Description

BACKGROUND OF THE INVENTION

a) Field of the Invention

The present invention relates to a tone signal synthesizer using a delayed feedback type tone signal synthesizing algorithm for synthesizing a tone signal by waveform processing through inputting a driving waveform signal into a closed loop containing a delay means and a filter means and circulating the driving waveform signal in the closed loop. In particular, it relates to a tone signal synthesizer adapted for an electronic musical instrument capable of providing tone control to simulate musical tones of natural musical instruments.

b) Description of the Prior Art

In a waveform read type tone signal synthesizer, tone signals different in pitch are synthesized by reading a fundamental waveform (for example, a sinusoidal waveform) at different reading speed. Because the number of points sampled from the fundamental waveform decreases as the frequency increases, the characteristics of the synthesized tone signals deteriorate. Further, it is difficult to change the signal waveform with the passage of time.

Japanese Patent Postexam. Publication No. Sho-58-58679 has proposed a technique for synthesizing a tone signal by inputting a driving waveform signal into a closed loop formed by a serial connection of a filter and a delay circuit and repeatedly circulating the driving waveform signal in the closed loop. According to this technique, the amplitude, high-frequency content, high-frequency phase, etc. of the signal can be changed widely with the passage of time, so that musical tones more perfectly approaching the musical tones of natural musical instruments can be generated compared with the waveform read type tone signal synthesizer.

Such a tone signal synthesizer is also known from EP-A-0 248 527.

In recent electronic musical instruments, a technique for changing various characteristics by touch has been popularized. For example, the attack-decay-sustain-release waveform of a musical tone in a natural musical instrument can be simulated by controlling a sound volume envelope correspondingly to the touch. Further, the vibration of pitch caused by the touch can be simulated.

In natural musical instruments such as a piano, not only a sound volume changes in accordance with touch but the pitch and harmonic structure of a musical tone change just after key depression and then return to the designated pitch and the standard harmonic structure with the passage of time. With respect to the harmonic structure, the musical tone just after key depression contains many non-harmonic pitch components as well as

harmonics having pitches expressed by integers or simple fractional numbers with respect to the pitch of a fundamental tone. The non-harmonic pitch components decrease with the passage of time, so that a pure harmonic structure remains.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a tone signal synthesizer using a delayed feedback type tone synthesizing algorithm by which a musical tone can be controlled in accordance with touch.

Another object of the present invention is to provide a tone signal synthesizer by which various characteristics can be changed in accordance with touch to simulate the vibration of pitch and the generation of non-harmonic components caused by touch in a natural musical instrument.

These objects are achieved by the present invention as defined in the appended independent claims 1 and 10. Advantageous modifications of the present invention are defined by the dependent claims.

DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE PREFERRED EMBODIMENTS

To facilitate understanding of the present invention, first, a delayed feedback type tone signal synthesizer will be described.

Fig. 4 shows a tone generator circuit (tone signal synthesizer) like that disclosed in the above Japanese Patent Postexam. Publication No. Sho-58-58679. In the drawing, an address generator 21 generates an address signal according to a tone generation command, or the like, given from an CPU (not shown), or the like. A driving waveform memory 22 generates a driving waveform signal on the basis of the address signal and supplies the driving waveform signal into a closed loop constituted by a delay circuit 23 and a filter 24. The driving waveform signal circulates in the closed loop. The delay circuit 23 determines the time required for one circulation, that is, the pitch of a tone signal to be generated. The low-pass filter 24 gives such a decay characteristic in which the decay rate becomes high as the pitch becomes high. The tone signal can be picked up at a desired point in the closed loop.

Embodiments of the present invention will be described hereunder with reference to the drawings.

Fig. 1 is a block diagram showing the outline of an electronic keyboard instrument according to an embodiment of the present invention.

In the electronic keyboard instrument, the operation

thereof is generally controlled by a central processing unit (CPU) 10. A read-only memory (ROM) 11, a random access memory (RAM) 12, a keyboard circuit 13, a touch information detection circuit 14, an operation panel 16 and a tone generator circuit 17 are connected to the CPU 10 through a two-directional bus line BUS. A sound system 18 is connected to the tone generator circuit 17. A speaker 19 is connected to the sound system 18.

In Fig. 1, programs for controlling the CPU 10 and data necessary for generating various kinds of musical tones are stored in the ROM 11.

The RAM 12 is used as a temporary storage or register necessary for generating various kinds of musical tones.

The keyboard circuit 13 has a keyboard capable of touch detection. The keyboard circuit 13 detects the operation of a key on the keyboard and generates a key code representing the operated key, a key-on signal (KON) representing the state of key depression and a key-off signal (KOFF) representing the state of key release.

The touch information detection circuit 14 detects the key depression speed or key release speed of the key operated on the keyboard and generates initial touch information IT representing the key depression speed and release touch information RT representing the key release speed.

The operation panel 16 is provided for switching tone color and for setting other parameters necessary for the electronic musical instrument.

The tone generator circuit 17 synthesizes a musical tone signal on the basis of parameters given from the CPU 10.

The sound system 18 converts digital data outputted from the tone generator circuit 17 into analogue data for actuating the speaker 19, and, if necessary, amplifies the analogue data.

Fig. 2 shows the configuration of the tone generator circuit 17 depicted in Fig. 1. The tone generator circuit 17 changes the filter factor in accordance with touch. The circuit of Fig. 2 is the same as the circuit shown in Fig. 4 in that a driving waveform is read from a driving waveform memory 22 on the basis of an address signal generated by an address signal 21 and is supplied to a loop circuit. In the loop circuit, an all-pass filter 25 is connected in series to a filter 24. A filter factor generation circuit for giving a filter factor is connected to the all-pass filter 25.

The delay circuit 23, the low-pass filter 24 and the all-pass filter 25 constitute a feedback loop. The total delay amount of the delayed feedback loop corresponds to the pitch of the musical tone to be outputted. A conversion table 26, a comparator 27 and a pitch envelope generator 28 constitute a filter factor generation circuit.

The all-pass filter 25 is a filter having such a flat amplitude characteristic in which only the phase depends on the frequency in a predetermined use band. When a signal having a certain frequency circulates in the loop,

the phase difference between the original signal and the output signal depends on the delay characteristic of the loop, that is, depends on the frequency characteristic of the all-pass filter.

The operation of the circuit in Fig. 2 will be described hereunder. The address generator 21 receives information such as a memory read starting signal ST, a memory read starting point and a read data size DS from the CPU 10 shown in Fig. 1 and generates address information for reading the waveform signal from the driving waveform memory 22 on the basis of the information.

The driving waveform memory 22 outputs a driving waveform addressed by the address information and supplies the driving waveform into the loop circuit including the delay circuit 23, the filter 24 and the all-pass filter 25.

The delay circuit 23 is a circuit for delaying an input by a predetermined time. The delay circuit 23 may be constituted by a shift register, an RAM, or the like. DL represents the number of delay stages in the delay circuit 23 generated in a conversion circuit 30 on the basis of the key code KC representing pitch. In the case where the delay circuit 23 is constituted by a shift register, DL represents the number of stages in the shift register.

The filter 24 is a filter having the same decay as that of the filter 24 used in the tone generator in Fig. 4. To give strong decay for high pitch, the filter 24 generally constituted by a low-pass filter may be used in combination with a band-pass filter, or the like, for attaining a specific tone color. That is, the filter 24 is used for attaining both the frequency characteristic and the decay characteristic of the output tone. The cut-off frequency, the decay rate, or the like, as the filter parameter FPS, are given to the filter 24 by the CPU 10. Alternatively, in the case where an ordinary digital filter difficult to process as analogue data, such as FIR or IIR, is used, a set of filter factors are given as the filter parameter FPS.

The all-pass filter 25 is substantially different from the filter 24 in that the filter 25 has no decay and gives delay time depending on the frequency. The all-pass filter 25 is similar to the delay circuit in that it gives delay time, but the filter 25 is different from the delay circuit in that it can give frequency dependency to the delay time.

A filter factor generation circuit constituted by a conversion table 26, a comparator 27 and a pitch envelope generator 28 is provided for setting both a filter factor α for controlling frequency dependency and a filter factor n for designating delay time independent of the frequency.

To determine the filter factor α , the initial touch information IT supplied from the CPU 10 is compared with threshold information TO in the comparator 27. In the case of a piano, an output "1" is generated only when initial touch is not weaker than a predetermined threshold, in accordance with the fact that a change of pitch occurs when key touch is not weaker than a certain value. The threshold information TO may be given by a performer through the operation panel 16 or may be preset

in the ROM 11 corresponding to the tone color. When a change of pitch caused by touch is to be avoided, the threshold information TO may be set at the maximum on the operation panel 16 so that an output signal "0" is always generated because IT is always smaller than TO in the case where the threshold information TO is to be set on the operation panel 16. Alternatively, in the case where the threshold information TO is preset in the ROM 11, a switch may be provided separately so that the comparator can be disabled when the change of pitch is to be avoided.

The pitch envelope generator 28 outputs a pitch envelope curve corresponding to the initial touch IT and the key code KC. To meet with the phenomenon that the change of pitch becomes larger as the touch becomes stronger in the performance of a natural musical instrument, the pitch envelope curve is provided which depends on the initial touch IT. Because the pitch envelope must be changed rapidly in high pitch region in which decay is generally rapid, the pitch envelope curve is provided which depends on the key code KC, that is, key scaling is made.

A multiplier 29 following the pitch envelope generator 28 multiplies the output of the pitch envelope generator 28 by the output ("0" or "1") of the comparator 27 so that a signal for giving the change of pitch to the filter 25 can be supplied to the conversion table when the initial touch IT is not weaker than the threshold TO. That is, when the output of the comparator 27 is "0", the output of the multiplier 29 becomes "0" regardless of the output of the pitch envelope generator 28 so that there occurs no change of pitch. When the output of the comparator 27 is "1", the output of the pitch envelope generator 28 is directly used as the output of the multiplier 29 to be given to the conversion table 26.

The conversion table 26 is a table for converting the pitch envelope outputted from the pitch envelope generator 28 into the filter factor α of the all-pass filter 25 correspondingly to the real change of pitch. The conversion table 26 serves also as a table for converting the key code KC into the number n of delay stages as the other filter factor. The width of the pitch change is limited by the parameter n . The factors α and n given by the table 26 are fed to the filter 25.

Fig. 3 shows an example of the configuration of a general first order all-pass filter. Adders 34 and 35 are connected respectively to the input side and the output side of a delay circuit 33. The output is fed back to the input-side adder 34 in phase through an amplifier 32 having an amplification factor α . The input is fed forward to the output-side adder 35 in opposite phase through an amplifier having the amplification factor α . The frequency characteristic of the phase change can be changed variously by changing the amplification factor α of the amplifiers 31 and 32. When, for example, the amplification factor α is zero, the all-pass filter is simply a delay circuit to give delay time equal for all frequencies. In general, in the all-pass filter having this structure, the phase dif-

ference depending on the frequency is widened as the amplification factor α approaches 1.

The number n of delay stages corresponding to the key code KC as the number of stages in the delay circuit (for example, a shift register) 33 and the factor α variable with the passage of time and outputted from the pitch envelope generator 28 (Fig. 2) corresponding to the key code KC and the initial touch IT as the amplification factor α of the amplifiers 31 and 32 are supplied from the conversion table 26 of Fig. 2 to the all-pass filter of Fig. 3. As a result, a musical tone in which pitch changes corresponding to the factors α and n is synthesized in the tone generator circuit 17 of Fig. 2.

As described above, in an electronic musical instrument as shown in Fig. 1, having a tone generator circuit as shown in Fig. 2, using an all-pass filter as shown in Fig. 3, a musical tone can be changed finely corresponding to the touch in the performance manipulation. In the following, important parts thereof are described more in detail in conjunction with modifications thereof.

Means for detecting a touch signal is described now. Fig. 5 shows an example of a touch detection circuit in a keyboard instrument. A keyboard 40 has a large number of keys. A first contact and a second contact are provided in each of the keys. A group 41 of first contacts and a group 42 of second contacts are connected to a keyboard CPU 43. A counter 48 continuously counts a clock signal CL and supplies the count value to the CPU 43.

When the CPU 43 detects touch at the first contact of a certain key, the value of the running counter at the time of detection is stored. When the CPU 43 then detects touch at the second contact of the key, the value of the running counter at the time of detection is stored. The number of counts from the touch at the first contact to the touch at the second contact, that is, the time required from the touch at the first contact to the touch at the second contact, is detected by subtracting the value of the counter at the time of detection of the touch at the first contact from the value of the counter at the time of detection of the touch at the second contact. As the touch becomes stronger, the number of counts decreases. On the contrary, as the touch becomes weaker, the number of counts increases. The number of counts expressing the strength of the touch is converted into touch information by the CPU 43. The touch information is stored in a predetermined area of a dual port memory 46. These procedures are carried out according to a program stored in a program storage 44. The dual port memory 46 is also connected to the bus BUS. Data are exchanged between the CPU 10 of the musical instrument and the CPU 43 of the keyboard 40 through the memory.

Fig. 6 schematically shows an example of structure of the first and second contacts in the keyboard. Each key 51 is supported by a fulcrum 52 so as to be rotatable. When the key 51 is pressed down, a hammer 53 supported by a fulcrum 54 so as to be rotatable is pressed down. Two projections 55 and 56 are provided in the low-

er surface of the hammer 53. At least those projections 55 and 56 are formed of elastic substance. When urged down, the hammer 53 touches the first contact 57 to make it and then touches the second contact 58 to make it. Such touches at the first and second contacts 57 and 58 are detected by the CPU shown in Fig. 5.

Fig. 7A shows the external appearance of a wind instrument type electronic musical instrument. A large number of keys 62 for designating pitches are provided in a main portion of a wind instrument body 60. A mouthpiece 61 is connected to one end of the body 60. A desired tone signal is generated by holding the mouthpiece in the mouth, giving breath into the mouthpiece 61 and manipulating the keys 62.

Fig. 7B schematically shows a structure of the end portion of the wind instrument type electronic musical instrument 60 in the case where the mouthpiece 61 is detached. A pressure sensor 63 detects the pressure of breath of the performer. A cantilever 64 is formed so that the lever moves forth and back corresponding to the degree of closing of the performer's mouth to thereby give an output corresponding to the position of the lever. That is, the cantilever 64 detects the embouchure of the performer. The cantilever 64 being in contact with a lead of the wind instrument type manipulator detects the motion of the lead. The lead in the electronic musical instrument does not vibrate though the lead in a natural wind instrument vibrates. In short, the lead moves substantially merely corresponding to the state of the performer's mouth.

Fig. 7C shows a touch detection circuit adapted for the wind instrument type electronic musical instrument. The pressure sensor 63 and the cantilever 64 supply analogue signals corresponding to the pressure of breath and the embouchure to analog-to-digital converters 65 and 66, respectively. The analog-to-digital converters 65 and 66 convert input analogue signals into digital signals and supply the digital signals to a CPU 67. A timer 68 counts a clock signal CL and supplies the count value to the CPU 67. The CPU 67 detects the change of the pressure and the change of the embouchure in a period of a predetermined count value and forms a touch signal to be stored in a memory 69. The memory 69 is connected to the bus of the electronic musical instrument body to make data exchange between the memory 69 and the CPU of the electronic musical instrument body.

In the case of the wind instrument, the touch signal can be generated based on the breath pressure signal detected by the pressure sensor 63. Fig. 7D is a graph for explaining the detection of an initial touch signal IT.

The graph shows the case where the breath pressure rises gradually with the passage of time and then decreases slowly after reaching its maximum. The change of the breath pressure in a predetermined time T_w after exceeding a threshold level BR_0 is detected. The passage of time T_w is detected by counting the count value supplied from the timer 68. The breath pressure IT after the passage of time T_w is detected as initial touch.

The detection of such initial touch is made by interrupt processing at the time of detection of the breath pressure.

Figs. 8A and 8B show the detection of touch in the case of a percussion instrument.

Fig. 8A shows an initial touch detection circuit in a percussion instrument type electronic musical instrument. A vibration sensor 71 provided in a performance portion of the percussion instrument type electronic musical instrument detects vibration and supplies a detection signal to an analog-to-digital converter 72. The analog-to-digital converter 72 converts the signal into a digital signal and supplies the digital signal to a CPU 73. A timer 74 counts a clock signal and supplies a time signal to the CPU 73. The CPU 73 detects initial touch and makes an RAM 75 store initial touch information.

Fig. 8B is a graph for explaining the detection of initial touch. In the case of percussion instrument, the signal thus detected is a kind of alternating-current signal as shown in Fig. 8B. Because the detection signal is a kind of alternating-current signal, an envelope signal as shown by a broken line in Fig. 8B can be acquired by once subjecting the detection signal to a low-pass filter. A initial touch signal is detected by using the envelope signal in the same manner as described above with reference to Fig. 7D.

Although description is made upon the case of a percussion instrument, the aforementioned detection method can be also applied to a string instrument type electronic musical instrument in which vibration of a string is detected.

As described above, initial touch signals can be respectively detected from performance portions of electronic musical instruments having various performance styles. It is obvious to those skilled in the art that key code KC representing pitch and other tone forming parameters can be detected correspondingly to the form of the musical instrument.

In the following, main constituent members of the tone generator circuit shown in Fig. 2 are described. Fig. 9 shows an example of the configuration of the address generator 21. A full adder 81, a delay circuit 82 and an AND circuit group 83 are connected in series to constitute a loop circuit. A comparator 84 compares an input-A with an input-B and supplies "1" to the full adder 81 when the input-A is larger than the input-B. The input-A of the comparator 84 is connected to a latch circuit 85. The output of the loop circuit is fed out as an address signal through an adder 88. The output of a latch circuit 86 is applied to the adder 88. The latch circuits 85 and 86 latch the data size DS and the starting pointer SP, respectively.

When a starting pulse SP is given, the data in the loop circuit is reset by the AND circuit group 83. Thereafter, if the value in the loop is smaller than DS, the signal is increased by "1" in the full adder 81. When the value in the loop reaches DS, the output of the comparator 84 becomes zero so that the increment operation of the loop stops. The value in the loop is added to the starting point-

er SP representing an address starting point by the adder 88 to thereby generate an address signal AD.

Fig. 10A is a diagram for explaining the function of the all-pass filter shown in Fig. 3. The input, the output, the amplification factor and the delay constant of the delay circuit are represented by X, Y, k and Z^{-1} , respectively.

When the respective values are represented as described above, the output Y can be expressed by the following equation.

$$Y = kYZ^{-1} + XZ^{-1} - kX$$

$$Y(1 - kZ^{-1}) = X(Z^{-1} - k)$$

$$Y/X = (Z^{-1} - k)/(1 - kZ^{-1})$$

Fig. 10B shows a circuit equivalent to the circuit of Fig. 10A and expressed by another circuit form.

The delay characteristic of a transfer function

$$H(Z) = (Z^{-1} - k)/(1 - kZ^{-1})$$

is expressed by the equation:

$$\tau(\omega X) = T(1 - k^2)/(1 - 2k\cos\omega T + k^2)$$

in which ω represents the angular velocity, and $\tau(\omega X)$ represents the delay time for the angular velocity ωX .

Fig. 11 is a graph in which the ratio of the delay time to the sampling period T is plotted with respect to the change of ωT . This relationship is the relationship between the phase angle and the frequency. When this relationship is rearranged to the relationship between the frequency and the delay amount, a curve as shown by a broken line is acquired.

It is obvious from Fig. 11 that the phase angle changes widely correspondingly to the frequency when the amplification factor $\alpha(k$ in the aforementioned equation) of the amplifiers 31 and 32 in the circuit of Fig. 3 is changed.

Fig. 12 is a graph showing an example of the change with the passage of time, of the amplification factor α given to the all-pass filter 25. The amplification factor α rises to a value near to 1 in response to the key on KON corresponding to key depression on the keyboard (or the like) and then decreases in the form of an exponential function. When α is near 1, many non-harmonic components are generated as is obvious from Fig. 11. The amplification factor α must be smaller than 1, because the all-pass filter becomes divergent for a direct current when α is 1.

Fig. 13 is a graph showing the change with the passage of time, of the number n of delay stages given to the all-pass filter 25. The number n of delay stages decreases by a predetermined amount from a reference delay value N corresponding to the key on KON and then increases gradually to approach the original reference delay value N.

In general, in a piano or the like, pitch rises at the time of string touch and then is gradually converged to a predetermined value. In order to realize this phenomenon by using the number of delay stages, it is necessary

to reduce the number of delay stages at the time of key on KON and then converge the pitch to a predetermined value gradually. Fig. 14 shows the configuration of a memory type envelope generator 28.

A full adder 91, a delay circuit 92 and an AND circuit group 93 constitute a loop circuit which is the same as in Fig. 9. Latch circuits 96 and 97 latch key code KC information and initial touch IT information and supply them to a table 94 for deducing an accumulation value from the key code KC and a table 95 for deducing a factor from the initial touch IT, respectively. These latch circuits 96 and 97 are enabled by receiving a starting pulse ST. The starting pulse ST also serves to reset a counter 98. The counter 98 receives "carry out" from the full adder 91. A value corresponding to KC is accumulated by the loop to thereby generate a carry signal from the full adder 91 to thereby increase the value of the counter 98. When the value of the counter 98 reaches its maximum, the counting operation of the counter stops to keep the maximum value. As the key code KC becomes larger, a larger value is set to the table 94 for deducing an accumulation value from the key code KC. Accordingly, the envelope advances more rapidly as the pitch becomes higher. The count value of the counter 98 is used as an address of a memory 99, so that a signal having a waveform as shown in Fig. 14 is read from the memory 99. In a multiplier 100, the signal read from the memory 99 is multiplied by a factor supplied from the table 95, so that a pitch envelope IT' corresponding to the initial touch IT is generated. This pitch envelope IT' has such a characteristic as shown in the right side of Fig. 14, in which the pitch changes more widely as the input becomes larger. When the pitch envelope IT' is "0", the total pitch becomes equal to the pitch of the key code KC.

In the following, examples of configuration of the conversion table 26 shown in Fig. 2 are described.

Fig. 15 shows an example of the configuration of the conversion table using the envelope generator in Fig. 14. With respect to the amplification factor α , the pitch envelope IT' supplied can be used directly. With respect to the number n of delay stages, a procedure of subtraction from the fundamental delay length N is required. Because it is necessary to scale the range of the change of delay length corresponding to the key code KC, a factor corresponding to the key code is generated by using a table 102 for deducing a factor from the key code KC. This factor is multiplied by the pitch envelope in a multiplier 103, is inverted in an amplifier 104, and then is added to (or subtracted from) the fundamental delay length N. Thus, delay length n is generated.

Fig. 16 shows an example of the configuration of a calculation type envelope generator. A full adder 106, a delay circuit 107 and an AND circuit group 108 constitute a loop circuit. The output of a table 109 for deducing an accumulation value from the key code is applied to the full adder 106. The key code KC is supplied to the table 109 through a latch circuit 111. On the other hand, the initial touch IT is supplied to a table 113 for deducing a

factor, through a latch circuit 112. The output of the table 113 is given to a down counter 114. The starting pulse ST is supplied to the latch circuits 111 and 112 and the down counter 114. When the starting pulse ST is "1", the down counter 114 loads the value of IT. Thereafter, the down counter 114 makes such a down counting operation whenever a carry rises from the full adder 106. A decreasing function having linear characteristic in a range of from a certain value to zero is acquired by: initially setting a value corresponding to the initial touch IT to the down counter; and decreasing the value of the down counter one by one in the timing corresponding to the key code KC. Here, the down counter is defined as a counter in which the counting operation thereof stops to keep the output of the counter zero when the value of the counter reaches zero.

In the pitch envelope in Fig. 16, an output decreasing linearly is generated. In order to change this to the form of U as shown in the waveform in the right side of Fig. 14, conversion tables as shown in Fig. 17 can be used. The conversion tables 116 and 117 receive the output of the counter 114 shown in Fig. 16 and generate a factor a having U-shaped characteristic and a factor n having reversed-U-shaped characteristic.

In the case of Fig. 16, tables having a time axis reverse to that of the tables in Fig. 12 are provided because the down counter is used. The reason why theories in Figs. 16 and 17 are reversed with respect to the time axis is as follows. It is considered that the output values of these tables may become zero correspondingly to the output of the comparator. In this case, the aforementioned tables are required for outputting standard values. The table 117 for the number of delay stages is arranged so that some curves can be selected from the key code KC.

Fig. 18 shows an example of the configuration of the delay circuit 23 of Fig. 2. A plurality of delay circuits 121, 122, ..., 126 are connected in series, so that the respective outputs thereof are supplied to a selector circuit 128. The selector circuit 128 supplies an output for a predetermined number of delay stages correspondingly to the selective input. Thus, there is formed a delay circuit variable in the number of delay stages.

The circuit of Fig. 2 or a circuit equivalent to the circuit of Fig. 2 can be formed by using constituent members as described above.

In order to realize the non-harmonic just after the key on, it is important that the phase of the all-pass filter 25 is changed so as to depend on the frequency. Although the loop circuit of Fig. 2 contains the delay circuit 23, the low-pass filter 24 and the all-pass filter 25, the low-pass filter 24 is not always necessary.

Fig. 19 shows an example of a loop circuit constituted by a delay circuit 23 and an all-pass filter 25. The change after the key on can be realized by such a circuit.

As described above, a musical tone closely resembling that of a natural musical instrument can be controlled by providing an all-pass filter in a delayed feedback

loop and, in particular, controlling non-harmonic components on the basis of touch information.

It is to be understood that the invention is not limited to the aforementioned embodiments and that changes thereof may be made suitably within the scope of the invention as defined by the appended claims.

Although, for example, the aforementioned embodiments have shown the case where the pitch is modulated by changing the factor of the all-pass filter corresponding to the touch, the change of frequency in a larger range can be obtained by changing the delay time of the delay circuit corresponding to the touch.

The objects of the invention can be attained not only by software using CPU but by hardware.

Although the above description has been made upon the case where a linear all-pass filter is used, the invention can be applied to the case where a multi-dimensional all-pass filter is used.

Although description has been made on limited number of embodiments, the present invention is not limited thereto. It will be apparent for those skilled in the art that various changes, substitutions, alterations, improvements and combinations are possible within the scope of the appended claims.

Claims

1. A tone signal synthesizer comprising:

a loop circuit (23,24,25) for circulating a tone signal;
means (21,22) for applying a driving waveform to said loop circuit;
a delay circuit (23) connected within said loop circuit, for giving delay time corresponding to pitch to the circulating tone signal;
touch signal generation means (14) for generating a touch signal;
a variable all-pass filter (25) connected within said loop circuit and being capable of changing the phase of the tone signal corresponding to the frequency thereof, based on said touch signal;
a factor generation means (26,27,28,29) for generating an amplification factor α which changes with the passage of time correspondingly to a touch signal; and
means (26) for applying said amplification factor α to said all-pass filter.

2. A tone signal synthesizer according to Claim 1, in which said factor generation means includes means for generating a pitch envelope which increases pitch by a quantity corresponding to the touch signal simultaneously with the starting of performance manipulation and then decreases the pitch in the form of an exponential function.

3. A tone signal synthesizer according to Claim 2, in which said factor generation means controls the decay of the pitch envelope correspondingly to pitch.

4. A tone signal synthesizer according to Claim 1, further comprising:

said touch signal generation means forming the touch signal on the basis of performance information given by a performance manipulator in correspondence with a performance; and means for supplying said touch signal to said factor generation means.

5. A tone signal synthesizer according to Claim 4, in which: said performance manipulator has a large number of keys, and said touch signal forming means includes means for detecting the speed of key depression.

6. A tone signal synthesizer according to Claim 4, in which: said performance manipulator includes a mouthpiece applied to a mouth and for giving out breath there through, and said touch signal forming means includes a pressure sensor for detecting the pressure of the breath.

7. A tone signal synthesizer according to Claim 4, in which: said performance manipulator includes a vibrating member, and said touch signal forming means includes means for forming an envelope of vibration generated on the vibration member and for detecting a change of the envelope.

8. A tone signal synthesizer according to Claim 1, in which said all-pass filter includes: a delay element for delaying an input signal; a first amplifier for amplifying the input signal with said amplification factor α ; a first adder for adding the amplified input signal to the output of said delay element in reversed phase; a second amplifier for amplifying the output of said first adder with the amplification factor α ; and a second adder for adding the output of said second amplifier to the input signal in phase at the input side of said delay element, the delay time of said delay element and the amplification factor α of the first and second amplifiers being controlled on the basis of an externally applied control signal.

9. A tone signal synthesizer according to Claim 8, further including means for receiving a signal representing pitch and a signal representing touch and for supplying to said all-pass filter a signal for controlling the amplification factor α and the delay time.

10. A tone signal synthesizer for an electronic musical instrument comprising:

a loop means (23,24,25) for circulating a tone signal;

a applying means (22) for applying a driving signal to the loop means;

a delay means (23) connected within the loop means, for delaying the circulating tone signal for a delay time corresponding to a tone pitch of a tone signal to be generated;

an all-pass filter means (25) connected within the loop means, for changing the phase of the circulating tone signal corresponding to the frequency thereof according to an all-pass filter characteristic;

a touch signal generation means (14) for generating a touch signal representing a degree of a performance;

a control means (26,27,28,29) for controlling the all-pass filter characteristic in response to the touch signal.

11. A tone signal synthesizer for an electronic musical instrument according to claim 10, wherein the all-pass filter means changes the phase of the circulating tone signal during a lapse of time in response to the touch signal.

12. A tone signal synthesizer for an electronic musical instrument according to claim 10, wherein the touch signal generation means having a performance manipulation means for providing a performance and a touch signal forming means for forming a touch signal on the basis of a degree of the performance.

Patentansprüche

1. Tonsignalsynthesizer, der folgendes aufweist:

eine Schleifenschaltung (23, 24, 25) zur Zirkulation eines Tonsignals;

Mittel (21, 22) zum Einspeisen einer Treiberwellenform in die Schleifenschaltung;

eine in die Schleifenschaltung geschaltete Verzögerungsschaltung (23) zur Festlegung einer der Tonhöhe des zirkulierenden Tonsignals entsprechenden Verzögerungszeit;

Anspielstärkesignalerzeugungsmittel (14) zur Erzeugung eines Anspielstärkesignals;

ein in die Schleifenschaltung geschaltetes variables Allpaßfilter (25), das geeignet ist, die Phase des Tonsignals entsprechend dessen Frequenz auf der Grundlage des Anspielstärkesignals zu ändern;

Faktorerzeugungsmittel (26, 27, 28, 29) zur Erzeugung eines Verstärkungsfaktors α , der sich im Laufe der Zeit entsprechend einem

Anspielstärkesignal ändert; und Mittel (26), um den Verstärkungsfaktor dem Allpaßfilter zuzuführen.

2. Tonsignalsynthesizer nach Anspruch 1, bei dem die Faktorerzeugungsmittel Mittel zur Erzeugung einer Tonhöhenhüllkurve aufweisen, durch die die Tonhöhe um einen dem Anspielstärkesignal entsprechenden Wert gleichzeitig mit Beginn der Spielbetätigung gesteigert und dann nach einer exponentiellen Funktion verringert wird.

3. Tonsignalsynthesizer nach Anspruch 2, bei dem die Faktorerzeugungsmittel das Abfallen der Tonhöhenhüllkurve entsprechend der Tonhöhe steuern.

4. Tonsignalsynthesizer nach Anspruch 1, bei dem die Anspielstärkesignalerzeugungsmittel das Anspielstärkesignal auf der Grundlage von Spielinformation bilden, die durch eine Spieleinrichtung entsprechend einem Spiel geliefert wird, und bei dem ferner Mittel vorgesehen sind, um das Anspielstärkesignal den Faktorerzeugungsmitteln zuzuleiten.

5. Tonsignalsynthesizer nach Anspruch 4, bei dem die Spieleinrichtung eine große Zahl von Tasten aufweist, und die Anspielstärkesignalbildungsmittel Mittel zur Feststellung der Geschwindigkeit des Tastenanschlags aufweisen.

6. Tonsignalsynthesizer nach Anspruch 4, bei dem die Spieleinrichtung ein Mundstück aufweist, durch das mit dem Mund Luft geblasen wird und die Anspielstärkesignalbildungsmittel einen Drucksensor zum Feststellen des Blasdrucks aufweisen.

7. Tonsignalsynthesizer nach Anspruch 4, bei dem die Spieleinrichtung ein Vibrationsteil aufweist, und die Anspielstärkesignalbildungsmittel Mittel aufweisen, um eine Hüllkurve für die am Vibrationsteil erzeugte Vibration zu bilden und eine Änderung der Hüllkurve festzustellen.

8. Tonsignalsynthesizer nach Anspruch 1, bei dem das Allpaßfilter folgendes aufweist: ein Verzögerungselement zur Verzögerung eines Eingangssignals; einen ersten Verstärker zum Verstärken des Eingangssignals mit dem Verstärkungsfaktor α ; einen ersten Addierer zum Addieren des verstärkten Eingangssignals zu dem Ausgangssignal des Verzögerungselements in Gegenphase; einen zweiten Verstärker zur Verstärkung des Ausgangssignals des ersten Addierers mit dem Verstärkungsfaktor α ; und einen zweiten Addierer, um das Ausgangssignal des zweiten Verstärkers zu dem Eingangssignal in Phase an der Eingangsseite des Verzögerungselements zu addieren, wobei die Verzögerungszeit des Verzögerungselements und der Verstärkungsfaktor

α des ersten und zweiten Verstärkers auf der Grundlage eines von außen angelegten Steuersignals gesteuert werden.

9. Tonsignalsynthesizer nach Anspruch 8, der ferner Mittel aufweist, um ein Signal, das die Tonhöhe repräsentiert, und ein Signal, das die Anspielstärke repräsentiert, zu empfangen und dem Allpaßfilter ein Signal zur Steuerung des Verstärkungsfaktors α und der Verzögerungszeit zuzuleiten.

10. Tonsignalsynthesizer für ein elektronisches Musikinstrument, der folgendes aufweist:

Schleifenmittel (23, 24, 25) für die Zirkulation eines Tonsignals;
Einspeisemittel (22) zum Einspeisen eines Treibersignals in die Schleifenmittel;
in die Schleifenmittel geschaltete Verzögerungsmittel (23), um das zirkulierende Tonsignal um eine Verzögerungszeit zu verzögern, die der Tonhöhe eines zu erzeugenden Tonsignals entspricht;
in die Schleifenmittel geschaltete Allpaßfiltermittel (25) zur Änderung der Phase des zirkulierenden Tonsignals entsprechend seiner Frequenz gemäß einer Allpaßfiltercharakteristik;
Anspielstärkesignalerzeugungsmittel (14) zur Erzeugung eines Anspielstärkesignals, das den Grad einer Spielbetätigung repräsentiert;
Steuermittel (26, 27, 28, 29) zur Steuerung der Allpaßfiltercharakteristik im Ansprechen auf das Anspielstärkesignal.

11. Tonsignalsynthesizer für ein elektronisches Musikinstrument nach Anspruch 10, bei dem die Allpaßfiltermittel die Phase des zirkulierenden Tonsignals im Laufe der Zeit im Ansprechen auf das Anspielstärkesignal ändern.

12. Tonsignalsynthesizer für ein elektronisches Musikinstrument nach Anspruch 10, bei dem die Anspielstärkesignalerzeugungsmittel Spielbetätigungsmittel zum Durchführen eines Spiels sowie Anspielstärkesignalsbildungsmittel zur Bildung eines Anspielstärkesignals auf der Grundlage der Stärke des Spiels aufweist.

Revendications

1. Synthétiseur de signal sonore comprenant :

un circuit en boucle (23, 24, 25) pour la circulation d'un signal sonore ;
des dispositifs (21, 22) pour appliquer un signal de commande audit circuit en boucle ;
un circuit de retard (23) raccordé dans ledit cir-

cuit en boucle destiné à donner un temps de retard correspondant pour accorder ledit signal sonore circulant ;

un dispositif de génération de signal tactile (14) pour générer un signal tactile ;

un filtre passe-bande variable (25) raccordé dans ledit circuit en boucle et étant capable de modifier la phase du signal sonore correspondant à la fréquence de celui-ci en fonction dudit signal tactile ;

des dispositifs de génération de facteur (26, 27, 28, 29) pour générer un facteur d'amplification α qui varie avec le passage du temps correspondant à un signal tactile ; et

un dispositif (26) pour appliquer ledit facteur d'amplification a audit filtre passe-bande.

2. Synthétiseur de signal sonore conforme à la revendication 1, dans lequel ledit dispositif de génération du facteur comprend un dispositif pour générer une enveloppe d'accord qui augmente l'accord d'une grandeur correspondant au signal tactile simultanément avec le début de la manipulation de contrôle et réduit ensuite l'accord sous la forme d'une fonction exponentielle.

3. Synthétiseur de signal sonore conforme à la revendication 2, dans lequel ledit dispositif de génération de facteur commande la décroissance de l'enveloppe d'accord de manière correspondante à l'accord.

4. Synthétiseur de signal sonore conforme à la revendication 1, comprenant en plus :

ledit dispositif de génération de signal tactile formant le signal tactile sur la base des informations de contrôle délivrées par un manipulateur de contrôle en correspondance avec un contrôle ; et

un dispositif pour fournir ledit signal tactile audit dispositif de génération de facteur.

5. Synthétiseur de signal sonore conforme à la revendication 4, dans lequel :

ledit manipulateur de contrôle est muni d'un grand nombre de touches et ledit dispositif de formation du signal tactile comporte un dispositif pour détecter la vitesse d'enfoncement des touches.

6. Synthétiseur de signal sonore conforme à la revendication 4, dans lequel :

ledit manipulateur de contrôle comporte un embout buccal appliqué sur une bouche et destiné à laisser sortir le souffle au travers de lui, et ledit dispositif de formation du signal tactile comporte un capteur de pression pour détecter la pression du souffle.

7. Synthétiseur de signal sonore conforme à la revendication 4, dans lequel :

ledit manipulateur de contrôle comporte un élément vibrant, et ledit dispositif de formation de signal tactile comporte un dispositif pour former une enveloppe de vibrations générée sur l'élément vibrant et pour détecter une modification de l'enveloppe.

8. Synthétiseur de signal sonore conforme à la revendication 1, dans lequel ledit filtre passe-bande comporte : un élément de retard pour retarder un signal d'entrée ; un premier amplificateur pour amplifier le signal d'entrée avec ledit facteur d'amplification α ; un premier additionneur pour additionner le signal d'entrée amplifié à la sortie dudit élément de retard en inversion de phase ; un deuxième amplificateur pour amplifier la sortie dudit premier additionneur avec le facteur d'amplification α ; et un deuxième additionneur pour additionner la sortie dudit deuxième amplificateur au signal d'entrée en phase du côté de l'entrée dudit élément de retard, le temps de retard dudit élément de retard et le facteur d'amplification α du premier et du deuxième amplificateurs étant commandés sur la base d'un signal de commande appliqué depuis l'extérieur.

9. Synthétiseur de signal sonore conforme à la revendication 8, comportant en plus un dispositif pour recevoir un accord représentant un signal et une impulsion représentant un signal et pour amener audit filtre passe-bande un signal destiné à commander le facteur d'amplification α et le temps de retard.

10. Synthétiseur de signal sonore pour un instrument de musique électronique comprenant :

un dispositif en boucle (23, 24, 25) pour la circulation d'un signal sonore ;
un dispositif d'application (22) destiné à appliquer un signal de commande au dispositif en boucle ;
un dispositif de retard (23) raccordé au sein du dispositif en boucle pour retarder le signal sonore circulant d'un temps de retard correspondant à un accord sonore d'un signal sonore devant être généré ;
un dispositif filtre passe-bande (25) raccordé au sein du dispositif en boucle pour modifier la phase du signal sonore circulant correspondant à la fréquence de celui-ci conformément aux caractéristiques d'un filtre passe-bande ;
un dispositif de génération de signal tactile (14) pour générer un signal tactile représentant un niveau de contrôle ;
un dispositif de commande (26, 27, 28, 29) pour commander les caractéristiques du filtre

passe-bande en réaction au signal tactile.

11. Synthétiseur de signal sonore pour un instrument de musique électronique conforme à la revendication 10, dans lequel le dispositif filtre passe-bande modifie la phase du signal sonore circulant pendant un intervalle de temps en réaction au signal tactile.
12. Synthétiseur de signal sonore pour un instrument de musique électronique conforme à la revendication 10, dans lequel le dispositif de génération de signal tactile comporte un dispositif de manipulation de contrôle pour fournir un contrôle et un dispositif de formation de signal tactile pour former un signal tactile basé sur un niveau de contrôle.
