ABSTRACT

An organic material production system includes: a pretreatment device (12) that pulverizes a biomass material (11); a hydrothermal decomposition apparatus (14) that hydrothermally decomposes a pulverized biomass (13) by causing it to countercurrently contact with hot compressed water (15), elutes lignin components and hemicellulose components into the hot compressed water (15), and separates the lignin components and the hemicellulose components from a biomass solid residue; a first enzymatic hydrolysis device (19-1) that treats cellulose in a biomass solid residue (17), discharged from the hydrothermal decomposition apparatus, with an enzyme (18) to enzymatically hydrolyze it to a sugar solution containing hexose; a fermenter (21) that produces ethanol by fermentation using a sugar solution (20) obtained by the first enzymatic hydrolysis device (19-1); and a refiner 25 that refines an alcohol fermentation liquid (22), so as to separate it into ethanol (23) and a residue (24).
DESCRIPTION

ORGANIC MATERIAL PRODUCTION SYSTEM USING BIOMASS MATERIAL AND METHOD

5

TECHNICAL FIELD

[0001] The present invention relates to a biomass hydrothermal decomposition apparatus and a method thereof that enable efficient hydrothermal decomposition of biomass material, and to an organic material production system using biomass material, which system enables efficient production of organic materials such as alcohols, substitutes for petroleum, or amino acids by using such apparatus and method.

15

BACKGROUND ART

[0002] Technologies for producing ethanol or the like have been commercialized that involve converting woody biomass or other biomass into sugars with dilute sulfuric acid or concentrated sulfuric acid, and then subjecting them to solid-liquid separation, neutralizing the liquid phase thereof, and utilizing the resultant components as biomass materials for ethanol fermentation or the like (Patent Documents 1 and 2). Further, by using sugar as starting material, production of chemical industrial raw material (e.g., lactic fermentation) has been considered. Biomass as used herein refers to a living organism integrated in material circulation in the global biosphere or accumulation of organic materials derived from living organisms (see JIS K 3600 1258).

25

[0003] Sugarcane, corn, and other materials, currently used as alcohol raw materials, have been originally used for food. Using such food resources as long-term stable
industrial resources is not preferable in view of life cycle of valuable food.

[0004] For this reason, it is a challenge to efficiently use cellulose resources such as herbaceous biomass and woody biomass, which are considered as potentially useful resources.

[0005] Cellulose resources include cellulose ranging from 38% to 50%, hemicelluloses components ranging from 23% to 32%, and lignin components, which are not used as fermentation materials, ranging from 15% to 22%. Due to many challenges, the industrial studies have been conducted targeting certain fixed materials, and no technologies have been disclosed yet on production systems taking into account diversity of the materials.

[0006] Production systems targeting fixed materials see almost no point regarding countermeasures for waste problems and global warming, because those systems have attempted such countermeasures with a method that brings more disadvantages to fermentation materials than starch materials. Thus, there has been a need for a method applicable to a variety of wastes in broader sense. Enzymatic saccharification methods are also considered as a future challenge due to its low efficiency. Acid treatment only achieves a low saccharification rate of about 75% (a basis for components that can be saccharified), due to excessive decomposition of sugar. Thus, the ethanol yield achieves only 25% by weight of cellulose resources (Non-Patent Document 1 and Patent Document 3).

No. 2005-168335

DISCLOSURE OF INVENTION

[0008] In the proposals disclosed in Patent Documents 1 and 2 above, sulfuric acid necessary for reaction needs to be constantly supplied from outside the reaction system. With increasing the production scale, this poses problems, such as increasing the cost for purchasing equipment resistant to the acid and large amounts of sulfuric acid, while increasing the cost for disposing used sulfuric acid (e.g., cost for processing with a gypsum desulphulation), and the cost for recovering such sulfuric acid.

[0009] The proposal disclosed in Patent Document 3 above involves subjecting various types of cellulose resources to hydrothermal treatment, and converting them into sugars with enzymatic saccharification. During the hydrothermal treatment, cellulase inhibitors such as lignin components (Non-Patent Document 2) that inhibit enzymatic saccharification of cellulose are not removed and mixed with cellulose. This poses a problem of reducing the efficiency in cellulose enzymatic saccharification.

[0010] Other than cellulose, hemicellulose components are also contained in cellulose resources. This poses a problem that enzymes suitable for cellulose and hemicellulose components are necessary for enzymatic saccharification.
[0011] The resulting sugar solution includes a hexose solution from cellulose, and a pentose solution from hemicellulose components. For example, for alcohol fermentation, yeasts suitable for the respective solutions are necessary. Thus, alcohol fermentation needs to be improved low efficiency for fermenting a mixture of a hexose solution and a pentose solution.

[0012] As such, conventional technologies have caused a phenomenon that side reaction products inhibit enzymatic saccharification, reducing the sugar yield. Thus, what has been needed is a hydrothermal decomposition apparatus that removes inhibitors for enzymatic saccharification and thereby improves enzymatic saccharification of cellulose-based components.

[0013] The present invention provides an organic material production system using biomass material, which can efficiently produce a sugar solution using such apparatus and method, and can efficiently produce various types of organic materials (e.g., alcohols, substitutes for petroleum, or amino acids) using the sugar solution as a base material.

[0014] According to a first aspect of the present invention, an organic material production system using biomass material includes: a hydrothermal decomposition apparatus that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component
and the hemicellulose component from a biomass solid residue; a first enzymatic hydrolysis device that treats, with an enzyme, cellulose in the biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and a fermenter that produces, using the sugar solution obtained by the first enzymatic hydrolysis device, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.

[0014a] In one embodiment, the present invention relates to an organic material production system using biomass material, the organic material production system comprising: a hydrothermal decomposition apparatus that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component and the hemicellulose component from a biomass solid and obtain a cellulose-based biomass solid residue; a first enzymatic hydrolysis device that treats, with an enzyme, cellulose in the cellulose-based biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and a fermenter that produces, using the sugar solution obtained by the first enzymatic hydrolysis device, any one of alcohols, substitutes for petroleum, or amino acids by fermentation, wherein the hydrothermal decomposition apparatus has a reaction temperature ranging from 180°C to 240°C.
According to a second aspect, the organic material production system according to the first aspect further includes: a second enzymatic hydrolysis device that treats, with an enzyme, the hemicellulose component in discharged hot water, so as to hydrolyze the hemicellulose component to a sugar solution containing pentose; and a fermenter that produces, using the sugar solution obtained by the second enzymatic hydrolysis device, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.

According to a third aspect, in the organic material production system according to the first or second aspects, the hydrothermal decomposition apparatus has a reaction temperature ranging from 180°C to 240°C.

According to a forth aspect, a method for organic material production using biomass material includes: a hydrothermal decomposition process that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component and the hemicellulose component from a biomass solid residue; a first enzymatic hydrolysis process that treats, with an enzyme, cellulose in the biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and a fermentation process that produces, using the sugar solution obtained by the first enzymatic hydrolysis process, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.
[0017a] In one embodiment, the present invention relates to an organic material production method using biomass material, the organic material production method comprising: a hydrothermal decomposition process that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component and the hemicellulose component from a biomass solid and obtain a cellulose-based biomass solid residue, the hydrothermal decomposition process being performed in a hydrothermal decomposition apparatus; a first enzymatic hydrolysis process that treats, with an enzyme, cellulose in the cellulose-based biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and a fermentation process that produces, using the sugar solution obtained by the first enzymatic hydrolysis process, any one of alcohols, substitutes for petroleum, or amino acids by fermentation, wherein the hydrothermal decomposition apparatus has a reaction temperature ranging from 180°C to 240°C.

[0018] According to a fifth aspect, the method for organic material production according to the forth aspect further includes: a second enzymatic hydrolysis process that treats, with an enzyme, the hemicellulose component in discharged hot water, so as to hydrolyze the hemicellulose component to a sugar solution containing pentose; and a fermentation process that produces, using the sugar solution obtained by the second enzymatic hydrolysis process, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.
According to a sixth aspect, in the method for organic material production according to the forth or fifth aspects, the hydrothermal decomposition process has a reaction temperature ranging from 180°C to 240°C.

5 EFFECT OF THE INVENTION

According to the present invention, with use of a hydrothermal decomposition apparatus that causes countercurrent contact, side reaction products (lignin components and hemicellulose components) resulting from the reaction for producing a target component, i.e., cellulose, (that is enzymatically saccharified to a hexose solution) are transferred into the hot compressed water. In this way, the cellulose-based biomass solid residue can be obtained. Accordingly, by efficiently saccharifying it to the hexose solution and using the sugar solution as a base material,
various types of organic materials (e.g., alcohols, substitutes for petroleum, or amino acids) can be produced efficiently.

[0021] By causing biomass material and hot compressed water to countercurrently contact with each other, their components are sequentially discharged to the outside the reaction system in order of solubility in the hot water. Further, due to the temperature gradient from a feeding section of the biomass to a feeding section of the hot water, excessive decomposition of hemicellulose components is prevented. As a result, pentose components can be recovered efficiently.

BEST MODE(S) FOR CARRYING OUT THE INVENTION
[0024] Exemplary embodiments of the present invention are described with reference to the accompanying drawings. The present invention is not limited to the embodiments.
10 Constituting elements in the embodiments include elements easily achieved by a person skilled in the art, or elements being substantially equivalent to those elements.
First Embodiment
[0025] A system of producing an organic material, i.e., alcohol, with use of biomass material according to an embodiment of the present invention is described with reference to the drawings. Fig. 1 is a schematic of an organic material production system using biomass material according to the embodiment. As shown in Fig. 1, an alcohol production system 10-1 using biomass material according to the present embodiment includes: a pretreatment device 12 that, for example, pulverizes the biomass material 11; a hydrothermal decomposition apparatus 14 that hydrothermally decomposes pretreated biomass material (e.g., straw in the present embodiment), i.e., a pulverized biomass 13, by causing it to countercurrently contact the hot compressed water 15, elutes lignin components and hemicellulose components into the hot compressed water 15, and separates the lignin components and the hemicellulose components from a biomass solid residue; a first enzymatic hydrolysis device 19-1 that treats cellulose in a biomass solid residue 17, discharged from the hydrothermal decomposition apparatus 14, with an
enzyme (cellulase) 18 to enzymatically hydrolyze it to a sugar solution containing hexose; a first alcohol fermenter 21-1 that produces an alcohol (ethanol in the present embodiment) by fermentation using a first sugar solution (hexose solution) 20-1 obtained by the first enzymatic hydrolysis device 19-1; and a first refiner 25-1 that refines a first alcohol fermentation liquid 22-1, so as to separate it into a target product, i.e., ethanol 23, and a residue 24. From the hydrothermal decomposition apparatus 14, the hot compressed water, into which the lignin components and the hemicellulose components are eluted, is discharged as discharged hot water 16.

[0026]  Biomass to be fed to the hydrothermal decomposition apparatus 14 is not limited to any specific type, and is a living organism integrated in material circulation in global biosphere or accumulation of organic materials derived from living organisms (see JIS K 3600 1258). In the present invention, particularly, cellulose resources of wood materials such as broadleaf trees and plant materials; agricultural wastes; and food wastes are preferably used.

[0027]  The biomass material 11 is preferably broken into particles having a diameter of equal to or less than 5 millimeters, though not limited to this particle diameter. The present embodiment describes the pretreatment device 12 as an example of pulverizing equipment. The present invention is not limited to this example, and for example, cleaning equipment may be used as the pretreatment device 12. When the biomass material 11 is chaff for example, the biomass material 11 can be fed to the hydrothermal decomposition apparatus 14, without being subjected to pulverization with pulverizing equipment.

[0028]  In the hydrothermal decomposition apparatus 14,
the reaction temperature ranges from 180°C to 240°C preferably, and from 200°C to 230°C more preferably. This is because, at temperatures below 180°C, the hydrothermal decomposition takes place at a low rate and requires a longer time, increasing the apparatus size, which are not preferable. On the contrary, at temperatures above 240°C, the decomposition rate is too high and more cellulose components are transferred from the solid to the liquid, facilitating excessive decomposition of hemicellulose sugars, which are not preferable. Dissolution of cellulose components starts at about 140°C, dissolution of cellulose starts at about 230°C, and dissolution of lignin components starts at about 140°C. The temperature is preferably set within a range from 180°C to 240°C that allows cellulose to be remained in the solid, and that enables hemicellulose components and lignin components to be decomposed at adequate rates.

[0029] The reaction pressure is preferably set to a pressure higher by 0.1 MPa to 0.5 MPa than the saturated steam pressure of water at each temperature, which allows the hot compressed water to stay inside the body. The reaction time is preferably three minutes to ten minutes, not more than 20 minutes. This is because a longer reaction time increases the ratio of excessively decomposed products and is not preferable.

[0030] According to the present invention, for the flowage of the hot compressed water 15 and the flowage of the pulverized biomass 13 inside the device main body of the hydrothermal decomposition apparatus 14, the hot compressed water 15 and the pulverized biomass 13 are countercurrently contacted, preferably with stirred and flowed.

[0031] In the hydrothermal decomposition apparatus 14,
the pulverized biomass 13 is fed from the left side in the figure, while the hot compressed water 15 is fed from the right side in the figure. Because the pulverized biomass 13 and the hot compressed water 15 move in an opposite direction to one another, the hot compressed water 15 (hot water, the liquid dissolving decomposed products) is moved while being soaked in solid particles by the counter-current flow against the solid, the biomass material 11. [0032] When countercurrently contacting each other, the solid biomass material 11 is decomposed with the hot compressed water 15, and the resulting decomposed products are dissolved and transferred to the hot compressed water 15.

[0033] As a ratio of the solid to the liquid, the liquid ratio is preferably less, because it enables reduction in amount of water to be recovered and in amount of steam used for warming during the hydrothermal decomposition. The weight ratio of the biomass material and the hot compressed water both to be fed is, for example, 1:1 to 1:10 preferably, and 1:1 to 1:5 more preferably, though it varies accordingly depending on the apparatus configuration.

[0034] According to the present invention, in the hydrothermal decomposition apparatus 14, use of the counter-current flow transfers lignin components and hemicellulose components to the liquid, i.e., the hot compressed water 15, while allowing cellulose to remain in the solid, i.e., the biomass solid residue 14. In this way, the first sugar solution (hexose) 20 is obtained at the first enzymatic hydrolysis device 19-1. Accordingly, it is possible to establish a fermentation process suitable for a hexose (fermentation suitable for an end product: in the present embodiment, the ethanol 23 is obtained by fermentation using the first alcohol fermenter 21-1, and
refined to the first alcohol fermentation liquid 22-1). [0035] According to the present invention, with use of a hydrothermal decomposition apparatus that causes counter-current contact, side reaction products (lignin components and hemicellulose components) resulting from the reaction for producing a target component, i.e., cellulose, (that is enzymatically saccharified to a hexose solution) are transferred into the hot compressed water. In this way, the cellulose-based biomass solid residue can be obtained. Accordingly, by efficiently saccharifying the cellulose and using the sugar solution as a base material, various types of organic materials (e.g., alcohols) can be produced efficiently.

[0036] By causing counter-current contact, their components are sequentially discharged in order of solubility in the hot compressed water. Further, due to the temperature gradient from where the biomass is fed to where the hot water is fed, excessive decomposition of hemicellulose components is prevented. As a result, pentose components can be recovered efficiently. Further, by causing the biomass material and the hot compressed water to countercurrently contact with each other, the heat is recovered, which is preferable in view of system efficiency.

[0037] Although the present embodiment describes an example that an alcohol, ethanol, is obtained by fermentation, the present invention is not limited to this example. Other than alcohols, substitutes for petroleum used as chemical product material, or amino acids used as food and feed materials can be obtained with a fermenter.

[0038] Examples of industrial products produced from a sugar solution as a base material may include liquefied petroleum gas (LPG), auto fuel, aircraft jet fuel, heating
oil, diesel oil, various types of heavy oils, fuel gas, naphtha, and naphtha decomposed products such as ethylene glycol, ethanolamine, alcohol ethoxylate, vinyl chloride polymer, alkylaluminum, polyvinyl acetate (PVA), vinyl acetate emulsion, polystyrene, polyethylene, polypropylene, polycarbonate, methyl methacrylate (MMA) resin, nylon, and polyester. Thus, substitutes for industrial products derived from crude oil, which is fossil fuel, and sugar solution derived from biomass, which is a material for producing such substitutes, can be used efficiently.

Second Embodiment

[0039] With reference to the drawings, the following describes a system of producing an organic material, i.e., alcohol, with use of biomass material according to an embodiment of the present invention. Fig. 2 is a schematic of an organic material production system using biomass material according to the present embodiment. As shown in Fig. 2, an alcohol production system 10-2 using biomass material according to the present embodiment is constituted by the system 10-1 shown in Fig. 1 that includes a second enzymatic hydrolysis device 19-2. The second enzymatic hydrolysis device 19-2 treats hemicellulose components, eluted into the discharged hot water 16 discharged from the hydrothermal decomposition apparatus 14, with an enzyme to enzymatically hydrolyze it to a second sugar solution 20-2 containing pentose. Two enzymatic hydrolysis devices, two alcohol fermenters, and two refiners are provided (the first enzymatic hydrolysis device 19-1, the second enzymatic hydrolysis device 19-2, the first alcohol fermenter 21-1, a second alcohol fermenter 21-2, the first refiner 25-1, and a second refiner 25-2). The ethanol 23 is obtained by performing an enzymatic hydrolysis process, an alcohol fermentation process, and an alcohol refining
process that are suitable for each of the first sugar solution (hexose) 20-1 and the second sugar solution (pentose) 20-2.

[0040] In the present embodiment, the ethanol 23 can be produced by fermentation, using the second sugar solution (pentose) 20-2 obtained by the second enzymatic hydrolysis device 19-2.

[0041] The discharged hot water is not necessarily treated in a separate system. For example, a process subsequent to that performed at the enzymatic hydrolysis device, a process subsequent to that performed at the alcohol fermenter, or a process subsequent to that performed at the refiner may be arranged as common process, or other modification may be made appropriately.

[0042] According to the present invention, in the hydrothermal decomposition apparatus 14, use of the counter-current flow allows cellulose to remain in the solid phase which is the biomass solid residue 17. Accordingly, the first sugar solution (hexose) 20-1 is obtained by the first enzymatic hydrolysis device 19-1 for performing enzymatic hydrolysis. Further, hemicellulose components dissolved in the liquid phase which is the hot compressed water 15, are separated as the discharged hot water 16, and the second sugar solution (pentose) 20-2 is obtained by the second enzymatic hydrolysis device 19-2 for performing another enzymatic hydrolysis. This enables the first sugar solution and the second sugar solution to be separated efficiently and saccharified in different processes. Accordingly, fermentation processes suitable for hexose and pentose (fermentation suitable for an end product: e.g., ethanol fermentation) can be established.

[0043] As such, in the hydrothermal decomposition apparatus 14, use of the counter-current flow transfers a
side reaction product and a lignin component soluble hot compressed water, both acting as inhibitors during enzymatic saccharification reaction for obtaining hexose, to the hot compressed water 15. Accordingly, the cellulose-based biomass solid residue 17 is obtained, improving the yield of pentose in the subsequent saccharification reaction.

[0044] On the other hand, hemicellulose components contained in the separated discharged hot water 16 is saccharified later at the second enzymatic hydrolysis device 19-2, so that a sugar solution containing pentose can be obtained. Then, in the first and second alcohol fermenters 18, 34 by using yeasts etc. suitable for hexose and pentose, ethanol can be obtained by fermentation individually and efficiently.

[0045] As described above, the present invention provides: an organic material production system and a method using biomass material that can produce, by transferring cellulose-based components and hemicellulose components from the biomass material to the hot compressed water and separating them from each other, sugar solutions suitable for the cellulose-based components and the hemicellulose components (hexose sugar solution and pentose sugar solution), and that can efficiently produce, using the sugar solutions as base materials, various types of organic materials (e.g., alcohols, substitutes for petroleum, or amino acids). However, a conventional technology causes a phenomenon that a side reaction product inhibits enzymatic saccharification and a sugar yield is reduced.

INDUSTRIAL APPLICABILITY

[0046] As described, the system and method according to
the present invention can separate cellulose-based components from biomass material, so as to efficiently produce a sugar solution. Further, using the sugar solution as a base material, various types of organic materials (e.g., alcohols, substitutes for petroleum, or amino acids) can be efficiently produced.
CLAIMS:

1. An organic material production system using biomass material, the organic material production system comprising:

   a hydrothermal decomposition apparatus that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component and the hemicellulose component from a biomass solid and obtain a cellulose-based biomass solid residue;

   a first enzymatic hydrolysis device that treats, with an enzyme, cellulose in the cellulose-based biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and

   a fermenter that produces, using the sugar solution obtained by the first enzymatic hydrolysis device, any one of alcohols, substitutes for petroleum, or amino acids by fermentation,

   wherein the hydrothermal decomposition apparatus has a reaction temperature ranging from 180°C to 240°C.

2. The organic material production system according to claim 1, further comprising:

   a second enzymatic hydrolysis device that treats, with an enzyme, the hemicellulose component in discharged hot
water, so as to hydrolyze the hemicellulose component to a sugar solution containing pentose; and

a fermenter that produces, using the sugar solution obtained by the second enzymatic hydrolysis device, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.

3. An organic material production method using biomass material, the organic material production method comprising:

a hydrothermal decomposition process that causes the biomass material and hot compressed water to countercurrently contact with each other and undergo hydrothermal decomposition, and that transfers a lignin component and a hemicellulose component into the hot compressed water, so as to separate the lignin component and the hemicellulose component from a biomass solid and obtain a cellulose-based biomass solid residue, the hydrothermal decomposition process being performed in a hydrothermal decomposition apparatus;

a first enzymatic hydrolysis process that treats, with an enzyme, cellulose in the cellulose-based biomass solid residue discharged from the hydrothermal decomposition apparatus, so as to enzymatically hydrolyze the cellulose to a sugar solution containing hexose; and

a fermentation process that produces, using the sugar solution obtained by the first enzymatic hydrolysis process, any one of alcohols, substitutes for petroleum, or amino acids by fermentation,

wherein the hydrothermal decomposition apparatus has a reaction temperature ranging from 180°C to 240°C.
4. The organic material production method according to claim 3, further comprising:

a second enzymatic hydrolysis process that treats, with an enzyme, the hemicellulose component in discharged hot water, so as to hydrolyze the hemicellulose component to a sugar solution containing pentose; and

a fermentation process that produces, using the sugar solution obtained by the second enzymatic hydrolysis process, any one of alcohols, substitutes for petroleum, or amino acids by fermentation.
