wherein at least a portion of said body is made from a generally elastic material so that said generally elastic material, a geometry of said well, and a geometry of said tablet frictionally secure said tablet within said well.

6. The ophthalmic drug delivery device of claim 4, wherein said tablet is formulated to bioerode and release said pharmaceutically active agent at a controlled rate.

7. The ophthalmic drug delivery device of claim 1, wherein said inner core is a hydrogel.

8. The ophthalmic drug delivery device of claim 7, wherein said hydrogel is formulated to bioerode and release said pharmaceutically active agent at a controlled rate.

9. The ophthalmic drug delivery device of claim 7, wherein said pharmaceutically active agent diffuses through said hydrogel at a controlled rate.

10. The ophthalmic drug delivery device of claim 1, further comprising a retaining member (108) extending from said body proximate said opening, and wherein said retaining member helps to retain said inner core in said well.

11. The ophthalmic drug delivery device of claim 10, wherein said retaining member comprises a rim at least partially disposed around said opening.

12. The ophthalmic drug delivery device of any one of claims 1 to 11, wherein said pharmaceutically active agent comprises a compound selected from the group consisting of 4,9(11)-Pregnadien-17α,21-diol-3,20-dione and 4,9(11)-Pregnadien-17α,21-diol-3,20-dione-21 -acetate.

13. The ophthalmic drug delivery device of any one of claims 1-11, wherein said pharmaceutically active agent comprises eliprodil.

Patentansprüche

1. Ophtalmische Arznei-Abgabe-Vorrichtung (50), umfassend:

   einen Körper (80) mit:

   einer skleralen Oberfläche (82) mit einem den Kontakt mit der Sklera (58) eines menschlichen Auges (52) erleichternden Krümmungsradius;
   einem Topf (102) mit einer zur skleralen Oberfläche gewandten Öffnung (104);
   einer Geometrie, die eine Anordnung der Vorrichtung an einer äußeren Oberfläche der Sklera unter der Tenonkapsel (74) des Auges und in einem hinteren Segment (68) des Auges erleichtert; und

   einem im Topf angeordneten inneren Kern (106), der einen pharmazeutisch aktiven Wirkstoff umfaßt.

2. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 1, wobei der Körper eine Geometrie umfaßt, die eine Anordnung der Vorrichtung auf der äußeren Oberfläche der Sklera unter der Tenonkapsel und im hinteren Segment erleichtert, so daß der innere Kern neben der Makula (72) des Auges angeordnet ist.

3. Ophalmische Arznei-Abgabe-Vorrichtung nach An-

spruch 2, wobei der Körper eine Geometrie umfaßt, die eine Anordnung der Vorrichtung auf der äußeren Oberfläche der Sklera unter der Tenonkapsel und im hinteren Segment erleichtert, so daß der innere Kern im Allgemeinen über der Makula angeordnet ist.

4. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 1, wobei der innere Kern eine Tablette ist.

5. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 4, wobei zumindest ein Teil des Körpers aus einem im allgemeinen elastischen Material hergestellt ist, so daß die Tablette durch das im allgemeinen elastische Material, die Geometrie des Topfes und die Geometrie der Tablette reibschlüssig im Topf gehalten ist.

6. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 4, wobei die Tablette für eine Bio-Erosion und Freigabe des pharmazeutisch aktiven Wirkstoffes mit einer kontrollierten Rate formuliert ist.

7. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 1, wobei es sich bei dem inneren Kern um ein Hydrogel handelt.

8. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 7, wobei das Hydrogel für eine Bio-Erosion und Freigabe des pharmazeutisch aktiven Wirkstoffes mit einer kontrollierten Rate formuliert ist.

9. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 7, wobei der pharmazeutisch aktive Wirkstoff mit einer kontrollierten Rate durch das Hydrogel diffundiert.

10. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 1, die des weiteren ein Halteelement (108) umfaßt, das sich vom Körper neben der Öffnung erstreckt und den Halt des inneren Kerns im Topf unterstützt.

11. Ophtalmische Arznei-Abgabe-Vorrichtung nach Anspruch 10, wobei das Halteelement einen zumindest teilweise um die Öffnung angeordneten Rand aufweist..

12. Ophtalmische Arznei-Abgabe-Vorrichtung nach einem der Ansprüche 1-11, wobei der pharmazeutisch aktive Wirkstoff eine Verbindung, ausgewählt aus der Gruppe, bestehend aus 4,9 (11)-pregnadien-17α, 21-diol-3,20-dion und 4,9 (11)-pregnadien-17α, 21-diol-3,20-dion-21-acetat umfaßt.

13. Ophtalmische Arznei-Abgabe-Vorrichtung nach einem der Ansprüche 1-11, wobei der pharmazeutisch aktive Wirkstoff Eliprodil umfaßt.

Revendications

1. Dispositif d'administration de médicaments ophtalmiques (50), comportant :

   un corps (80) ayant :

   une surface sclérale (82) ayant un rayon de courbure qui facilite le contact avec une sclérotique (58) d'un oeil humain (52),
   un puits (102) ayant une ouverture (104) sur ladite surface sclérale, et
   une géométrie qui facilite le positionnement dudit dispositif sur une surface extérieure de ladite sclérotique, en dessous d'une capsule de Tenon (74) dudit oeil, et dans un segment postérieur (68) dudit oeil, et

   un noyau intérieur (106) disposé dans ledit puits et comportant un agent pharmaceutiquement actif.

2. Dispositif d'administration de médicaments ophtalmiques selon la revendication 1, dans lequel ledit corps a une géométrie qui facilite le positionnement dudit dispositif sur ladite surface extérieure de ladite sclérotique, en dessous de ladite capsule de Tenon, et dans ledit segment postérieur de sorte que ledit noyau intérieur est disposé à proximité d'une macula (72) dudit oeil.

3. Dispositif d'administration de médicaments ophtalmiques selon la revendication 2, dans lequel ledit corps a une géométrie qui facilite le positionnement dudit dispositif sur ladite surface extérieure de ladite sclérotique, en dessous de ladite capsule de Tenon, et dans ledit segment postérieur de sorte que ledit noyau intérieur est disposé d'une manière générale au-dessus de ladite macula.

4. Dispositif d'administration de médicaments ophtalmiques selon la revendication 1, dans lequel ledit noyau intérieur est une tablette.

5. Dispositif d'administration de médicaments ophtalmiques selon la revendication 4, dans lequel au moins une partie dudit corps est constituée d'une matière de manière générale élastique de sorte que ladite matière de manière générale élastique, une géométrie dudit puits, et une géométrie de ladite tablette ajustent par frottement ladite tablette dans ledit puits.

6. Dispositif d'administration de médicaments ophtal-

miques selon la revendication 4, dans lequel ladite tablette est formulée pour effectuer une bio-érosion et une libération dudit agent pharmaceutiquement actif à un débit commandé.

7. Dispositif d'administration de médicaments ophtalmiques selon la revendication 1, dans lequel ledit noyau intérieur est un hydrogel.

8. Dispositif d'administration de médicaments ophtalmiques selon la revendication 7, dans lequel ledit hydrogel est formulé pour effectuer une bio-érosion et une libération dudit agent pharmaceutiquement actif à un débit commandé.

9. Dispositif d'administration de médicaments ophtalmiques selon la revendication 7, dans lequel ledit agent pharmaceutiquement actif se diffuse à travers ledit hydrogel à un débit commandé.

10. Dispositif d'administration de médicaments ophtalmiques selon la revendication 1, comportant en outre un élément de retenue (108) s'étendant à partir dudit corps à proximité de ladite ouverture, et dans lequel ledit élément de retenue aide à retenir ledit noyau intérieur dans ledit puits.

11. Dispositif d'administration de médicaments ophtalmiques selon la revendication 10, dans lequel ledit élément de retenue comporte un rebord au moins partiellement disposé autour de ladite ouverture.

12. Dispositif d'administration de médicaments ophtalmiques selon l'une quelconque des revendications 1 à 11, dans lequel ledit agent phar maceutiquement actif comporte un composé sélectionné parmi le groupe constitué de 4,9(11)-Pregnadicne-17α, 21-diol-3,20-dione et 4,9(11)-Pregnadiene-17α,21 -diol-3,20-dione-21-acétate.

13. Dispositif d'administration de médicaments ophtalmiques selon l'une quelconque des revendications 1 à 11, dans lequel ledit agent pharmaceutiquement actif comporte l'eliprodil.
