Titre : CONNECTEUR A DOUBLE ORIENTATION A CONTACTS EXTERNES
Title: DUAL ORIENTATION CONNECTOR WITH EXTERNAL CONTACTS

A dual orientation connector having a connector tab with first and second major opposing sides and a plurality of electrical contacts carried by the connector tab. The plurality of contacts includes a first set of external contacts formed at the first major side and a second set of external contacts formed at the second major side. The first plurality of contacts are symmetrically spaced with the second plurality of contacts and the connector tab is shaped to have 180 degree symmetry so that it can be inserted and operatively coupled to a corresponding receptacle connector in either of two insertion orientations.

DUAL ORIENTATION CONNECTOR WITH EXTERNAL CONTACTS

CROSS-REFERENCES TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

[0002] The present invention relates generally to input/output electrical connectors such as audio connectors and data connectors.

[0003] Standard audio connectors or plugs are available in three sizes according to the outside diameter of the plug: a 6.35 mm (1/4") plug, a 3.5 mm (1/8") miniature plug and a 2.5 mm (3/32") subminiature plug. The plugs include multiple conductive regions that extend along the length of the connectors in distinct portions of the plug such as the tip, sleeve and one or more middle portions between the tip and sleeve resulting in the connectors often being referred to as TRS (tip, ring and sleeve) connectors.

[0004] Figs. 1A and 1B illustrate examples of audio plugs 10 and 20 having three and four conductive portions, respectively. As shown in FIG. 1A, plug 10 includes a conductive tip 12, a conductive sleeve 16 and a conductive ring 14 electrically isolated from the tip 12 and the sleeve 16 by insulating rings 17 and 18. The three conductive portions 12, 14, 16 are for left and right audio channels and a ground connection. Plug 20, shown in FIG. 1B, includes four conductive portions: a conductive tip 22, a conductive sleeve 26 and two conductive rings 24, 25 and is thus sometime referred to as a TRRS (tip, ring, ring, sleeve) connector. The four conductive portions are electrically isolated by insulating rings 27, 28 and 29 and are typically used for left and right audio, microphone and ground signals. As evident from Figs. 1A and 1B, each of audio plugs 10 and 20 are orientation agnostic. That is, the conductive portions completely encircle the connector forming 360 degree contacts such that there is no distinct top, bottom or side to the plug portion of the connectors.
When plugs 10 and 20 are 3.5 mm conductive sleeve 16, 26 and conductive rings 14, 24, 25 is 3.5 mm and the insertion length of the connector is 14 mm. For 2.5 mm subminiature connectors, the outer diameter of the conductive sleeve is 2.5 mm and the insertion length of the connector is 11 mm long. Such TRS and TRRS connectors are used in many commercially available MP3 players and smartphones as well as other electronic devices. Electronic devices such as MP3 players and smartphones are continuously being designed to be thinner and smaller and/or to include video displays with screens that are pushed out as close to the outer edge of the devices as possible. The diameter and length of current 3.5 mm and even 2.5 mm audio connectors are limiting factors in making such devices smaller and thinner and in allowing the displays to be larger for a given form factor.

Many standard data connectors are also only available in sizes that are limiting factors in making portable electronic devices smaller. Additionally, and in contrast to the TRS connectors discussed above, many standard data connectors require that they be mated with a corresponding connector in a single, specific orientation. Such connectors can be referred to as polarized connectors. As an example of a polarized connector, Figs. 2A and 2B depict a micro-USB connector 30, the smallest of the currently available USB connectors. Connector 30 includes a body 32 and a metallic shell 34 that extends from body 32 and can be inserted into a corresponding receptacle connector. As shown in Figs. 2A, 2B, shell 34 has angled corners 35 formed at one of its bottom plates. Similarly, the receptacle connector (not shown) with which connector 30 mates has an insertion opening with matching angled features that prevents shell 34 from being inserted into the receptacle connector the wrong way. That is, it can only be inserted one way - in an orientation where the angled portions of shell 34 align with the matching angled portions in the receptacle connector. It is sometimes difficult for the user to determine when a polarized connector, such as connector 30 is oriented in the correct insertion position.

Connector 30 also includes an interior cavity 38 within shell 34 along with contacts 36 formed within the cavity. Cavity 38 is prone to collecting and trapping debris within the cavity which may sometimes interfere with the signal connections to contacts 36. Also, and in addition to the orientation issue, even when connector 30 is properly aligned, the insertion and extraction of the connector is not precise, and may have an inconsistent feel. Further, even when the connector is fully inserted, it may have an undesirable degree of wobble that may result in either a faulty connection or breakage.
[0008] Many other commonly used data mini USB connectors, FireWire connectors, as well as many of the proprietary connectors used with common portable media electronics, suffer from some or all of these deficiencies or from similar deficiencies.

5 BRIEF SUMMARY OF THE INVENTION

[0009] Various embodiments of the invention pertain to plug connectors and receptacle connectors that improve upon some or all of the above described deficiencies. Other embodiments of the invention pertain to methods of manufacturing such plug and/or receptacle connectors as well as electronic devices that include such connectors.

10 Embodiments of the invention are not limited to any particular type of connector and may be used for numerous applications. Some embodiments, however, are particularly well suited for use as audio connectors and some embodiments are particularly well suited for data connectors.

[0010] In view of the shortcomings in currently available audio and data connectors as described above, some embodiments of the present invention relate to improved audio and/or data plug connectors that have a reduced plug length and thickness, an intuitive insertion orientation and a smooth, consistent feel when inserted and extracted from its corresponding receptacle connector. Additionally, some embodiments of plug connectors according to the present invention have external contacts instead of internal contacts and do not include a cavity that is prone to collecting and trapping debris.

[0011] One particular embodiment of the invention pertains to a dual orientation plug connector having external contacts carried by a connector tab. The connector tab can include first and second opposing sides with a first set of contacts formed on the first side and a second set of contacts formed on the second side. The first set of contacts can be symmetrically spaced with the second set of contacts and the connector tab can have a 180 degree symmetrical shape so that it can be inserted and operatively coupled to a corresponding receptacle connector in either of two insertion orientations. In some embodiments the plug connector further includes one or more ground contacts formed on side surfaces of the connector tab that extend between the first and second surfaces, and in some additional embodiments the connector tab includes a cap or ground ring that covers the tip of the connector and extends from the tip towards the body along at least a portion of each of the
side surfaces. In some further embodiment:

feature adapted to engage with a retention feature on a corresponding receptacle connector.

[0012] In another embodiment, the invention pertains to a dual orientation electrical connector comprising a body and a connector tab extending longitudinally away from the body that includes first and second opposing surfaces. A plurality of electrical contacts are carried by the connector tab including a first set of external contacts formed at the first surface and a second set of external contacts formed at the second surface. The connector tab is shaped to have 180 degree symmetry and the first set of contacts is symmetrically spaced with the second set of contacts allowing the connector to be inserted into a corresponding receptacle connector in either of two orientations. In some instances, the connector tab can further include a side peripheral surface that extends between the first and second opposing surfaces and at least one ground contact formed on the side peripheral surface. Additionally, in some embodiments the connector still further includes a metal ground ring that generally defines a shape of the connector tab and includes openings on both the first and second surfaces in which the first and second sets of contacts are respectively formed and surrounded by a dielectric. Still in some other embodiments, the body includes a flexible member or is made from a flexible material that allows the connector to bend with respect to an insertion axis in which the connector is mated with a receptacle connector.

[0013] In still another embodiment, the invention pertains to a dual orientation electrical plug connector having a body, a cable attached to the body, and an unpolarized connector tab extending longitudinally away from the body. The connector tab may have a generally rectangular cross section defined by first and second major opposing surfaces and first and second opposing side surfaces extending between the first and second major surfaces. A plurality of electrical wiping contacts can be carried by the connector tab including a first set of external contacts formed at the first major surface and extending parallel to each other along a length of the connector, and a second set of external contacts formed at the second major surface and extending parallel to each other along the length of the connector. The connector may also include first and second retention features formed on the first and second opposing side surfaces, respectively, that are adapted to engage with retention features on a corresponding receptacle connector to secure the connector together during a mating event. In some embodiments, the first retention feature may also function as a first ground contact and the second retention feature may also function as a second ground contact. The first set of contacts can be symmetrically spaced with the second set of contacts, and the first ground
contact can be symmetrically spaced with 11
has 180 degree symmetry and can be inserted and operatively coupled to the corresponding receptacle connector in either of two positions.

[0014] Other embodiments of the invention pertain to electrical receptacle connectors. In one embodiment, the receptacle connector can include a housing that defines an interior cavity extending in a direction of the depth of the housing and a plurality of electrical contacts positioned within the cavity. The cavity can have a 180 degree symmetrical shape so that a corresponding plug connector can be inserted into the cavity in either of two insertion orientations. Additionally, the plurality of contacts may include a first set of contacts positioned at a first interior surface of the cavity and a second set of contacts positioned at a second interior surface of the cavity spaced apart from the first interior surface in an opposing relationship. The first and second sets of contacts can further be mirror images of each other. In some embodiments, the receptacle connector can also include at least one retention feature adapted to engage with a retention feature on a corresponding plug connector. In still other embodiments, the receptacle connector can include first and second retention features positioned on opposing side surfaces the cavity adapted to engage with first and second retention features on a corresponding plug connector.

[0015] In another embodiment, the invention pertains to an electrical plug connector that includes a conductive cap or ground ring to isolate the connector’s contacts from interference. The connector can further include a body and a connector tab that is attached to and extends longitudinally away from the body. The conductive cap can cover a tip of the connector and extend from the tip towards the body along at least a portion of the connector tab’s side surfaces. A plurality of external contacts can be carried by the connector tab at a location at least partially surrounded by the conductive cap. In some embodiments the plurality of external contacts can include contacts formed at both first and second major opposing surfaces of the connector tab, and in some embodiments the contacts formed at the first and second surfaces are arranged on each surface in matching patterns. Additionally, in some embodiments the conductive cap can be a metal cap and in some embodiments the connector can further include first and second ground contacts formed on the sides of the conductive cap. In different embodiments the conductive cap may be a U-shaped frame or may generally define a shape of the connector tab except for the one or more contact regions of the connector tab in which the plurality of contacts are formed.
[0016] In still another embodiment, a met
body and a tab that is adapted to be inserted into a corresponding receptacle connector is
disclosed. The method includes forming the connector tab to have first and second major
opposing surfaces, third and fourth opposing side surfaces extending between the first and
second surfaces and a 180 degree symmetrical design such that a plane bisecting a width of
the connector tab at an angle perpendicular to the first and second major surfaces divides the
tab into left and right portions that have substantially the same outer shape and a horizontal
plane bisecting a height of the connector tab at an angle perpendicular to the third and fourth
side surfaces divides the tab into upper and lower portions that have substantially the same
outer shape; forming a first contact region at the first major surface of the connector tab and a
second contact region at a second major surface of the connector tab opposite the first major
surface, the first and second contact regions being substantially the same size and shape and
including an equal number of contacts, wherein contacts in the first contact region are
arranged in a first pattern according to a first spacing and contacts in the second contact are
also arranged in the first pattern according to the first spacing; and attaching a cable having a
plurality of insulated wires to the body so that each individual wire in the plurality of
insulated wires is electrically connected to a contact in either the first or second contact
regions.

[0017] To better understand the nature and advantages of the present invention, reference
should be made to the following description and the accompanying figures. It is to be
understood, however, that each of the figures is provided for the purpose of illustration only
and is not intended as a definition of the limits of the scope of the present invention. Also, as
a general rule, and unless it is evident to the contrary from the description, where elements in
different figures use identical reference numbers, the elements are generally either identical
or at least similar in function or purpose.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018] Figs. 1A and 1B show perspective views of previously known TRS audio plug
connectors;

DETAILED DESCRIP

[0088] The present invention will now be described in detail with reference to certain embodiments thereof as illustrated in the accompanying drawings. In the following description, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without some or all of these specific details. In other instances, well known details have not been described in detail in order not to unnecessarily obscure the present invention.

[0089] In order to better appreciate and understand the present invention, reference is first made to Figs. 3A-3C, which are simplified top, side and front views, respectively, of a plug connector 40 according to one embodiment of the present invention. Connector 40 includes a body 42 and a tab portion 44. A cable 43 is attached to body 42 and tab portion 44 extends away from body 42 in a direction parallel to the length of the connector 40. Tab 44 is sized to be inserted into a corresponding receptacle connector during a mating event and includes a first contact region 46a formed on a first major surface 44a and a second contact region 46b (not shown in Figs. 3A-3C) formed at a second major surface 44b opposite surface 44a. A plurality of contacts (not shown in Figs. 3A-3C) can be formed in each of contact regions 46a and 46b such that, when tab 44 is inserted into a corresponding receptacle connector, contacts in regions 46a, 46b are electrically coupled to corresponding contacts in the receptacle connector. In some embodiments, the plurality of contacts are self-cleaning wiping contacts that, after initially coming into contact with a receptacle connector contact during a mating event, slide further past the receptacle connector contact with a wiping motion before reaching a final, desired contact position.

[0090] Tab 44 also includes first and second opposing side surfaces 44c, 44d that extend between the first and second major surfaces 44a, 44b. While tab 44 is shown in Figs. 3A-3C as having a substantially rectangular and substantially flat shape, in some embodiments of the invention first and second major surfaces 44a, 44b may have matching convex or concave curvatures to them or may have a matching recessed region centrally located between the sides of tab 44. Contact regions 46a and 46b may be formed in the recessed regions and the recessed regions may, for example, extend from the distal tip of tab 44 all the way to base 42 or may extend along only a portion of the length of tab 44 (e.g., between ½ to ¾ of the length of the tab) ending at a point short of base 42. Side surfaces 44c and 44d may also have matching convex or concave curvatures.
[0091] Generally, the shape and curvature of surfaces 44a and 44b, in accordance with the dual orientation design of connector 40 as described below. Additionally, while Figs. 3A-3C show surfaces 44c, 44d as having a width significantly less that that of surfaces 44a, 44b (e.g., less than or equal to one half width of surfaces 44a, 44b), in some embodiments of the invention side surfaces 44c, 44d have a width that is relatively close to or even equal with or wider than that of surfaces 44a, 44b.

[0092] Figs. 4A-4C are simplified front plan views of embodiments of connector 40 in which body 42 and/or tab 44 have different cross-sectional shapes. For example, in Fig. 4A, major surfaces 44a and 44b are slightly convex, while in Figs. 4B and 4C, side surfaces 44c and 44d are rounded. Further, Fig. 4C depicts an example of a connector having recessed regions 45a and 45b formed at major surfaces 44a and 44b, respectfully, of tab 44. The recessed regions extend from the distal tip of tab 44 along a portion of the length of tab 44 and are centrally located between side surfaces 44c and 44d. A person of skill in the art will understand that Figs. 3C and 4A-4C are but examples of suitable cross-sectional shapes for body 42 and tab 44 and that many other cross-sectional shapes may be employed for each of body 42 and tab 44 in various embodiments of the invention.

[0093] In some embodiments, one or more ground contacts can be formed on the side surfaces. For example, Figs. 3A and 3B show a ground contact 47a formed on first side surface 44c and a ground contact 47b formed on second side surface 44d opposite ground contact 47a. As another example, one or more ground contacts may be formed on end surface 44e at the distal tip of connector 40 in addition to, or instead of ground contacts 47a, 47b. In some embodiments, each of the one or more ground contacts can be formed on or form part of an outer portion of its respective side surface. In other embodiments, the one or more ground contacts can be formed within and/or as part of a pocket, indentation, notch or similar recessed region formed on each of the side surfaces 44c, 44d that operatively engage with a retention mechanism in a corresponding receptacle connector as described in detail below.

[0094] Body 42 is generally the portion of connector 40 that a user will hold onto when inserting or removing connector 40 from a corresponding receptacle connector. Body 42 can be made out of a variety of materials and in some embodiments is made from a dielectric material, such as a thermoplastic polymer formed in an injection molding process. While not
shown in Figs. 3A or 3B, a portion of cable
be enclosed by body 42. Also, electrical contact to the contacts in each of regions 46a, 46b
can be made to individual wires in cable 43 within body 42. In one embodiment, cable 43
includes a plurality of individual insulated wires, one for each contact within regions 46a and
46b, that are soldered to bonding pads on a printed circuit board (PCB) housed within body
42. Each bonding pad on the PCB is electrically coupled to a corresponding individual
contact within one of contact regions 46a or 46b.

[0095] Tab 44 may also be made from a variety of materials including metal, dielectric or a
combination thereof. In some embodiments, tab 44 includes a frame made primarily or
exclusively from a metal, such as stainless steel, and contact regions 46a and 46b are formed
within the frame. In some other embodiments, tab 44 includes a frame made primarily or
exclusively from a dielectric material, such as a ceramic or an elastomeric material. For
example, tab 44 may be a ceramic base that has contacts printed directly on its surfaces.

[0096] In embodiment illustrated in Figs. 3A and 3B, body 42 has a rectangular cross
section that generally matches in shape but is slightly larger than the cross section of tab 42.
As discussed with respect to Figs. 4A-4C, body 42 can be of a variety of shapes and sizes,
however. For example, body 42 may have a rectangular cross section with rounded or angled
edges (referred to herein as a "generally rectangular" cross section), a circular cross section,
an oval cross section as well as many other suitable shapes. In some embodiments, both the
body 42 and tab 44 of connector 40 have the same cross-sectional shape and have the same
width and height (thickness). As one example, body 42 and tab 44 may combine to form a
substantially flat, uniform connector where the body and tab seem as one. In still other
embodiments, the cross section of body 42 has a different shape than the cross section of tab
44. As one example, body 42 may have curved upper and lower and/or curved side surfaces
while tab 44 is substantially flat.

[0097] Each of contact regions 46a, 46b can be centered between opposing side surfaces
44c, 44d. Individual contacts in contact regions 46a and 46b can be external contacts
positioned at an outer surface of tab 44 so that some embodiments of connector 40 do not
include contacts positioned within an internal cavity in which particles and debris may
collect. Each of contact regions 46a and 46b can include one or more contacts that can be
made from copper, nickel, brass, a metal alloy or any other appropriate conductive material.
In some embodiments contacts can be print similar to those used to print contacts on printed circuit boards.

[0098] Contact regions 46a and 46b may include any number of contacts, from one to twenty or more arranged in a variety of different patterns. Figs. 5A-5H provide different examples of contact arrangements within a contact region 46 according to different embodiments of the invention. As shown in Fig. 5A, contact region 46 may include two contacts 51(1) and 51(2) that are centered and symmetrically positioned within the contact region. Similarly, Fig. 5B depicts a contact region 46 having three contacts 52(1)..52(3) centered and symmetrically positioned within the contact region, and Fig. 5C depicts a contact region 46 having four such contacts 53(1)..53(4).

[0099] While each of Figs. 5A-5C include a single row of contacts within region 46, some embodiments of the invention may include two, three or more rows of contacts. As examples, contact region 46 shown in Fig. 5D includes two rows of four contacts 54(1)..54(4) and 54(5)..54(8) with each row being centered between the sides of the contact region and symmetrically spaced with respect to a center line traversing the length of the contact region; Fig. 5E shows a contact region 46 having a first row of three contacts 55(1)..51(3) and a second row of four contacts 55(4)..55(7) positioned within the contact region; and Fig. 5F depicts a contact region 46 having three rows of three contacts for a total of nine contacts 56(1)..56(9).

[0100] While each row of individual contacts in the contact regions shown in Figs. 5A-5F center the contacts in the row between the sides of the contact region and symmetrically space the contacts with respect to a center line traversing the length of the contact region, in some embodiments of the invention the contacts need not be centered in this manner. As an example, Fig. 5G depicts a contact region 46a having two contacts 57(1)..57(2) that are not centered within the contact region. To provide the 180 degree symmetry employed by some embodiments of the invention, a connector that includes the contact region 46a shown in Fig. 5G on one major surface, includes a contact region 46b as shown in Fig. 5H on the opposing major surface that matches contact region 46a. In Fig. 5H, contact region 46b and contacts 57(3)-57(4) are shown in dashed lines to represent the position of the contacts when looking from contact region 46a through the connector to contact region 46b.

[0101] Each of the contact regions 46 shown in Figs. 5A-5G is representative of both regions 46a and 46b according to particular embodiments of the invention. That is, according
to one embodiment of the invention, a plug
and 46b each of which includes two contacts as shown in region 46 in Fig. 5A. In another
embodiment, a plug connector 40 includes contact regions 46a and 46b each of which
includes three contacts as shown in Fig. 5B. Still other embodiments of the invention
include: a connector 40 having contact regions 46a and 46b as shown in region 46 in Fig.
5C; a connector 40 having contact regions 46a and 46b as shown in region 46 in Fig. 5D; a
connector 40 having contact regions 46a and 46b as shown in region 46 in Fig. 5E; a
connector 40 having contact regions 46a and 46b as shown in region 46 in Fig. 5F; and a
connector 40 having contact regions 46a and 46b as shown in region 46 in Fig. 5G.

[0102] Contacts within regions 46a, 46b may include contacts designated for a wide variety
of signals including power contacts, ground contacts, analog contacts and digital contacts
among others. In some embodiments, one or more ground contacts are formed in regions 46a
and/or 46b while in other embodiments, ground contacts are only located at the tip 44e and/or
on the side surfaces 44c, 44d of connector 40 in order to save space within contact regions
46a and 46b for power and signal contacts. Embodiments that employ ground contacts at one
or more positions along the peripheral side and/or tip surfaces of connector 40 instead of
within contact regions 46a and 46b may enable the overall footprint of connector tab 44 to be
smaller than a similar connector that includes ground contacts in contact regions 46a or 46b.

[0103] Power contacts within regions 46a, 46b may carry signals of any voltage and, as an
example, may carry signals between 2-30 volts. In some embodiments, multiple power
contacts are included in regions 46a, 46b to carry power signals of different voltages levels
that can be used for different purposes. For example, one or more contacts for delivering low
current power at 3.3 volts that can be used to power accessory devices connected to connector
40 can be included in regions 46a, 46b as well as one or more contacts for delivering high
current power at 5 volts for charging portable media devices coupled to connector 40.

[0104] Examples of analog contacts that may be included in contact regions 46a, 46b
include contacts for separate left and right channels for both audio out and audio in signals as
well as contacts for video signals, such as RGB video signals, YPbPr component video
signals and others. Similarly, many different types of digital signals can be carried by
contacts in regions 46a, 46b including data signals such as, USB signals (including USB 1.0,
2.0 and/or 3.0), FireWire (also referred to as IEEE 1394) signals, SATA signals and/or any
other type of data signal. Digital signals within contact regions 46a, 46b may also include
signals for digital video such as DVI signal:
as other digital signals that perform functions that enable the detection and identification of
devices or accessories to connector 40.

[0105] In some embodiments, dielectric material is filled in between individual contacts in
contact regions 46a, 46b so that the dielectric material and contacts form a completely flush
outer surface of tab 44 that provides a smooth, consistent feel across the surfaces of tab 44.
Additionally, to improve robustness and reliability, connector 40 can be fully sealed and
includes no moving parts.

[0106] Connector 40 can have a 180 degree symmetrical, double orientation design which
enables the connector to be inserted into a corresponding receptacle connector in both a first
orientation where surface 44a is facing up or a second orientation where surface 44a is
rotated 180 degrees and facing down. To allow for the orientation agnostic feature of
connector 40, tab 44 is not polarized. That is, tab 44 does not include a physical key that is
configured to mate with a matching key in a corresponding receptacle connector designed to
ensure that mating between the two connectors occurs only in a single orientation. Instead, if
tab 44 is divided into top and bottom halves along a horizontal plane that bisects the center of
tab 44 along its width, the physical shape of the upper half of tab 44 is substantially the same
as the physical shape of the lower half. Similarly, if tab 44 is divided into left and right
halves along a vertical plane that bisects the center of tab along its length, the physical shape
of the left half of tab 44 is substantially the same as the shape of the right half. Additionally,
contacts can be positioned within contact regions 46a and 46b so that individual contacts in
region 46a are arranged symmetric with the individual contacts in region 46b located on the
opposite side of tab 44, and ground contacts formed at the tip or on the sides of connector tab
44 can also be arranged in a symmetric manner.

[0107] To better understand and appreciate the 180 degree symmetrical design of some
embodiments of the invention, reference is made to Figs. 6A and 6B which are simplified
views of a first side 44a and an opposing second side 44b, respectively, of a plug connector
50 according to a specific embodiment of the invention that includes four individual contacts
formed within each of contact regions 46a and 46b. For example, as shown in Fig. 6A,
contact region 46a may include four evenly spaced contacts 53(1)…53(4) formed within the
region. With respect to a center plane 59 that is perpendicular to and passes through the
middle of connector 50 along its length, contacts 53(1) and 53(2) are in a mirrored
relationship with contacts 53(3) and 53(4).

53(2) is the same as the spacing from center line 59 to contact 53(3). Also, the spacing from center line 59 to contact 53(1) is the same as the spacing from centerline 59 to contact 53(4). Each of the pairs of contacts 53(1), 53(2) and 53(3), 53(4) are also spaced equally from the sides 44c and 44d of the connector with respect to each other and are spaced equally along the length of tab 44 between end surface 44e and body 42.

[0108] Similarly, in Fig. 6B contact region 44b includes the same number of contacts as region 44a that are also spaced according to the same spacing in region 44a. Thus, contact region 44b includes four contacts 53(5)…53(8) spaced within region 46b according to the same layout and spacing as contacts 53(1)…53(4) within regions 46a. Because the layout and spacing of contacts in regions 46a and 46b are identical, absent some sort of indicia or mark on one of surfaces 44a or 44b, the surfaces and contact layout on each of surfaces 44a, 44b looks the same. When connector 50 is inserted into a corresponding receptacle connector, the contacts in regions 46a, 46b will make proper electrical contact with contacts in the receptacle connector in either of two different orientations (referred to herein as “up” or “down” for convenience but it is to be appreciated that these are relative terms intended to connote a 180 degree change in the orientation of the connector only).

[0109] To further illustrate, reference is now made to Figs. 7A and 7B, which schematically show a cross-sectional view of plug connector 50 having four contacts in each of regions 46a, 46b as depicted in Figs. 6A and 6B inserted into a matching receptacle connector 60. Receptacle connector 60 includes a cavity 64 into which the tab of the plug connector can be inserted. Four contacts 61(1)…61(4) extend from one interior surface of the receptacle connector into cavity 64 and four contacts 61(5)…61(8) extend from the opposing interior surface into cavity 64 in an oppositional and mirrored relationship to contacts 61(1)…61(4).

[0110] Fig. 7A depicts that when the connector 50 is inserted into cavity 65 in an “up” position, contact 53(1) of the plug connector aligns with contact 61(1) of the receptacle connector, contact 53(2) aligns with contact 61(2), contact 53(3) aligns with contact 61(3) and contact 53(4) aligns with contact 61(4). Fig. 7A also shows that, on the opposing surface, contact 53(5) aligns with contact 61(5), contact 53(6) aligns with contact 61(6), contact 53(7) aligns with contact 61(7) and contact 53(8) aligns with contact 61(8). When the plug connector is inserted into receptacle connector 60 in a “down” position, as shown in Fig.
7B, each contact in the plug connector still |
connector. The contacts align differently, however, as follows: contact 53(5) of the plug |
connector aligns with contact 61(1) of the receptacle connector, contact 53(6) aligns with |
contact 61(2), contact 53(7) aligns with contact 61(3) and contact 53(8) aligns with contact |
61(4), while on the opposing surface, contact 53(1) aligns with contact 61(5), contact 53(2) |
aligns with contact 61(6), contact 53(3) aligns with contact 61(7) and contact 53(4) aligns |
with contact 61(8). Additionally, when plug connector 50 includes side ground contacts 53a, |
53b, each side contact aligns with a corresponding side ground contact 61a, 61b from |
receptacle connector 60 in either of the two possible insertion orientations as shown in Figs. |
7A and 7B.

[0111] Thus, whether connector 50 is inserted into receptacle connector 60 in either the |
“up” or “down” position, proper electrical contact is made between the contacts in the plug |
connector and the receptacle connector. Embodiments of the invention further pertain to a |
receptacle connector that includes circuitry that switches the functionality of its pins based on |
the orientation of the plug connector. In some embodiments, a sensing circuit in the |
receptacle connector or the electronic device in which the receptacle connector is housed, can |
detect the orientation of the plug connector and set software and/or hardware switches to |
switch internal connections to the contacts in the receptacle connector and properly match the |
receptacle connector’s contacts to the plug connector’s contacts as appropriate. In some |
embodiments the orientation of the plug connector can be detected based on a physical |
orientation key (different from a polarization key in that an orientation key does not prevent |
the plug connector from being inserted into the receptacle connector in multiple orientations) |
that, depending on the orientation of the plug connector, engages or does not engage with a |
corresponding orientation contact in the receptacle connector. Circuitry connected to the |
orientation contact can then determine which of the two possible orientations the plug |
connector was inserted into the receptacle connector.

[0112] As an example, reference is now made to Figs. 8A-8C, which show simplified top, |
bottom and side plan views of a plug connector 70 according to another embodiment of the |
present invention along with Figs. 9A and 9B, which are simplified schematic views of plug |
connector 70 inserted within a receptacle connector 80. Connector 70 includes contact |
regions 46a and 46b formed on opposing major surfaces of the connector that may contain |
any reasonable number of contacts. For example, in the particular embodiment shown in Fig. |
9A, connector 70 is an audio plug connector and each of contact regions 46a and 46b include
two contacts: a microphone contact and rig contact and a ground contact in region 46b. When connector 70 is mated with receptacle connector 80, an orientation key 72 on the plug connector engages (or doesn’t engage) with a corresponding orientation contact 86 within receptacle connector 80.

5 [0113] Circuitry operatively coupled to the receptacle connector can set software and/or hardware switches to properly match the receptacle connector’s contacts to the contacts of plug connector 70. For example, a software switch can be used to switch the connector jack’s contacts for left and right audio depending on the insertion orientation while a hardware switch can be used to switch the connector jacks microphone and ground contacts to match the contacts of connector 70. In other embodiments, both switches can be implemented in software or both switches can be implemented in hardware. A comparison of Fig. 9A to 9B illustrates the switching of the receptacle contacts depending on whether or not orientation contact 86 is engaged (Fig. 9B) or not engaged (Fig. 9A), where for ease of illustration, the labels of the switched contacts are underlined and depicted in a larger font.

15 [0114] As another example, connector 70 can be a six contact audio plug connector with each of contact regions 46a, 46b including three contacts as shown in Figs. 9C-9D: a microphone contact, a first dedicated ground contact and a right audio contact are within region 46a; while a left audio contact, a second dedicated ground contact and a second dedicated microphone contact are located within region 46b. The first and second ground contacts and first and second microphone contacts align with ground and microphone contacts of the corresponding connector jack 80 regardless of the insertion orientation of connector 70. Thus, this embodiment can be carried out with a single switch, that can be implemented in software or hardware to switch the connector jack’s contacts for left and right audio depending on the insertion orientation which can be detected by orientation contact 86 within the receptacle connector.

[0115] As shown in Figs. 8A-8C, connector 70 can also include retention features 74a, 74b on opposing side surfaces of the connector. Retention features can operate to secure connector 70 in a corresponding receptacle connector as discussed below with respect to Figs. 12A and 12B. Notably, in the embodiment shown in Figs. 8A-8C, retention feature 74b and orientation key 72 combine to form a single extended cutout on the side 44d of connector 70. In other embodiments, the retention feature(s) and orientation key can be completely separated from each other and even be included on separate surfaces. For example, in one
embodiment orientation key 72 can be located.
retention features can be located on one or both of side surfaces 44c and 44d.

[0116] In other embodiments, the plug connector does not include an orientation key and
the orientation of the connector can instead be detected by circuitry associated with the
corresponding receptacle connector based on signals received over the contacts. As one
example, various accessories such as headsets for cellular phones include a microphone and
allow a user to perform basic functions such as setting earphone volume and answering and
ending calls with the push of a button on the accessory. A single wire, serial control chip can
be used to communicate with the host electronic device and implement this functionality.

The chip is connected to the microphone contact (e.g., contact 112b shown in Fig. 14A) and,
when the plug connector is inserted into the receptacle jack, can talk to appropriate circuitry
in the jack connector or host device. Upon an insertion event, the host device sends an
Acknowledgment signal to the serial control chip over the contact in the receptacle connector
designated for the microphone and waits for a Response signal. If a Response signal is
received, the contacts are aligned properly and audio and other signals can be transferred
between the connectors. If no response is received, the host device flips the signals to
correspond to the second possible orientation (i.e., flips the signals 180 degrees) and repeats
the Acknowledgement/Response signal routine.

[0117] In the four contact embodiment of a plug connector 70 shown in Fig. 9E, left and
right audio contacts are always in physically reversible positions while each of the other two
contacts is designated as a microphone contact. In this embodiment, a physical orientation
key in the plug connector, such as key 72, can be detected by an orientation contact or other
appropriate mechanism in the receptacle connector to determine the orientation of the plug,
and a hardware or software switch can set the receptacle connector contacts as appropriate for
left and right audio to correspond to the plug connector contacts. In the embodiment of plug
connector 70 shown in Fig. 9F, a contact 75 is connected to ground through, for example, a
ground ring 102 (described with respect to Figs. 10A-10B). When the connector is first
plugged into a receptacle connector, circuitry associated with the receptacle connector or the
electronic device in which the connector is housed detects the position of the grounded
contact and switches the receptacle contacts to an appropriate orientation.

[0118] To facilitate the dual orientation feature of certain embodiments of the invention,
contacts within contact regions 46a, 46b can be arranged such that similarly purposed
contacts are located on opposite sides of the
For example, referring back to Fig. 7A, contact 53(1) is in a cater cornered arrangement with
contact 53(5) while contact 53(2) is in a cater cornered relationship with contact 53(6).
Similarly purposed contacts are contacts that are designated to carry similar signals.

Examples of similarly purposed contact pairs may include, first and second power contacts,
left and right audio out contacts, first and second ground contacts, a pair of data differential
contacts, and/or first and second digital contacts. Because of the symmetrical relationship
between the contacts, such a cater cornered relationship ensures that for each pair of similarly
purposed contacts in a cater cornered relationship, one of the similarly purposed contacts will
be electrically connected to a contact in the receptacle connector that is either dedicated to the
particular contact or can be readily switched to the particular contact. As an example, where
contacts 53(1) and 53(5) are similarly purposed contacts that are dedicated to left and right
audio out signals, respectively, when plug connector 50 is inserted into receptacle connector
60, one of the audio out contacts will be in electrical contact with receptacle contact 61(1)
and the other of the audio out contacts will be in electrical contact with receptacle contact
61(5) regardless of whether the plug connector is mated with the receptacle connector in an
“up” or “down” insertion orientation. Thus, both the receptacle contacts 61(1) and 61(5) can
be audio contacts ensuring that they will be electrically coupled to an audio contact in the
plug connector regardless of its insertion orientation.

[0119] While Figs. 7A-7B depict a particular embodiment of the invention with an even
number of contacts in each of contact regions 46a and 46b, some embodiments of the
invention may include an odd number of contacts in each of regions 46a, 46b. In such
embodiments, one of the contacts on each side of the plug connector is a central contact that
is centered around bisecting line 59a and thus aligns with a centrally located receptacle
contact in both the “up” and “down” positions. The central contacts are not in a cater
cornered arrangement but are in a symmetrical arrangement and can be similarly purposed
contacts according to some embodiments of the invention.

[0120] Figs. 10A and 10B illustrate this aspect of certain embodiments of the invention and
depict a plug connector 70 having three contacts 52(1)..52(3) and 52(4)..52(6) formed on the
upper and lower surfaces of tab 44 of the plug connector, respectively. When the connector
tab is inserted into a corresponding receptacle connector 80 in an “up” position, contacts
52(1)..52(3) align with contacts 81(1)..81(3) of the receptacle connector, respectively, and
contacts 52(4)..52(6) align with contacts 81(4)..81(6), respectively. When the connector tab
is inserted into receptacle connector 80 in a contacts 81(1).81(3) of the receptacle connector, respectively, and contacts 52(1)..52(3) align with contacts 81(4).81(6), respectively. In both orientations, plug connector contacts 52(2) and 52(5) align with one of the central receptacle contacts 81(2) or 81(5).

[0121] Plug connector 40 can be designed to be inserted into a matching receptacle connector, such as receptacle connector 80, along an insertion axis. In some embodiments of the invention, at least a portion of the plug connector is made from a flexible material so that the connector can readily bend off-axis. As an example, Fig. 11A shows a simplified side cross-sectional view of a connector 90 similar to connector 40 that is intended to be inserted into a receptacle connector along an insertion axis 95. Tab 44 of connector 90 includes a flexible carrier member 92 that extends the length of tab 44 along with contacts (not shown) formed on each of the opposing surfaces 44a, 44b of connector 90 that can flex with carrier member 92. As an example, the contacts can be part of a flex circuit that is bonded to flexible carrier member 92. Flexible carrier 92 and the flexible contacts allow tab 44 to be bent along a direction 94 into a deformed shape as shown in Fig. 11B when the connector is mated with a receptacle connector 97 (i.e., positioned with an insertion cavity 98 of the receptacle connector) and subject to strain by being pulled in a direction 96 that intersects insertion axis 95. As soon as the strain is relieved, tab 44 returns to its normal shape shown in Fig. 11A. In this manner, when connector 90 is pulled out of its receptacle connector by pulling at least partially sideways (e.g., along direction 96 as opposed to pulling along axis 95) on either body 42 or the cable (not shown) attached to body 42, plug connector 90 can bend and pull out of the receptacle connector rather than binding within it or eventually breaking.

[0122] In one particular embodiment, flexible carrier 92 is a sheet of superelastic material, such as nitinol (an alloy of nickel and titanium present in roughly equal amounts) and the flexible contacts are part of a flex circuit adhered to the superelastic sheet. Nitinol alloys exhibit elasticity some 10-30 times that of ordinary metal which enables it to flex under very high strain without breaking. The flex circuit may include, for example, metal contacts screen printed on a thin polyimide or PEEK (polyether ether ketone) layer. The flex circuit may be made from two separate pieces each of which is directly adhered to one side of the nitinol sheet or may be a single piece wrapped around the perimeter of the nitinol sheet or made into a sleeve that fits over the nitinol sheet.
Embodiments of the invention that limited to the use of any particular superelastic material and can instead use any material that deforms reversibly to very high strains and returns to its original shape when the load is removed without requiring a change of temperature to regain its original shape. Some embodiments of the invention may use flexible materials for carrier 92 that are not superelastic. For example, carrier 92 or tab 44 itself can be made from an elastomer or polyurethane in some embodiments.

When connector plug 90 is engaged with a corresponding receptacle connector and extracted at an angle to the insertion axis, more force is typically applied to the base of the connector than at its tip. To address this discrepancy, in some embodiments the flexibility of carrier 92 varies along the length of the carrier so that, for example, it is more flexible near the base portion or proximal end of the connector where it meets body 42 and less flexible near the distal end of the connector. Flexibility can be varied in this manner by, among other techniques, varying the materials along the length of the connector, varying the thickness of the flexible carrier along its length or varying the shape of the flexible carrier along its length or any combination of these approaches. For example, in one embodiment carrier 92 may include a superelastic sheet near its base and a polyurethane sheet near its distal end. The superelastic and polyurethane sheets may overlap and be adhered together in an area between the proximal and distal ends. In one particular embodiment, carrier 92 comprises two sheets of polyurethane near the distal end of tab 44 and a single sheet of nitinol near the base of tab 44 where the tab joins body 42. At a point approximately one third of the length of the connector from the distal end, the nitinol sheet is sandwiched between the two polyurethane sheets for a portion of the length.

Reference is now made to Figs. 12A and 12B, which are simplified top and side views of a plug connector 100 according to another embodiment of the invention. Plug connector 100 includes many of the same features as plug connector 40 but further includes a cap 102, and first and second retention features 104a and 104b, respectively, near a distal tip of the connector. Cap 102 can be made from a metal or other conductive material and can extend from the distal tip of connector 100 along the side of the connector towards body 42 either fully or partially surrounding contacts formed in contact regions 46a and 46b in the X and Y directions. Cap 102 can be grounded in order to minimize interference that may otherwise occur on the contacts of connector 100. In one embodiment, cap 102 may be a u-shaped frame having a thickness that is equivalent to the thickness (T) of connector 100. In
another embodiment, cap 102 covers the en
46b and thus defines the shape of tab 44. Cap 102 is sometimes referred to herein as a
ground ring and those two terms are intended to be used interchangeably. Cap 102 can be
formed in a variety of ways and in one embodiment can be die cast from a metal, such as
stainless steel, that can be slid over and attached to the end of connector tab 44 thus partially
or fully surrounding contact regions 46a and 46b at the tip and sides of the connector.

[0126] Figs. 13A and 13B show two different embodiments of cap 102. In Fig. 13A, cap
102 is a u-shaped frame that can be attached to or slid over the end of the connector. Cap 102
includes side portions 102a, 102b that may have varying lengths in different embodiments.

In some embodiments sides 102a, 102b extend past contact regions 46a, 46b all the way to
the body 42 of the connector. In other embodiments the sides may extend past contact
regions 46a, 46b but not all the way to body 42 (as shown in Fig. 12A); may extend exactly
to the end of contact regions 46a, 46b or may be relatively short and extend only partially
along the length of the contact regions. Contact regions 46a, 46b lie between the opposing
sides 102a, 102b. In still other embodiments, cap or ground ring 102 defines the exterior
shape of tab 44 completely surrounding the contact regions 46 at the outer surfaces of the
connector as shown in Fig. 13B.

[0127] Referring back to Figs. 12A and 12B, retention features 104a, 104b are formed on
the opposing sides of connector 100 and are part of a retention system that includes one or
more features on the plug connector that are adapted to engage with one or more features on
the corresponding receptacle connector to secure the connectors together when the plug
connector is inserted into the receptacle connector. In the illustrated embodiment, retention
features 104a, 104b are semi-circular indentations in the side surfaces of tab 44 that extend
from surface 44a to surface 44b. The retention features may be widely varied and may
include angled indentations or notches, pockets that are formed only at the side surfaces and
do not extend to either of the surfaces 44a, 44b upon which contact regions 46a, 46b are
formed, or other recessed regions. The retention features are adapted to engage with a
retention mechanism on the receptacle connector that can be similarly widely varied. The
retention mechanism(s) may be, for example, one or more springs that includes a tip or
surface that fits within indentations 104a, 104b, one or more spring loaded detents, or similar
latching mechanisms. The retention system, including retention features 104a, 104b and the
.corresponding retention mechanism on the receptacle connector, can be designed to provide
specific insertion and extraction forces such that the retention force required to insert the plug
connector into the receptacle connector is h
the plug connector from the receptacle connector.

[0128] While retention features 104a, 104b are shown in Figs. 12A and 12B as having a
female mating characteristic and the retention mechanism was described above as having a
male characteristic that is moved into the retention features 104a, 104b, in other embodiments
these roles may differ. For example, in one embodiment, retention features 104a, 104b may
be spring loaded projections that engage with a female retention mechanism on the receptacle
connector. In still other embodiments, one of features 104a, 104b may be male-oriented
while the other of features 104a, 104b is female-oriented. In other embodiments, other
retention mechanisms can be used such as mechanical or magnetic latches or orthogonal
insertion mechanisms. Additionally, while retention features 104a and 104b are shown in
Figs. 12A and 12B as being formed in metal cap 102, in embodiments of the invention that
do not include a metal cap or ground ring, the retention features can be formed in whatever
structure or material makes up tab 44.

[0129] Retention features 104a, 104b can also be located at a variety of positions along
connector 100 including along the side surfaces of tab 44 and/or top and bottom surfaces of
tab 44. In some embodiments, retention features 104a, 104b can be located on a front surface
42a of body 42 and adapted to engage with a retention mechanism located on a front exterior
surface of the receptacle connector. In the embodiment illustrated in Figs. 12A and 12B,
retention features 104a, 104b are positioned within the last third of the length of tab 44. The
inventors have determined that positioning the retention features and corresponding latching
mechanism in the receptacle connector near the end of the plug connector helps to better
secure the connector sideways when it is in an engaged position within the receptacle
connector.

[0130] The description of various embodiments of the invention set forth above with
respect to Figs. 3A-13B describes a number of different features, aspects and variations of
different embodiments of the invention. To gain a further understanding of the invention,
numerous additional embodiments and examples of the invention including both audio
connector and data connector embodiments are discussed below that include some or all of
the features already mentioned as well as additional features. The various embodiments
discussed below include many features in common with embodiments already discussed and
with each other. As a matter of convenience such common features are often, but not always,
referred to with the same reference number. to a connector having a specific number of contacts generally refers to the number of contacts on the opposing major surfaces of the connector and does not include any ground or other contacts formed on the tip and/or sides of the connector.

[0131] Fig. 14A is a simplified perspective view of a four contact plug connector 110 according to an embodiment of the invention while Figs. 14B-14D are simplified top, side and bottom plan views, respectively, of connector 110. As shown connector 110 includes a tab 44 that extends from body 42. Tab 44 has a front major surface 44a upon which two contacts 112a and 112b are positioned and a back major surface 44b upon which two contacts 112c and 112d are located.

[0132] The contacts can be made from a copper, nickel, brass, a metal alloy or any other appropriate conductive material. Spacing is consistent between each pair of contacts 112a, 112b and 112c, 112d providing 180 degree symmetry so that plug connector 110 can be inserted into a corresponding receptacle connector in either of two orientations. In one particular embodiment, connector 110 is an audio plug connector and contact 112a is a left audio contact, contact 112b is a microphone contact, contact 112c is a right audio contact and contact 112d is a second, redundant microphone contact. Embodiments of the invention are not limited to any particular contact arrangement, however, and can be designated for other signals. In another four contact plug connector embodiment, connector 110 is a data connector and each of contacts 112a-112d can be designated for data signals. For example, contacts 112a and 112b can be designated for a first pair of differential data signals (e.g., data transmit) while contacts 112c and 112d can be designated for a second pair of differential data signals (e.g., data receive). In other embodiments, contacts 112a-112d can be designated for a wide variety of other signal types.

[0133] Metal ground ring 102 defines the shape of tab 44 and surrounds the contacts 112a-112d along an outer periphery of the tab. Two semi-circular notches 104a and 104b, are formed in ground ring 102 and located on opposing sides 44c and 44d of the tab near its distal end. In operation, tab 44 is inserted into a receptacle connector (e.g., shown in Figs. 28A-28C) until notches 104a and 104b operatively engage with a retention mechanism, such as a cantilevered spring or detent.

[0134] In the engaged position, each of contacts 112a-112d is in electrical contact with a corresponding contact in the receptacle connector. Tab 44 has a 180 degree symmetrical,
double orientation design which enables the
with either surface 44a or 44b on top. Additionally, the two audio contacts 112a and 112c are
located on opposite sides of the connector in a cater cornered arrangement. Thus,
5 microphone contact 112d is located directly opposite audio contact 112a and microphone
contact 112b is located directly opposite audio contact 112c. In this manner, an audio contact
is always on the right side of the connector and a microphone contact is always on the left
side of the connector (as oriented from the connector base to the distal end). A sensing circuit
in the receptacle connector or the electronic device in which the receptacle connector is
housed, can detect the direction that the contacts 112a-112d are set and switch internal
connections to the contacts in the connector jack appropriately as described above.

[0135] As shown in Figs. 14A-14D, contacts 112a-112d are external contacts and
connector 110 does not include an exposed cavity in which particles and debris may collect.
To improve robustness and reliability, connector 110 is fully sealed and includes no moving
parts. Furthermore, connector 110 has a considerably reduced insertion depth and insertion
width as compared to commonly available TRS and TRRS connectors. In one particular
embodiment, tab 52 of connector 50 has a width, X, of about 2 mm; a thickness, Y, of about
1 mm; and a insertion depth, Z, of about 4 mm. In another embodiment, tab 52 of connector
50 has a width, X, of 4.1 mm; a thickness, Y, of 1.5 mm; and a insertion depth, Z, of 5.75

[0136] Reference is now made to Figs. 15A-15E, which show perspective views of
connector 110 at various stages of manufacture. As shown in Fig. 15A, within connector 110
is a dielectric frame 120 that supports contacts 112a-112d. Frame 120 can be made from any
appropriate dielectric material, such as polypropylene, and includes respective slots (not
labeled) on the upper and lower surfaces of the frame through which each of contacts 112a-
112d are threaded to better support the contacts. In other embodiments, frame 120 can be
made from a ceramic material and contacts 112a-112d can be printed directly onto the frame.

[0137] Frame 120 also includes grooves 122 partially surrounding an outer periphery at a
distal tip of the frame as well as reliefs 124a, 124b that are positioned to align with notches
104a, 104b formed in the metal ground ring 102. Wires 126, one per contact, extend from a
cable 43 are soldered to connection pads 128a-128d for each of the contacts 122a-112d as
shown in Fig. 15B. The metal ground ring 102, which in the embodiment shown in Fig. 15C
is a U-shaped frame die cast from stainless steel, is then slid over the distal end of the
connector such that slots along an interior side 122 and a base portion 102b of the ground ring covers the soldered connection pads 128a-128d electrically coupled to contacts 112a-112d.

[0138] The connector is then overmolded (Fig. 15D) with thermoplastic polymer 130 or similar material to provide strain relief and insulation 132, e.g., POM, is injected around the contacts. Finally, an ABS or similar shell 134 is positioned over and fastened or bonded to the base 102(b) of the tab 102 as shown in Fig. 15E using an appropriate adhesive or other technique to form body 42 and complete formation of the connector.

[0139] In another embodiment, the conductive ground ring 102 can be made from a high strength steel alloy or similar material. The ground ring can be formed in an extrusion process where the high strength conductive material is extruded through a mushroom shape mold to form a straight metal piece 135 having a mushroom shaped cross-section as shown in Fig. 16A. A stem section 136 of the ground ring can be designed to mate with grooves 122 positioned along the outer periphery of dielectric frame 120 when the ground ring is attached to frame 120. Extruded piece 135 can then be cut to length and notched to form u-shaped notches 104a, 104b that align with reliefs 124a, 124b in frame 120 prior to being bent into the U-shape ground ring 102 as shown in Fig. 16B. Stem section 136 of the U-shaped ground ring 102 can then be aligned with grooves 122 of the dielectric frame so that the ground ring can be slid over the end of frame 120 and welded, glued or otherwise bonded to the various components of the connector (the particular bonding method being selected based on the materials being connected) as shown in Fig. 16C, which for simplicity omits various features of the connector such as contacts 112a-112d.

[0140] Fig. 17A is a simplified perspective view of an audio plug connector 140 according to another embodiment of the present invention. Connector 140 is similar to connector 110 except that it has been reinforced at the base of tab 44 to stiffen the connector and increase its strength in a side-load condition. Specifically, connector 140 has a thicker base portion 102(b) underneath outer shell 134 that forms body 42. A chamfered edge 142 extends between the thicker base portion to a connector portion of tab 44. To keep the insertion depth, Z, of the connector the same as that of connector 110, each of the contacts 112a-112d have a reduced length in connector 140 as compared to connector 110. While none of the figures herein are not meant to represent exact dimensions of the connectors, the reduced
length can be seen generally by comparing 110.

[0141] Fig. 18, is a simplified cross-sectional view of connector 140 along lines A-A' shown in Fig. 17D. As evident from the cross-sectional view, ground ring 102 forms a tip 143 of the connector as well as chamfered edge 142. Insulators 144 and 145, which can be a single part or separate parts and can be made from a thermoplastic or similar material, encircle the base and tip of the tab portion of connector 140, respectively, for cosmetic purposes. Insulator 144 also extends within the body of connector 140, underneath ground ring 102 to provide the thicker base portion. In one particular embodiment, insulators 144, 145 are made from polyoxymethylene (POM) plastic. A dielectric frame 148 runs through connector 140 to provide support for contacts 112a-112d. Wires 146 are soldered to each of the contacts 112a-112d within a cavity 149 formed at a connection pad coupled to the contacts that is surrounded by overmolding 147. In other embodiments, shown as separate examples in Figs. 19A and 19B (which show an expanded view of chamfer portion 142 of tab 44 along with a portion of outer shell 134), insulator 144 interlocks with the ground ring to provide a more secure connection between insulator 144 and the ground ring.

[0142] Reference is now made to Fig. 20A, which is a simplified perspective view of a four contact plug connector 150 according to another embodiment of the invention. Connector 150 is generally similar to connector 110 shown in Fig. 14a except that body 42 and tab 44 of connector 150 have features that are generally more rectangular than similar features in connector 110 and connector 150 includes pockets 152 formed on the sides of tab 44 as retention feature rather than semi-circular notches. As shown in Fig. 20A, the edges of body 42 of connector 150 are less rounded and more rectangular than those of body 42 of connector 110. Similarly, the edges of tab 44 in connector 150 are also less rounded and more rectangular than those of tab 44 in connector 110 and the tab in connector 150 is shorter and stubbier than that of connector 110.

[0143] Indentations or pockets 152a, 152b on each side of the connector in ground ring 102 act as retention features, and function similarly to notches 104a, 104b in connector 110. Pockets 152a, 152b are adapted to operatively engage with a retention mechanism when the connector is mated with a corresponding receptacle connector. The retention mechanism fits within pockets 152a, 152b and provides a retention force that secures connector 100 to the matching receptacle connector. In addition to their retention feature, pockets 152a, 152b are
part of metal ground ring 102 and serve as § described with respect to Figs. 3A and 3B.

[0144] Reference is now made to Figs. 20B, which is an exploded view of connector 150, along with Fig. 21, which is a flow chart that illustrates steps associated with the manufacture of connector 150 according to one embodiment of the invention, and Figs. 22A-22G, which depict connector 150 at the various stages of manufacture set forth in Fig. 19. The manufacture of connector 150 can start with the construction of a flex circuit 160 having flex contacts 162a and 162b formed on an upper surface and a similar pair of flex contacts (not shown in the figures) formed on a lower surface as shown in Fig. 22A (Fig. 21, step 170).

Flex contact 162a is electrically coupled to a solder landing 164a where a signal wire can be soldered to the contact by a trace (not shown) on the flex circuit. Similarly, flex contact 162b is electrically coupled to a solder landing 164b by a trace on flex circuit 160.

[0145] In one embodiment, flex circuit 160 is made from two substantially identical flex circuits 160a, 160b adhered together. For example, a first flex circuit 160a with flex contacts 162a and 162b formed on its upper surface and no contacts formed on its opposing surface is adhered to a second flex circuit 160b with two flex contacts (not shown but similar to contacts 162a and 162b) formed on its upper surface and no contacts formed on its opposing surface. The two surfaces without the contacts are then joined together to form an assembled flex circuit 160 that has flex contacts 162a, 162b on a first surface and two matching contacts 162c, 162d on its opposite surface.

[0146] Contact pucks 166a and 166b can then be attached to the flex circuit at contact areas 162a, 162b, respectively, while contact pucks 166c and 166d can be attached to contact areas on the other side of flex circuit 160 (Fig. 21, step 172 and Fig. 22B). Pucks 166a-166d can be made from a variety of conductive materials and in one embodiment are nickel-plated brass. Pucks 166a-166d can be cut to size in a stamping or similar process from a metal sheet and can be attached to flex circuit 160 using surface mount technology. Next, flex circuit 160 can be inserted into ground ring 102 (Fig. 21, step 174 and Fig. 22C) and a thermoplastic or similar dielectric overmold 163 can formed around the contacts to provide smooth and substantially flat upper and lower surfaces of tab portion 44 of the connector and provide a finished look (Fig. 21, step 176 and Fig. 22D). In one embodiment, dielectric overmold 163 is formed with an injection molding process using polyoxymethylene (POM).
A cable bundle 43 having four inc
each of the contacts of connector 150, can then be attached to the ground ring/flex circuit
assembly as shown in Fig. 22E by soldering each of the wires 161 to its respective solder
landing, e.g., solder landings 164a-164d (Fig. 21, step 178). At this stage of manufacture the
end of a jacket 157 of cable bundle 43 is spaced apart from flex circuit 160 in an oppositional
relationship. An inner dielectric jacket 165 is then formed around much of the assembly
using an injection molding or similar process (Fig. 21, step 180 and Fig. 22F). Inner jacket
15
10
10
15

includes a generally circular end portion 167 that covers a couple centimeters or more of
cable bundle 43 and a connector portion 169 that, combined with ground ring 102, forms a
structure and strain relief for connector 150 and can be made from a dielectric material such
as an elastomer or a polypropylene material.

The construction of connector 150 can then be completed by sliding an outer shell
134 around the monolithic base portion 159 covering an end base portion 102b of ground ring
and inner jacket 165 (Fig. 20, step 182 and Fig.219G). Outer shell 134 can be adhered to
the ground ring and inner jacket using any appropriate adhesive suitable for the particular
materials being bonded.

Fig. 23A is a simplified perspective view of a plug connector 190 according to
another embodiment of the invention. Connector 190 includes many features similar in
design and function as that of connector 150 discussed above. For example, connector 190
includes a tab 44 having four contacts 112a-112d formed at its outer surface and arranged on
opposing sides of the connector. Tab 44 includes a ground ring 102 that surrounds contacts
112a-112d and includes indentations or pockets 152a, 152b of each side of the connector tab
are adapted to operatively engage with a retention mechanism when the connector is mated
with a corresponding receptacle connector. Connector 190 differs from connector 150 by
including a chambered edge 192 between the tab and the body that strengthens the connector
under side-load forces similar to chamfered edge 142 of connector 140.

Reference is now made to Figs. 23B, which is an exploded view of connector 190,
along with Fig. 24, which is a flow chart that illustrates steps associated with the manufacture
of connector 190 according to one embodiment of the invention and Figs. 25A-25H, which
depict connector 190 at the various stages of manufacture set forth in Fig. 24. The
manufacture of connector 190 can start with the formation of a contact frame 194 that carries
four contact strips 196a-196d, one for each
made from a dielectric material and in one particular embodiment is formed from a liquid
crystal polymer using an injection molding process. Contact strips 196a-196d can be
stamped from a sheet of metal such as phosphor bronze and threaded into grooves 198a-198d
formed in contact frame 194 as shown in Fig. 25A (Fig. 24, step 210).

[0151] Contact pucks 204a and 204b can be attached to one end of contact strips 196a and
196b, respectively, while contact pucks 204c and 204d can be attached to the corresponding
ends of contact strips 196c and 196d (Fig. 24, step 212 and Fig. 25B). Pucks 204a-204b can
be made from a variety of conductive materials and formed in a variety of different manners.

In one particular embodiment, pucks 204a-204d are stamped from a sheet of nickel-plated
brass and laser welded to their respective contact strips. Next, contact frame 194 can be
inserted into ground ring 102 (Fig. 24, step 214 and Fig. 25C) and a thermoplastic or similar
dielectric overmold 200 can formed around the contacts to provide smooth and substantially
flat upper and lower surfaces of the tab portion of the connector and provide a finished look
(Fig. 24, step 216 and Fig. 25D). In one embodiment, dielectric overmold 200 is formed
from polyoxymethylene (POM) in an injection molding process.

[0152] Next, a cable bundle 43 having four individual insulated signal wires 161, one for
each of the contacts of connector 190, is attached to the ground ring/contact frame assembly
as shown in Fig. 25E by soldering each of the wires 161 to its respective contact strip (Fig.
24, step 218). An inner dielectric jacket 202 is then formed around much of the assembly
using an injection molding or similar process (Fig. 24, step 220 and Fig. 25F). Inner jacket
202 includes a generally rounded or oval end portion 167 that covers several centimeters or
more of cable bundle 161 and a connector portion 169 that, combined with ground ring 102,
forms a substantially monolithic base portion 159 of connector 190. Inner jacket 202 helps
provides strain relief for connector 190 and can be made from a dielectric material such as an
elastomer or a polypropylene material. The construction of connector 190 can then be
completed by sliding an outer shell 134 around an end base portion 102b of ground ring 102
and inner jacket 202 (Fig. 24, step 222 and Fig. 25G). Outer shell 134 can be adhered to the
ground ring and inner jacket using any appropriate adhesive suitable for the particular
materials being bonded.

[0153] Fig. 26A is a simplified perspective view of a four contact plug 230 according to
still another embodiment of the invention and Fig. 26B is an exploded view of connector plug
230. Connector 150 includes many features above with respect to Figs. 20A and 23A, respectively. Connector 123 differs from these connectors in that the body of connector 230 and tab portion 44 of the connector that is designed to be inserted within a corresponding receptacle connector are combined as a single monolithic (though relatively small) piece with a uniform cross-sectional shape. Additionally, a portion of connector 230 is relatively flexible. Specifically, connector 230 includes a rigid connector or tip portion 232 and a flexible base portion 234. In this particular embodiment, rigid portion 232 is approximately one third the length of the connector while flexible portion 234 is approximately two thirds the length. In other embodiments, however, the ratio between the flexible and rigid tip portion may differ considerably.

[0154] The tip 232 of connector 230 includes a ground ring 102 that surrounds contacts 112a-112d at the tip and sides of the connector. Ground ring 102 can be made from any appropriate metal or other conductive material and in one embodiment is stainless steel plated with copper and nickel. When fully inserted, the entirety of rigid portion 232 is within the receptacle connector along with a portion 132 of the flexible portion 234 of connector 230.

[0155] The flexible base portion 234 of connector 230 can be made from a flexible dielectric material such as an elastomer or a polypropylene material which enables the connector to flex along the length of the connector to at least a point where the ground ring begins in order to relieve strain during off angle mating events in a manner similar to that described with respect to Figs. 11A and 11B. In one specific example, base portion 234 is made from Arnitel EL250 available from DSM Engineering. Connector 230 also includes indentations or pockets 152a, 152b on each side of the connector in ground ring 102 as described above.

[0156] Reference is now made to Figs. 27A-27G, which depict connector 230 at various stages of manufacture. Contacts 112a-112d are formed from a flex circuit 235 upon which contact pucks 236a-236d are attached. Pucks 236a-236d can be made from a variety of conductive materials and in one embodiment are brass. Pucks 236a-236d can be cut to size in a stamping or similar process from a metal sheet and can be attached to flex circuit 235 using surface mount technology (SMT) as shown in Fig. 27A. In a separate step, ground ring 102 can be secured to the body of connector 230 by retention clips 238 which can be made out of the same stainless steel or other metal as the ground ring and laser welded at locations 239 or otherwise connected to ground ring 102 as shown in Fig. 27B. Retention clips 238 have an
anchor at one end that extends beyond the g
secure the ground ring to the connector body as described more fully below.

[0157] Once the ground ring/retention clip and flex circuit/contact puck assemblies are
made, the flex circuit assembly can be inserted into and adhered to the ground ring with an
appropriate adhesive as shown in Fig. 27C. Next, a metal ground bridge 240 and weld puck
242, each of which, for example, can be brass, are soldered together and attached to the flex
circuit between opposing ends of retention clips 238 as shown in Fig. 17D. A cable 43 with
signal wires 171 is then soldered to contacts 245, which are electrically connected to and
carry signals from respective contacts 152a-152d (Fig. 27E). As shown in Fig. 27E, cable 43
has a generally flat portion that is spaced apart from flex circuit 235 in an oppositional
relationship. An inner dielectric jacket 246 is formed around much of the assembly using an
injection molding or similar process as shown in Fig. 27F. Inner jacket 246 extends from the
substantially flat end of cable 43 to retention clips 238 and provides structural strength to
connector 230 covering signal wires 171 and a portion of flex circuit 235. Inner jacket 246
can be made from a flexible dielectric material such as an elastomer or a polypropylene
material just like outer jacket 244, and in one particular embodiment, is made from the same
material as the outer jacket.

[0158] The construction of connector 230 can then be completed by forming outer jacket
244 around an end portion of cable 170, inner jacket 246 and the other connector components
using an injection molding or similar process forming the substantially rectangular connector
plug 230. As shown in Fig. 27G, outer jacket 244 fills in the gaps between the contact pucks
and covers anchors 230 filling the semicircular space between each anchor end thereby fully
securing ground ring 102 and components connected to the ground ring to the connector
body.

[0159] Reference is now made to Fig. 28A, which is a simplified perspective view of one
embodiment of a receptacle connector 250 that can be used in conjunction with certain plug
connectors according to the present invention. Connector jack 250 includes a housing 252
that defines an interior cavity 254 into which a plug connector, such as connector 40, can be
inserted. One or more contacts extend into cavity 254 from each of the upper and lower
interior surfaces of the cavity, the number of which depends on the type of plug connector
receptacle connector 250 is intended to be used with. For example, receptacle connector 250
can be designed to mate with a four contact plug connector such as connector 110 shown in
Figs. 14A-14D and thus includes four contacts opposing interior surfaces of cavity 254 and can be designed to mate with a four contact plug connector such as connector 110 shown in Figs. 14A-14D. In other embodiments, connector jack 250 may include any number of contacts, from pairs of one to twenty or more arranged on opposing surfaces of cavity 254 in a variety of different patterns that match the contact locations of a particular plug connector. As examples, receptacle connector 250 may include contacts at both the upper and lower interior surfaces of cavity 254 that are positioned to electrically couple with contacts arranged on a plug connector according to any of the contact patterns shown in Figs. 5A-5H as well as other contact patterns.

[0160] As seen in Fig. 28B, which is a front view of connector jack 250, in one particular embodiment receptacle connector 250 includes four contacts 256a-256d positioned to electrically couple to appropriate contacts in the corresponding plug connector, for example to contacts 112a-112d in connector 110. Thus, contacts 256a-256d are arranged in a symmetric manner complementary of contacts 112a-112d of the plug connector.

Additionally, cavity 254 is shaped so that the plug connector can be inserted into the cavity in either of two orientations: a first orientation in which plug connector contacts from region 46a (contacts 112a, 112b) electrically couple to the receptacle connector contacts protruding from an interior upper surface of the cavity and a second orientation in which plug connector contacts from region 46b (contacts 112c, 112d) electrically couple to the receptacle connector contacts protruding from the interior upper surface. Circuitry within receptacle connector jack 250 detects the orientation of the plug connector and sets software switches to properly match the contacts to the plug connector’s contacts. For example, a first software switch can be used to switch the connector jack’s contacts for left and right audio depending on the insertion orientation while a second software switch can be used to switch the connector jacks microphone and ground contacts to match the contacts of connector 120.

[0161] To facilitate the dual orientation insertion, upper and lower portions of cavity 254 (as defined by a plane 255 that horizontally bisects the cavity as shown in Fig. 28B) can be mirror images of each other. Left and right portions of cavity 254 (as defined by a similar plane that vertically bisects the cavity) can also be mirror images of each other. Additionally, receptacle connector 250 does not include polarization keys that limit a mating event between the plug and receptacle connectors to a single orientation.
[0162] In some embodiments receptacle c

to not allow ingress of moisture into whatever electronic device the connector is housed within. Also, a hole (not visible in the drawing) within the interior of cavity 254 allows a spring-loaded retention mechanism 258 to protrude into the cavity. As shown in Fig. 28C, which is a bottom plan view of receptacle connector 250, retention mechanism 258 includes a spring 260 positioned in a cut-out section 262 of the housing. Spring 260 is pre-loaded so that a tip 264 extends through an opening between cut-out 262 and cavity 254. When plug connector 110 is inserted into cavity 254, spring 260 latches with either retention feature 104a or 104b of the connector plug depending on its insertion orientation. In some

embodiments, spring 260 can be made from metal and also act as a ground contact for receptacle connector 250.

[0163] As previously discussed, retention features 104a, 104b can be located near the distal end of connector 110. The inventors have determined that positioning the retention features near the end of the plug connector (and thus positioning the and corresponding retention mechanism near the rear of cavity 254) helps to better secure the plug connector sideways when it is in an engaged position within receptacle connector 250. Furthermore, the shape of the retention features on the plug connector can match the shape of retention mechanism 258 to provide a comfortable click feel when the retention mechanism engages the retention feature. For example, the rounded bulbous shape of retention features 104a, 104b of connector 110 can match the rounded shape of the tip 264 of spring 260 to provide a secure engagement between the structures. Fig. 29 shows plug connector 110 inserted into connector jack 250 where one of retention features 104a, 104b is engaged with spring 260.

[0164] In Figs. 28A-28C, the overhead of contacts 256a-256d of receptacle connector 250 is placed at the ends of the contacts as illustrated schematically in Fig. 30A, which shows contacts 256a, 256b of receptacle connector 250 and their associated contact overhead 268 in relation to a plug connector 110 having contacts 112a, 112b operatively coupled to the receptacle jack. In other embodiments, the overhead of the contacts can be placed at the sides of the receptacle connector contacts as shown in Fig. 30B or above and below the contacts as shown in Fig. 30C, which is a simplified side view of plug connector 110 mated with contacts in a receptacle connector (where, for ease of illustration, only the contacts of the receptacle connector are shown in a schematic representation).
[0165] Fig. 31A is a front view of receptacle embodiment of the invention. Receptacle connector 270 is similar to receptacle connector 250 except, among other differences, in the shape of cavity 254, which is generally more rectangular than that of connector 250, and that connector 270 includes first and second retention mechanisms 272a and 272b protruding into cavity 252 from opposing side surfaces of the cavity instead of a single retention mechanism. Each of retention mechanisms 272a, 272b may include, for example, a spring that is pre-loaded so that a tip of the retention mechanism extends through an opening in each sidewall of the cavity 254. When a plug connector is inserted into cavity 254, the retention mechanisms 272a, 272b latch with retention features, such as notches 104a, 104b or pockets 152a, 152b of one of the plug connectors discussed above. Retention mechanisms 272a, 272b can be located directly opposite each other within cavity 254 and can be designed to impart a retention force on the plug connector that is approximately equal at each side. Similar to retention mechanism 258, the shape of retention mechanism 272a, 272b can match that of the plug connector retention features to provide a comfortable click feel when the retention mechanisms and features engage with each other.

[0166] Fig. 31B is a top plan view of connector jack 270. As shown in Fig. 31B, each of the receptacle contacts 256a-256d includes a contact tip, 274a-274d, respectively, that can be bonded to a wire that electrically connects the contact to circuitry associated with the electrical device in which receptacle connector 270 is housed. For example, connector jack 270 can be part of a portable media device and electronic circuitry associated with the media device is electrically connected to receptacle connector 270 via contact tips 274a-274d.

[0167] As described above, various embodiments of the invention pertain to a connector system having 180 degree symmetry. Thus, cavity 254 can be symmetrical with respect to both vertical and horizontal bisecting planes as discussed above. Additionally, contacts 256a and 256b can be directly opposite contacts 256c and 256d so that a plug connector, such as connector 230, can be inserted into jack 270 in either of two orientations. In a first orientation, plug connector contacts 112a, 112b are respectively coupled to receptacle contacts 256a, 256b and contacts 112c, 112d are respectively coupled to receptacle contacts 256c, 256d. In a second orientation opposite the first orientation, plug contacts 112a, 112b are coupled to receptacle contacts 256d, 256c, while plug contacts 112c, 112d are coupled to receptacle contacts 256b, 256a.
[0168] While many of the embodiments in the included figures as four contact connectors, embodiments of the invention are not limited to any particular number of contacts. To further underscore this, reference is now made to Figs. 33A-33D, which depict various views of a twelve contact plug connector 300 according to one embodiment of the present invention. Specifically, Fig. 33A is a simplified perspective view of plug connector 300 while Figs. 33B-33D are simplified bottom, front and side plan views, respectively. Connector 300 includes many of the same features as connector 150 except it has six contacts 302(1) and 302(6) positioned within contact region 46a and an additional six contacts 302(7) and 302(12) positioned within region 46b on the opposing surface of tab 44. The contacts can be made from a copper, nickel, brass, a metal alloy or any other appropriate conductive material. Spacing is consistent between each of the contacts on the front and back sides and between the contacts and the edges of the connector providing 180 degree symmetry so that plug connector 300 can be inserted into a corresponding receptacle connector in either of two orientations as discussed above.

[0169] A significant portion of tab 44 is including its shape is defined by ground ring 102 that extends from a distal tip of the connector towards the outer shell and partially surrounds contacts 302(1), 302(12), along an outer periphery of tab 44. Ground ring 102 can be made from any appropriate metal or other conductive material and in one embodiment is stainless steel plated with copper and nickel. Two indentations or pockets 152a and 152b are formed in ground ring 102 and located on opposing sides 56c and 56d of the tab near its distal end as with connector 150. In one particular embodiment, tab 44 of connector 300 has a width, X, of 4.0 mm; a thickness, Y, of 1.5 mm; and an insertion depth, Z, of 5.0 mm. It is understood that the dimensions of connector 50 as well as the number of contacts may vary in different embodiments.

[0170] When connector 300 is properly engaged with a receptacle connector each of contacts 302(1)-302(12) is in electrical contact with a corresponding contact in the corresponding receptacle connector. Tab 52 has a 180 degree symmetrical, double orientation design which enables the connector to be inserted into a connector jack in both a first orientation where surface 44a is facing up or a second orientation where surface 44b is facing up. In the first orientation, plug connector contacts 302(1)-302(6) couple to receptacle contacts 366(1)-366(6), respectively, and contacts 302(7)-302(12) couple to receptacle contacts 366(7)-366(12), respectively. In the second orientation opposite the first orientation, plug
contacts 302(4), 302(6) couple to receptacle 302(12) couple to receptacle contacts 366(11), 366(6).

[0171] To facilitate the orientation agnostic feature of connector 300, contacts 302(11), 302(12) are arranged such that similarly purposed contacts are located on opposite sides of the connector in a cater cornered arrangement. As an example, reference is made to Fig. 34A, which is a diagram depicting pin locations of connector 300 according to one specific embodiment of the invention having two contacts designated for power, two contacts designated for analog audio signals and eight contacts designated for differential data signals including two USB data contacts, and six display port contacts.

[0172] As shown in Fig. 34A, when a midpoint line 305 dividing connector tab 44 into equal top and bottom halves and a midpoint line 306 dividing the connector tab 44 into equal left and right halves are considered, the contacts associated with connector 50 can be divided into four quadrants labeled clockwise from the top left portion of the connector as quadrants I, II, III and IV, respectively. Quadrants I and III are located in a cater cornered arrangement as are quadrants II and IV. Individual contacts within the cater cornered quadrants can be arranged, based on their function, in a mirrored relationship. For example, the two contacts in quadrants I and III closest to midpoint line 61, contacts 302(3) and 302(9), are each dedicated for power. Similarly the two outermost contacts in these quadrants are dedicated for a pair of differential data signals. In quadrants, II and IV, the innermost contact, contacts 302(4) and 302(10) are each dedicated for analog audio signals while the two outermost contacts in each quadrant dedicated for a pair of differential data signals.

[0173] As evident from a comparison of Figs. 34A and 34B, which depict the pinout of connector 300 in two different orientations (in Fig. 34A surface 44a is facing up while in Fig. 34B surface 44b is facing up), regardless of which of the two possible orientations that connector 300 is inserted into its receptacle connector, the contact order on the top side of the connector, from left to right, is always as follows: the first two contacts are designated for a pair of differential data signals, the third contact is designated for a power contact, the fourth contact is designated for an audio contact and the fifth and sixth contacts are designated for another pair of differential data signals. Similarly, the contact order on the bottom side of the connector, from left to right, is always as follows: the first two contacts are designated for a pair of differential data signals, the third contact is designated for an audio contact, the fourth
contact is designated for a power contact ar
another pair of differential data signals.

[0174] Reference is now made to Figs. 35-38. Fig. 35 is an exploded view of connector
310 for a synchronization and charging cable that has the same form factor as connector 300
(and thus will operatively engage with the same set of receptacle connectors as plug
connector 300) including the same number of contacts. As a sync and charge cable, however,
the contact locations dedicated for audio contacts and display port contacts are not needed
and thus are not made operational in this particular embodiment. Fig. 37 is a flow chart that
illustrates steps associated with the manufacture of connector 310 according to one
embodiment of the invention and Fig. 38A-38P depicts connector 310 at the various stages of
manufacture set forth in Fig. 37.

[0175] The manufacture of connector 310 can start with the construction of printed circuit
boards 312a and 312b (Fig. 37, step 330) each of which includes six contact areas that,
together, correspond to contacts 302_{(1)}-302_{(12)}. Figs. 36A and 36B more clearly show a top
plan view and side plan view, respectively, of PCB 312a. Contact pucks are attached to the
contact areas of PCB 312a to form contacts 302_{(1)}-302_{(6)}. The contact pucks can be made
from a variety of conductive materials and in one embodiment are nickel-plated brass. The
pucks can be cut to size in a stamping or similar process from a metal sheet and can be
attached to PCB 312a using surface mount technology. As shown in Fig. 36A, PCB 312a
includes wire solder pads 315 that are electrically coupled to corresponding contact areas. As
noted above because connector 310 is a sync and charge cable, connector 310 does not
include electrical connections for audio contacts 302_{(4)} and 302_{(10)}, nor does it include
electrical connections for display port contacts 302_{(7)}-302_{(8)} and 302_{(11)}-302_{(12)}.
Instead, contacts formed in those locations are not coupled to solder pads on the PCBs and
are thus not functional. This is evidenced in Fig. 36A which shows USB contacts 302_{(5)}-
302_{(6)} and power contact 302_{(3)} coupled to corresponding solder pads via electrical traces
while contacts 302_{(1)}, 302_{(2)} and 302_{(4)} are not connected to electrical traces and are not
connected to any of solder pads 315. In other embodiments, all of contacts 302_{(1)}-302_{(12)} may
be operatively coupled to solder pads on the PCBs or different subsets of contacts may be
coupled depending on the purpose of the connector.

[0176] After each of the PCBs 312a, 312b are constructed and the contacts attached, the
PCBs are inserted through the front side of ground ring 102 via the top and bottom openings
of the ground ring that surround the contact
314 is sandwiched between the two PCBs 312a, 312b by inserting the ground plate from the
back of ground ring 102 (Fig. 38G). Ground plate 314 provides a thick layer of shielding
between contacts 302(1)-302(6) formed on PCB 312a and contacts 302(7)-302(12) formed on
PCB 312b.

[0177] The assembled ground ring/PCB/ground plate structure (Fig. 38H) is then placed in
a molding tool and a thermoplastic or similar dielectric overmold 316 can be formed around
the contacts to provide smooth and substantially flat upper and lower surfaces of the tab
portion of connector 310 and provide a finished look (Fig. 37, step 334; Fig. 38I). In one
embodiment, dielectric overmold 316 is formed with an injection molding process using
polyoxymethylene (POM).

[0178] A cable bundle 318 having individual signal wires 320, one for each of the
functional contacts of connector 310 as well as one or more ground wires to be coupled to
ground ring 102 can be prepared at this time or prior to step 330 (Fig. 38J). The individual
signal wires are cut and stripped, the jacket of the cable bundle is stripped and the cable
shields are folded back over the jacket. Next, a cable crimp 322 having a bottom metal shield
is secured to the cable bundle (Fig. 37, step 336; Fig. 38K). The cable bundle can then be
attached to the ground ring/PCB assembly as shown in Fig. 38L by soldering each of the
signal wires to its respective solder pad and soldering the ground wires to the ground ring
(Fig. 37, step 338). The solder joints and exposed wires can then be potted with a UV glue to
further secure the connections.

[0179] At this stage of manufacture the end of cable bundle 318 is spaced apart from the
PCB assembly in an oppositional relationship and positioned above bottom metal shield 312
and between two opposing ends of ground ring 102. A metal top shield 314 can be attached
to the top of ground ring 102 (Fig. 38M) and the top and bottom metal shields are laser
welded or similarly attached to ground ring 102 to form an enclosure or box around the cable
bundle (Fig. 37, step 340). Next, a dielectric trim piece 326 can be slid over the end of tab
102 and glued to the exposed front of ground ring 102 (Fig. 37, step 342; Fig. 38N). As
shown in Fig. 38N, dielectric trim includes two rails 326a, 326b that slide into corresponding
grooves in ground ring 102 and includes a front face 326c that is sized to have the same width
and height as the base of ground ring 102. In one embodiment trim piece 326 can be made
from ABS plastic or a similar dielectric material.
An inner dielectric strain relief jacket assembly using an injection molding or similar process (Fig. 37, step 344; Fig. 38O). Strain relief jacket 328 can include a generally circular end portion 328a that covers a centimeter or more of cable bundle 318 and a block portion 328b that completes and fills in gaps in the metal enclosure formed by ground ring 102, bottom shield 322 and top shield 324 thereby forming a substantially monolithic base portion 90 of connector 310 that is effectively sealed. Strain relief jacket 328 provides structure and strain relief for connector 310 and can be made from a dielectric material such as an elastomer or a polypropylene material.

The construction of connector 310 can then be completed by sliding an outer shell 134 around the monolithic base portion covering an end portion of ground ring 102, trim piece 326 and strain relief jacket 328 (Fig. 37, step 346; Fig. 38P). Outer shell 134 can be formed from ABS or a similar dielectric material and adhered to the ground ring and inner jacket using any appropriate adhesive suitable for the particular materials being bonded.

Figs. 39A-39D show top, perspective, front and side views of a receptacle connector 360 according to one embodiment of the invention designed to have a reduced width as compared to depth. Receptacle connector 360 includes a housing 362 that defines a cavity 364 and houses twelve contacts 366(1)-366(12) within the cavity. In operation, a connector plug, such as plug connector 300 can be inserted into cavity 364 to electrically couple the contacts 302(1)-302(12) to respective contacts 366(1)-366(12). Positioned along the sides of the interior of cavity 364 are two spring-loaded conductive retention clips 368a, 368b that protrude into the cavity and function to both secure the plug connector within the cavity and provide a ground for the connector.

Retention mechanisms 368a, 368b may include, for example, a metal spring that is pre-loaded so that a tip of the retention mechanisms extend through an opening in each sidewall of the cavity 364. When a plug connector is inserted into cavity 364, the retention clips 368a, 368b latch with pockets 152a, 152b, respectively, of the connector plug. The shape of retention mechanism 368a, 368b matches that of pockets 152a, 152b to provide a comfortable click feel when the retention clips engage with the pockets. In one embodiment, the depth and position of the pockets is selected to provide specific insertion and extraction forces such that the retention force required to insert the plug connector into receptacle connector 360 is higher than the extraction force required to remove the plug connector from the receptacle connector. Also, in one embodiment, retention clips 368a, 368b are located
near the back surface of cavity 364. The in
retention clips near the back of the cavity, which requires pockets 152a, 152b on the plug
connector to be positioned near its distal end, helps to better secure the connector sideways
when it is in an engaged position within connector jack 360.

5 [0184] Each of the receptacle contacts 366(1)-366(12) electrically connects its respective plug
contact to circuitry associated with the electrical device in which receptacle connector 360 is
housed. For example, receptacle connector 360 can be part of a portable media device and
electronic circuitry associated with the media device is electrically connected to jack 360 by
soldering tips of contacts 366(1)-366(12) that extend outside housing 362 to a multilayer board
such as a printed circuit board (PCB) within the portable media device. Additionally, each of
the conductive retention clips 368a, 368b can be electrically coupled to a ground path
associated with connector 360. As an example, in one embodiment, pins at a back end of
retention clips 368a, 368b can be soldered to bonding pads formed on the multilayer board or
PCB associated with the portable media device that are coupled to ground.

10 [0185] Figs. 40A-40D show top, perspective, front and side views of a receptacle connector
370 according to another embodiment of the invention designed to have a reduced depth as
compared to width. Except for the dimensions of housing 363, the components of connector
370 are similar to those of connector 360 and are thus referred to with the same reference
numbers.

15 [0186] In one embodiment, each of receptacle connectors 360 and 370 can be formed using
the process depicted in Fig. 41. For example, contacts 366(1)-366(12) can be formed from lead
frames stamped from an appropriate metal such as nickel-coated brass (Fig. 41A). The
contacts can be arranged and spaced apart in a mold and insert molded within dielectric
blocks 369 made from a thermoplastic or similar material to form two separate sets of
contacts (Fig. 41B). Each of the contact sets can then be attached at top and bottom interior
surfaces of housing 362 (Fig. 41C) so that a front end of the contact extends into cavity 364
formed by the housing and a back end of the contact extends out of the back of the housing so
that it can be soldered to a bonding pad (not shown) formed on a printed circuit board or
similarly electrically connected to desired circuitry associated with the electronic device in
which the receptacle connector is housed.

20 [0187] Retention clips 368a, 368b can similarly be formed using a metal stamping process
and assembled to the sides of housing 362 (Fig. 41D). Retention clips 368a, 368b can

30
include pins 367 that extend out past a back
ground the retention clips to the electrical device in which receptacle connector 360 is housed
as discussed above. Next, the partially assembled receptacle connector can be placed in a
mold and liquid silicone rubber can be injected around the housing to form a boot 380 that
seals the receptacle connector (Fig. 41E). Top and bottom metal shells 382 and 384 can then
be attached over silicone rubber boot 380 to the top and bottom of housing 362, respectively,
and laser welded together to form an outer enclosure that provides additional shielding for the
connector (Fig. 41F). Finally, a conductive EMI gasket 386 can be attached to the front of
the housing to further seal the connector when receptacle connector and the plug connector
are mated (Fig. 41G).

[0188] Fig. 42 is a simplified perspective view of a connector plug 390 according to
another embodiment of the invention in which a ground ring is not employed. Instead,
connector 390 is made from two printed circuit boards 392a, 392b sandwiched around a
structural conductive member 264, such as a brass plate. A tab portion 395 extends out of
body 42 and has the same form factor as tab 44 of connector 300 shown in Fig. 32 including
the same twelve contacts (six on an upper surface of connector 390 and six on a lower
surface) spaced the same distance from the edges of the connector at the same spacing
enabling plug connector 390 to be operatively coupled to the same receptacle connectors such
as plug connector 300.

[0189] Connector 390 does not include a ground ring similar to ground ring 102, however.
Instead, indentations 396a, 396b formed on opposing sides of conductive member 394 match
generally the size and contour of pockets 152a, 152b giving the tab portion of connector 390
a bread loaf shape when viewed from above or below. Indentations 266 provide the
connector the same comfortable click/lock feeling achieved by connector 300 when it is
inserted and removed from a receptacle connector. Also, when mated with a receptacle
connector, conductive member 394 receives a ground connection via the retention clips in the
receptacle connector.

[0190] Another example of a data connector according to the present invention is illustrated
in Fig. 43, which is a perspective view of a connector 400 according to another embodiment
of the invention. Connector 400 includes eight contacts arranged as four pairs of contacts
401, 402 on a first major surface of tab 44 and 403 and 404 (not shown in Fig. 43) on the
opposing major surface. In one embodiment or similarly purposed signals. For example, in one particular embodiment contact pair 401 includes first and second power signals, contact pair 402 includes a first set of positive and negative differential data signals, signal pair 403 includes a second set of positive and negative differential data signals, and contact pair 404 includes a third set of positive and negative differential data signals (contact pairs 403 and 404 are not shown in Fig. 43 but are directly opposite contact pairs 401 and 402). The data contacts can be used to carry any appropriate data signal as well as audio signals, video signals and the like. From an exterior view, other than the number of contacts, connector 400 is similar to connector 300 and includes a ground ring 102, an outer sleeve 216 and pockets 217 that are similar to the components of the same name in connector 300. Additionally, ground ring 102 includes a chamfered edge 192 to increase the strength of the connector.

[0191] Fig. 44A is a simplified perspective cut-away view of connector 400 in which individual contacts 402a and 402b from contact pair 402 are fully visible without surrounding molding or the ground ring. Each of the contacts is attached to a printed circuit board 405 having a ground plane 408 sandwiched between top and bottom dielectric layers 406a and 406b. Contacts 401a, 401b and 402a, 402b are attached to conductive pads (not shown) formed on dielectric layer 406a while contact 403a, 403b and 404a, 404b are attached to conductive pads formed on dielectric layer 406b. Ground plane 408 is thus positioned between the sets of contacts pairs (401 and 404) and (402 and 403) which reduces signal interference that may otherwise occur between the closely spaced contact pairs.

[0192] Fig. 44B is a simplified cross-sectional view of connector 400 through the middle of the contact pairs. As shown in Fig. 44B, contact pairs 401-404 are divided into four quadrants by ground plane 404 and a central rib 415a, which is part of ground ring 102. Rib 415a runs longitudinally through the tab portion of connector 400 dividing the tab into left and right halves with contact pairs 401 and 404 on one half and contact pairs 402 and 403 on the opposite half. Fig. 44B also shows that dielectric overmolding 418 (e.g., a thermoplastic material such as POM) fills in gaps between the individual contacts of each contact pair (e.g., between contacts 401a and 401b) as well as between the contact pairs and ground ring 102 and rib 415a.

[0193] Reference is now made to Fig. 45, which is a simplified partial cut-away perspective view of a plug connector 400 and a receptacle connector jack 420 according to an
embodiment of the invention where plug 420 prior to a mating event. Connector jack 420 includes an outer shell 422 that defines an interior cavity 424 into which the tab portion of plug connector 400 can be inserted. The receptacle connector includes four contact pairs 426-429 that extend into cavity 424 and detents 425 which extend from the opposing sidewalls of jack 420 into cavity 424. When plug connector 400 is inserted into cavity 424, detents 425 engage pockets 152a, 152b to secure the plug connector within cavity 424 and individual contacts in contact pairs 401-404 of the plug connector are electrically coupled to individual contacts of contact pairs 426-429, respectively, of the receptacle connector.

Each of the contacts in contact pairs 426-429 can be insert molded within a dielectric block 429 made from a thermoplastic or similar material with a front end of the contact extending into cavity 424 and a back end extending in the opposite direction towards a back end of the receptacle connector. In Fig. 45 only individual contacts 402b and 404a, 404b of receptacle connector 420 can be seen. The back end of each contact is electrically coupled to a bonding pad (not shown) formed on printed circuit board (PCB) 426. Conductive traces (not shown) on PCB 426 connect the contacts to circuitry associated with the electronic device in which receptacle connector 420 is housed. To reduce signal interference between contacts and improve grounding, receptacle connector 430 includes grounding contacts and a ground plane 428 that generally surround the contact pairs and divide them into quadrants that correspond to the quadrants associated with contacts 401-404. Specifically, a grounding contact can be located between each contact pair and a sidewall of housing 422 while other grounding contacts can be located between contact pairs 403, 404 and 401, 402, respectively. Each of the grounding contacts is positioned to contact a different portion of ground ring 102 when the connectors are mated. Grounding plane 428 is formed on PCB 426 and sandwiched between an upper dielectric layer 426a and a lower dielectric layer 426b. Finally, a conductive gasket 430 provides sealing and environmental shielding when jack 420 and plug connector 400 are mated.

Any of the connectors discussed herein can be modified to include one or more fiber optic cables that extend through the connector and can be operatively coupled to receive or transmit optical data signals between a mating connector jack. As an example, Figs. 46A-46D illustrate one example of a connector 440 having five analog contacts as well as a fiber optic cable 445 that runs through the center of the connector. The analog contacts include contacts 112a, 112c for left and right audio, a contact 112b for microphone, a contact
112d for power, and a contact 222e for gro
rate transmissions and can be used for USB 4.0 compatibility (e.g., 10GB/second data
transfer). With power, audio and data connections, connector 440 can be used to charge a
device while simultaneously providing data and audio functions.

[0196] As shown in Fig. 46D, which is an expanded view of the distal end of connector
440, fiber optic cable 445 terminates at a lens 446 positioned at the distal end of the
connector and secured in place by ground ring 425. Lens 446 can be made from a chemically
strengthened aluminosilicate glass or a similar material that is highly resistant to scratching
and is flush with the external surface of ground ring 425 to prevent debris build-up and
abstraction of light.

[0197] Some embodiments of the invention pertain to connectors specifically designed for
specific functions, for example as required by certain accessories or cable adapters, as
described below with respect to Figs. 47-59. In the described embodiments and unless
otherwise noted, each of the connectors described with respect to Figs. 47-59 includes a
connector tab that is similarly designed in shape and dimensions to tab 44 of plug connector
300 shown in Fig. 32, including contact spacing and side retention pockets, so that the
various connector tabs are generally insertable and useable with the same receptacle
connector as plug connector 300. Also, each of the connectors described in Figs. 47-59
includes a ground ring that enables the connector to be connected to ground via grounded
retention clips in a corresponding receptacle connector as described above.

[0198] As a first example of a specifically purposed connector, Fig. 47 is a simplified
perspective view of a plug connector 500 according to an embodiment of the invention
specifically designed for headphones and other audio applications. Connector 500 includes
four contacts, two contacts on an upper surface of a tab portion 502 of the connector and two
contacts on the lower surface of connector tab 502. The four contacts provide left and right
audio as well as microphone power, and are sized and spaced such that they match the
locations of contacts 302(3) and 302(4) on one side and match the location, size and spacing of
contacts 302(9) and 302(10) on the other side. Thus, as shown in Fig. 49A, the two contacts on
each side can be used to represent power and audio and align (depending on the orientation of
connector 500) with either the power and audio contacts shown in Fig. 34A or shown in Fig.
34B. In one embodiment, circuitry associated with an electronic device in which connector
500 can be plugged into allows the contacts to be used in a backward compatible mode where
the power contact is replaced with a Micro:
is a simplified perspective view of a headset 510 that includes connector 500 shown in Fig.
47 according to an embodiment of the invention including left and right earbuds 512, 514
connected to connector 500 by a cable 516.

5 [0199] Fig. 50 is a simplified perspective view of a connector plug 520 according to
another embodiment of the invention that is specifically adapted to be used in data
synchronization applications and charging applications. To this end, connector 520 includes
fully functional contacts at the two locations designated for USB data that align with contact
locations 302(5) and 302(6) and the two locations designated for power that align with
contact locations 302(3) and 302(9) as shown in Fig. 52 as well as ground contacts that
connect to connector 520 through its ground ring via the receptacle connector retention clips
as described above. As configured, connector 520 allows for USB 2.0 synchronization as
well as 5 volt, 2 amp charging. Fig. 51 is a simplified perspective view of a USB adapter
cable 530 having a USB male connector 535 at one end and connector 520 shown in Fig. 50
at the other end according to an embodiment of the invention. The two connectors are
connected together by a cable 532.

[0200] Fig. 53 is a simplified perspective view of a connector plug 540 that supports full
audio/video functionality according to another embodiment of the invention including line
out audio, Mikey bus control and a two channel display port as well as USB 2.0
synchronization, 5 volt, 2 amp charging and a 3 volt accessory out signal. Connector 540
includes active circuitry (not shown) within a shell 542 that allows for conversion of display
port video signals to HDMI signals. Connector 540 includes the full complement of twelve
functional contacts as shown in Figs. 34A and 34B. Fig. 54 is a simplified perspective view
of a audio/visual adapter cable 600 having an HDMI connector 602, a USB connector 604
and a digital audio connector 606 at one end connected by a cable 608 to connector 540 at the
other end according to an embodiment of the invention. Active circuitry within shell 542 of
connector 540 separates audio and digital data send over the six display port data contacts of
connector 540 sending the audio signals to both the digital audio connector 606 and HDMI
connector 602 while sending the video signals to HDMI connector 602. The USB data
signals can be passed through the USB contact pins of connector 540 directly to USB
connector 604.
Fig. 55 is a simplified perspective mini display port connector 612 and a USB connector 614 at one end connected by a cable 618 to a plug connector 616 having a pinout as shown in Figs. 34A and 34B at the other end according to another embodiment of the invention. Fig. 56 is a simplified perspective view of a audio/visual adapter cable 620 having a mini display port connector 622 at one end connected by a cable 628 to a high speed data connector 626 at the other end according to another embodiment of the invention. Connector 626 has a pinout that includes two high speed differential data input contacts and two high speed differential data output contacts as shown in Fig. 57 instead of display port contacts. The high speed data contacts allow for data transfer rates of up to 10GB/second thereby allowing 5 GB/sec data transfer using the PCI-express 2.0 standard and 8 GB/sec data transfer using the PCI-express 3.0 standard. Active circuitry embedded in the shell of connector 626 converts the PCI-express signals as necessary to other data formats such as minidisplay port signals.

Fig. 58 is a simplified perspective view of a docking station 630 that includes a connector tab 635 according to an embodiment of the invention that has the same form factor and contact arrangement as tab 44 in Fig. 32. Tab 635 extends upward from a surface 632 upon which a portable electronic device may be placed when docked in station 630 with tab 635 mated with a receptacle connector incorporated into the portable media device. A second surface 634 can support a back of the electronic device while docked.

Docking station 630 allows a portable media device, such as an iPod or MP3 player or an iPhone or other smart phone to be connected to a host computer via connector 635. Connector 635 supports the full complement of twelve contacts set forth in Figs. 34A and 34B and thus allows for line out audio, Mikey bus control and a two channel display port as well as USB 2.0 synchronization, 5 volt, 2 amp charging and a 3 volt accessory out signal. In another embodiment, docking station 630 does not provide full audio/video support and instead provides charging and USB data transfer as well as audio out and legacy/UART (universal asynchronous receiver/transmitter) control. Fig. 59 is a diagram depicting pin locations of connector tab 635 shown in Fig. 58 according to this additional embodiment with reduced contact pins in tab 635.

While the discussion of various particular connectors for accessories, cable adapters or other devices set forth above with respect to Figs. 47-59 specifically included twelve contact connectors having a connector layout compatible with that of plug connector 300
discussed with respect to Figs. 32-34B, eml
other embodiments, similar or identical accessories, cable adapters and other devices may
include connectors having twelve contacts arranged in a different layout than connector 300
or having contacts dedicated to different signals or signals arranged in a different order.
Additionally, still other embodiments include similar or identical accessories, cable adapters
and other devices that include connectors with fewer or more contacts than connector 300. A
person of skill in the art will readily recognize these and other alternative embodiments of the
present invention based on the disclosure herein.

[0205] Embodiments of the invention are suitable for a multiplicity of electronic devices,
including any device that receives or transmits audio, video or data signals among others. In
some instances, embodiments of the invention are particularly well suited for portable
electronic media devices because of their potentially small form factor. As used herein, an
electronic media device includes any device with at least one electronic component that may
be used to present human-perceivable media. Such devices may include, for example,
portable music players (e.g., MP3 devices and Apple's iPod devices), portable video players
(e.g., portable DVD players), cellular telephones (e.g., smart telephones such as Apple's
iPhone devices), video cameras, digital still cameras, projection systems (e.g., holographic
projection systems), gaming systems, PDAs, desktop computers, as well as tablet (e.g.,
Apple's iPad devices), laptop or other mobile computers. Some of these devices may be
configured to provide audio, video or other data or sensory output.

[0206] Fig. 60 is a simplified illustrative block diagram representing an electronic media
device 700 that includes an audio plug receptacle 705 according to embodiments of the
present. Electronic media device 700 may also include, among other components, connecter
receptacle 710, one or more user input components 720, one or more output components 725,
control circuitry 730, graphics circuitry 735, a bus 740, a memory 745, a storage device 750,
communications circuitry 755 and POM (position, orientation or movement sensor) sensors
760. Control circuitry 730 may communicate with the other components of electronic media
device 700 (e.g., via bus 740) to control the operation of electronic media device 700. In
some embodiments, control circuitry 730 may execute instructions stored in a memory 745.
Control circuitry 730 may also be operative to control the performance of electronic media
device 700. Control circuitry 730 may include, for example, a processor, a microcontroller
and a bus (e.g., for sending instructions to the other components of electronic media device
In some embodiments, control circuits receive inputs from input component 720.

Memory 745 may include one or more different types of memory that may be used to perform device functions. For example, memory 745 may include cache, flash memory, ROM, RAM and hybrid types of memory. Memory 745 may also store firmware for the device and its applications (e.g., operating system, user interface functions and processor functions). Storage device 750 may include one or more suitable storage mediums or mechanisms, such as a magnetic hard drive, flash drive, tape drive, optical drive, permanent memory (such as ROM), semi-permanent memory (such as RAM) or cache. Storage device 750 may be used for storing media (e.g., audio and video files), text, pictures, graphics, advertising or any suitable user-specific or global information that may be used by electronic media device 700. Storage device 750 may also store programs or applications that may run on control circuitry 730, may maintain files formatted to be read and edited by one or more of the applications and may store any additional files that may aid the operation of one or more applications (e.g., files with metadata). It should be understood that any of the information stored on storage device 750 may instead be stored in memory 745.

Electronic media device 700 may also include input component 720 and output component 725 for providing a user with the ability to interact with electronic media device 700. For example, input component 720 and output component 725 may provide an interface for a user to interact with an application running on control circuitry 730. Input component 720 may take a variety of forms, such as a keyboard/keypad, trackpad, mouse, click wheel, button, stylus or touch screen. Input component 720 may also include one or more devices for user authentication (e.g., smart card reader, fingerprint reader or iris scanner) as well as an audio input device (e.g., a microphone) or a video input device (e.g., a camera or a web cam) for recording video or still frames. Output component 725 may include any suitable display, such as a liquid crystal display (LCD) or a touch screen display, a projection device, a speaker or any other suitable system for presenting information or media to a user. Output component 725 may be controlled by graphics circuitry 735. Graphics circuitry 735 may include a video card, such as a video card with 2D, 3D or vector graphics capabilities. In some embodiments, output component 725 may also include an audio component that is remotely coupled to electronic media device 700. For example, output component 725 may include a headset, headphones or ear buds that may be coupled to electronic media device 700 with a wire or wirelessly (e.g., Bluetooth headphones or a Bluetooth headset).
Electronic media device 700 may applications) stored on storage device 750 or in memory 745. Control circuitry 730 may be configured to execute instructions of the applications from memory 745. For example, control circuitry 730 may be configured to execute a media player application that causes full-motion video or audio to be presented or displayed on output component 725. Other applications resident on electronic media device 700 may include, for example, a telephony application, a GPS navigator application, a web browser application and a calendar or organizer application. Electronic media device 700 may also execute any suitable operating system, such as a Mac OS, Apple iOS, Linux or Windows and can include a set of applications stored on storage device 750 or memory 745 that is compatible with the particular operating system.

In some embodiments, electronic media device 700 may also include communications circuitry 755 to connect to one or more communications networks. Communications circuitry 755 may be any suitable communications circuitry operative to connect to a communications network and to transmit communications (e.g., voice or data) from electronic media device 700 to other devices within the communications network. Communications circuitry 755 may be operative to interface with the communications network using any suitable communications protocol such as, for example, Wi-Fi (e.g., a 802.11 protocol), Bluetooth, high frequency systems (e.g., 900 MHz, 2.4 GHz and 5.6 GHz communication systems), infrared, GSM, GSM plus EDGE, CDMA, quadband and other cellular protocols, VOIP or any other suitable protocol.

In some embodiments, communications circuitry 755 may be operative to create a communications network using any suitable communications protocol. Communications circuitry 755 may create a short-range communications network using a short-range communications protocol to connect to other devices. For example, communications circuitry 755 may be operative to create a local communications network using the Bluetooth protocol to couple with a Bluetooth headset (or any other Bluetooth device). Communications circuitry 755 may also include a wired or wireless network interface card (NIC) configured to connect to the Internet or any other public or private network. For example, electronic media device 700 may be configured to connect to the Internet via a wireless network, such as a packet radio network, an RF network, a cellular network or any other suitable type of network. Communication circuitry 745 may be used to initiate and
conduct communications with other communications network.

[0212] Electronic media device 700 may also include any other component suitable for performing a communications operation. For example, electronic media device 700 may include a power supply, an antenna, ports or interfaces for coupling to a host device, a secondary input mechanism (e.g., an ON/OFF switch) or any other suitable component.

[0213] Electronic media device 700 may also include POM sensors 760. POM sensors 760 may be used to determine the approximate geographical or physical location of electronic media device 700. As described in more detail below, the location of electronic media device 700 may be derived from any suitable trilateration or triangulation technique, in which case POM sensors 760 may include an RF triangulation detector or sensor or any other location circuitry configured to determine the location of electronic media device 700.

[0214] POM sensors 760 may also include one or more sensors or circuitry for detecting the position orientation or movement of electronic media device 700. Such sensors and circuitry may include, for example, single-axis or multi-axis accelerometers, angular rate or inertial sensors (e.g., optical gyroscopes, vibrating gyroscopes, gas rate gyroscopes or ring gyroscopes), magnetometers (e.g., scalar or vector magnetometers), ambient light sensors, proximity sensors, motion sensor (e.g., a passive infrared (PIR) sensor, active ultrasonic sensor or active microwave sensor) and linear velocity sensors. For example, control circuitry 730 may be configured to read data from one or more of POM sensors 760 in order to determine the location orientation or velocity of electronic media device 700. One or more of POM sensors 760 may be positioned near output component 725 (e.g., above, below or on either side of the display screen of electronic media device 700).

[0215] Fig. 61 depicts an illustrative rendering of one particular electronic media device 780. Device 780 includes a multipurpose button 782 as an input component, a touch screen display 784 as a both an input and output component, and a speaker 785 as an output component, all of which are housed within a device housing 790. Device 780 also includes a primary receptacle connector 786 and an audio plug receptacle 788 within device housing 790. Each of the receptacle connectors 786 and 788 can be positioned within housing 790 such that the cavity of the receptacle connectors into which a corresponding plug connector is inserted is located at an exterior surface of the device housing. In some embodiments, the cavity opens to an exterior side surface of device 780. For simplicity, various internal
components, such as the control circuitry, g
and other components are not shown in Fig. 61. Receptacle connectors according to
embodiments of the invention are particularly suitable to be used as either or both of primary
receptacle 786 or audio plug receptacle 788. Additionally, in some embodiments, electronic
media device 780 has only a single receptacle connector that is used to physically interface
and connect the device (as opposed to a wireless connection) to the other electronic devices.
Embodiments of the invention are also particularly suitable for such a connector.

[0216] As will be understood by those skilled in the art, the present invention may be
embodied in many other specific forms without departing from the essential characteristics
thereof. As an example, while a number of embodiments illustrated above included ground
contacts that were incorporated into the retention features, both in the plug connector as well
as the receptacle connector, other embodiments of the invention may include ground contacts
along portions of the side or tip of the connector that is not part of a retention mechanism.
Similarly, some embodiments may not include any contacts at all on the side of the connector
tab and instead may include both signal and ground contacts on the first and second major
opposing surfaces of the connector tab. In such embodiments, ground contacts can be located
within the contact regions 46a, 46b and/or may be located at one or more locations on major
sides 44a, 44b outside of contact regions 46a, 46b.

[0217] Also, while a number of specific embodiments were disclosed with specific
features, a person of skill in the are will recognize instances where the features of one
embodiment can be combined with the features of another embodiment. For example, some
specific embodiments of the invention set forth above were illustrated with pockets as
retention features. A person of skill in the art will readily appreciate that any of the other
retention features described herein, as well as others not specifically mentioned, may be used
instead of or in addition to the pockets. Also, those skilled in the art will recognize, or be
able to ascertain using no more than routine experimentation, many equivalents to the
specific embodiments of the inventions described herein. Such equivalents are intended to be
encompassed by the following claims.
WHAT IS CLAIMED IS:

1. A plug connector comprising:
   a connector tab having first and second major opposing sides;
   a plurality of electrical contacts carried by the connector tab, the plurality of
   contacts including a first set of contacts formed on the first major side and a second set of
   contacts formed on the second major side, wherein the first plurality of contacts are
   symmetrically spaced with the second plurality of contacts and the connector tab is shaped to
   have 180 degree symmetry so that the connector tab can be inserted and operatively coupled
   to a corresponding receptacle connector in either of two orientations.

2. The plug connector set forth in claim 1 wherein the connector tab
   includes third and fourth opposing sides, each extending between the first and second major
   sides, wherein the third and fourth sides are significantly narrower than the first and second
   sides.

3. The plug connector set forth in claim 2 further comprising ground
   contacts formed on the third and fourth sides.

4. The plug connector set forth in claim 3 further comprising a
   conductive ground ring that at least partially forms the third and fourth sides and wherein the
   ground contacts are part of the ground ring.

5. The plug connector set forth in claim 4 wherein the conductive ground
   ring defines a shape of the connector tab and includes openings on both the first and second
   major surfaces in which the first and second plurality of contacts are respectively formed.

6. The plug connector set forth in claim 5 wherein the conductive ground
   rings includes indentations on the third and fourth sides near a distal end of the connector tab
   that are adapted to operatively engage with a retention mechanism in a corresponding
   receptacle connector during a mating event.

7. The plug connector set forth in claim 6 wherein a cross-section of the
   connector tab taken through the middle of the connector tab along a horizontal plane that does
   not intersect either the first or second major surface of the connector tab has a bread loaf
   shape.
8. The plug connector set forth in claim 1 wherein each of the first and second sets of contacts comprise two contacts.

9. The plug connector set forth in claim 1 wherein each of the first and second sets of contacts comprise four contacts.

10. The plug connector set forth in claim 1 wherein each of the first and second sets of contacts comprise six contacts.

11. The plug connector set forth in claim 1 wherein the first set of contacts comprises a pair of differential data contacts, a power contact and an audio contact and the second set of contacts also comprises a pair of differential data contacts, a power contact and an audio contact.

12. The plug connector set forth in claim 4 further comprising a body from which the connector tab extends and a cable, wherein the body is positioned between the connector tab and the cable and covers an end portion of the conductive ground ring.

13. The plug connector set forth in claim 12 further comprising:

   first and second printed circuit boards, the first printed circuit board (PCB) having a first plurality of contact locations coupled to a first plurality of solder pads by respective electrical traces, the second printed circuit board (PCB) having a second plurality of contact locations coupled to a second plurality of solder pads by respective electrical traces;

   a metal ground plate sandwiched between the first and second circuit boards;

   and

   a plurality of wires bundled within the cable, wherein individual wires in the plurality of wires are soldered to a respective solder pad in either the first or second plurality of solder pads in the base portion of the connector.

14. The plug connector set forth in claim 2 wherein the connector tab is formed with a conductive ground plate sandwiched between first and second dielectric layers and the connector further comprises ground contacts formed on the third and fourth sides that are part of the conductive ground plate.
15. The plug connector set forth in claim 14 wherein the first and second dielectric layers are each printed circuit boards.

16. An electrical connector comprising:

a body;

a connector tab extending longitudinally from the body and including first and second opposing surfaces; and

a plurality of electrical contacts carried by the connector tab, the plurality of contacts including a first set of external contacts formed at the first surface and a second set of external contacts formed at the second surface, wherein the first set of contacts are symmetrically spaced with the second set of contacts and the connector tab is shaped to have 180 degree symmetry.

17. The electrical connector set forth in claim 16 wherein the connector tab includes a side peripheral surface that extends between the first and second opposing surfaces and at least one ground contact formed on the side peripheral surface.

18. The electrical connector set forth in claim 17 wherein the at least one ground contact is formed at the distal tip of the connector tab.

19. The electrical connector set forth in claim 17 wherein the side peripheral surface includes first and second opposing side surfaces and wherein the at least one ground contact includes a first ground contact formed at the first side surface and a second ground contact at the second side surface.

20. The electrical connector set forth in claim 17 wherein the connector tab has a generally rectangular cross section.

21. The electrical connector set forth in claim 20 wherein each of the connector tab’s opposing first and second surfaces has a generally rectangular shape.

22. The electrical connector set forth in claim 20 wherein the first and second connector tab surfaces are at least two times as wide as the first and second side surfaces.
23. The electrical connector set forth in claim 16 wherein the connector tab does not include a polarization key and can be inserted and operatively coupled to a corresponding receptacle connector in either of two orientations.

24. The electrical connector set forth in claim 17 further comprising a metal ground ring that generally defines a shape of the connector tab and includes openings on both the first and second surfaces in which the first and second sets of contacts are respectively formed.

25. The electrical connector set forth in claim 16 wherein the connector tab includes at least one retention feature adapted to engage with a retention feature on a corresponding receptacle connector.

26. The electrical connector set forth in claim 16 wherein the connector tab further includes: (i) first and second opposing side surfaces that extend between the first and second surfaces, and (ii) first and second retention features formed on the first and second side surfaces, respectively.

27. The electrical connector set forth in claim 26 wherein the first and second retention features each comprise pockets.

28. The electrical connector set forth in claim 16 wherein each of the first and second plurality of external contacts consists of two contacts.

29. The electrical connector set forth in claim 28 wherein the connector is an audio connector and the first plurality of external contacts includes a left channel audio contact and the second plurality of external contacts includes a right channel audio contact arranged in a cater cornered relationship with the left channel audio contact.

30. The electrical connector set forth in claim 28 wherein the connector is a data connector and the first plurality of external contacts includes a first set of differential data contacts and the second plurality of external contacts includes a second set of differential data contacts.

31. The electrical connector set forth in claim 16 wherein the first plurality of external contacts includes a first contact and the second plurality of external contacts includes a second contact.
includes a second contact, and wherein the:
contacts arranged in a cater cornered relationship.

32. The electrical connector set forth in claim 16 the first plurality of
external contacts includes a first pair of differential data contacts and the second plurality of
external contacts includes a second pair of differential data contacts, and wherein the first and
second sets of data differential contacts are arranged in a cater cornered relationship with
each other.

33. The electrical connector set forth in claim 16 further comprising a
cable attached to the body, the cable including a plurality of individual insulated wires
corresponding to the plurality of contacts.

34. The electrical connector set forth in claim 19 further comprising a
conductive ground ring that at least partially forms the first and second opposing side
surfaces along with a tip of the connector, and wherein the first and second ground contacts
are part of the conductive ground ring.

35. An electrical plug connector comprising:
a body;
a cable attached to the body;
an unpolarized connector tab extending longitudinally away from the body,
the connector tab having a generally rectangular cross section defined by first and second
major opposing surfaces and first and second opposing side surfaces extending between the
first and second major surfaces;
a plurality of electrical wiping contacts formed on the connector tab, the
plurality of contacts including a first set of external contacts formed at the first major surface
and extending parallel to each other along a length of the connector, and a second set of
external contacts formed at the second major surface and extending parallel to each other
along the length of the connector; and
first and second retention features formed on the first and second side
surfaces, respectively, adapted to engage with retention features on a corresponding
receptacle connector, wherein the first retention feature functions as a first ground contact
and the second retention feature functions as a second ground contact;
wherein the first set of contacts, and the first ground contact is symmetrically spaced with the second ground contact so that the connector tab has 180 degree symmetry and can be inserted and operatively coupled to the corresponding receptacle connector in either of two positions.

36. The electrical connector set forth in claim 35 wherein the plurality of contacts further including a third set of external contacts formed at the first major surface between the first set of external contacts and the body and a fourth set of external contacts formed at the second major surface between the second set of external contacts and the body.

37. The electrical connector set forth in claim 35 further comprising a metal ground ring that generally defines a shape of the connector tab and includes openings at both the first and second major surfaces in which the first and second sets of external contacts are respectively formed.

38. The electrical connector set forth in claim 37 wherein the body includes a thermoplastic shell and a portion of the ground ring extends within the body and is covered by the thermoplastic shell.

39. An electrical receptacle connector comprising:

a housing defining an interior cavity that extends in a direction of the depth of the housing, the cavity having 180 degree symmetry so that a corresponding plug connector can be inserted in the cavity in either of two insertion orientations;

a plurality of electrical contacts positioned within the cavity including a first set of contacts positioned at a first interior surface of the cavity and a second set of contacts positioned at a second interior surface of the cavity spaced apart from the first interior surface, wherein the first and second sets of contacts are mirror images of each other.

40. The electrical connector set forth in claim 25 further comprising at least one retention feature adapted to engage with a retention feature on a corresponding plug connector.

41. The electrical connector set forth in claim 25 further comprising first and second retention features on opposing side surfaces the cavity adapted to engage with retention features on a corresponding plug connector.
42. The electrical connector set forth in claim 25 further comprising an orientation key that can detect which orientation the plug connector is inserted.

43. The electrical connector set forth in claim 25 further comprising circuitry that can detect which orientation the plug connector is inserted.

44. The electrical connector set forth in claim 25 wherein the interior cavity and the plurality of electrical contacts positioned therein are symmetrical with respect to a first plane that horizontally bisects the cavity and with respect to a second plane that vertically bisects the cavity.

45. An electrical connector comprising:
   a body;
   a connector tab extending longitudinally away from the body, the connector tab having a tip at a distal end of the connector, first and second major opposing surfaces and third and fourth opposing side surfaces extending between first and second surfaces;
   a conductive cap covering the tip of the connector and extending from the tip towards the body along at least a portion of the third and fourth side surfaces;
   first and second contact regions located at the first and second major surfaces, respectively, between the third and fourth side surfaces;
   a plurality of electrical contacts carried by the connector tab including a first plurality of electrical contacts positioned within the first contact region and a second plurality of electrical contacts positioned within the second contact region.

46. The electrical connector set forth in claim 45 wherein the cap is a metal cap and the connector further comprising first and second ground contacts formed on sides of the metal cap that extend along the third and fourth side surfaces.

47. The plug connector of claim 45 wherein the metal cap comprises a U-shaped frame.

48. The plug connector of claim 46 wherein the metal cap extends within and is surrounded by the shell.
49. The plug connector of claim 45 wherein the connector tab further comprises retention features formed in the metal cap on each of the third and fourth side surfaces.

50. The plug connector of claim 45 wherein the metal cap has a chamfered portion at that location where the connector tab extends away from the body.

51. The plug connector of claim 45 wherein the body comprises a thermoplastic polymer molded over the base of the connector tab.

52. The plug connector of claim 45 wherein the body further comprises an ABS outer shell formed around the thermoplastic polymer.

53. The plug connector of claim 45 wherein the connector tab has 180 degree symmetry so that it can be inserted into a corresponding connector jack in either of two positions, and wherein individual contacts in each of the first and second sets of contacts are substantially identically spaced within the first and second contact regions, respectively.

54. The plug connector set forth in claim 45 wherein the first and second ground contacts are part of a metal ground ring that defines at least a portion of the first and second minor surfaces surrounding the first and second sets of contacts on at least three sides including a distal end of the connector.

55. The electrical connector set forth in claim 45 wherein the metal cap is part of a metal ground ring that generally defines a shape of the connector tab except for the first and second contact regions in which the first and second sets of contacts are respectively formed.

56. A plug connector comprising:
   a connector base;
   a metal ground ring extending away from and perpendicular to the connector base, the ground ring sized and shaped to define a substantially flat connector tab having first and second major opposing sides along with third and fourth opposing sides extending between and significantly more narrow the first and second major sides, the ground ring having a centrally located opening near a distal end of the connector tab that extends through the first and second major sides;
a plurality of electrical contacts
the ground ring, the plurality of contacts including a first set of contacts formed at the first
major side of the connector tab and a second set of contacts formed at the second major side
of the connector tab; and

dielectric material molded around the plurality of contacts within the centrally
located opening.

57. The plug connector set forth in claim 56 wherein the ground ring
further includes indentations on the third and fourth sides near a distal end of the connector
tab that are adapted to operatively engage with a retention mechanism in a corresponding
receptacle connector during a mating event.

58. A plug connector configured to mate with a receptacle connector along
an insertion axis, the plug connector comprising:
   a flexible member that allows the connector to bend with respect to the
insertion axis; and
   a plurality of contacts carried by the flexible member.

59. The plug connector set forth in claim 58 wherein the flexible member
includes first and second major opposing sides and wherein the plurality of contacts include
at least a first contact formed on the first major side and a second contact formed on the
second major side.

60. The plug connector set forth in claim 59 further comprising a
connector tab portion in which the plurality of contacts are located and a base portion,
wherein the connector tab portion is adapted to be inserted into the receptacle connector and
the flexible member extends along at least a part of a length of the base portion.

61. The plug connector set forth in claim 60 wherein a flexibility of the
connector varies along a length of the connector such that the connector is more flexible in
the base portion of the connector than the connector tab portion.

62. The plug connector set forth in claim 60 wherein the plurality of
contacts includes at least two contacts formed on the first major side and at least two contacts
formed on the second major side.
63. The plug connector set forth in claim 62 wherein the connector has 180 degree symmetry such that it can be inserted into the receptacle connector in either of two orientations.

64. The plug connector set forth in claim 62 further comprising an inner dielectric frame that extends into the connector tab portion, and a U-shaped cap made from a conductive material that surrounds a periphery of the inner dielectric frame at a distal tip of the connector.

65. The plug connector set forth in claim 60 wherein the flexible member comprises a super elastic material.

66. The plug connector set forth in claim 60 wherein the plurality of contacts are formed on a flex circuit and the connector further comprises:

   an inner jacket of flexible dielectric material molded over a portion of the flex circuit;
   a retention clip having an anchor at one end, the retention clip bonded to the U-shaped cap ring such that the anchor extends away from a distal end of the cap; and
   an outer jacket of flexible dielectric material molded around the first jacket, the flex circuit and the retention clip forming a substantially rectangular connector body.

67. A plug connector configured to mate with a corresponding receptacle connector along an insertion axis comprising:

   a body having a base portion and a connector tab extending away from the base portion along the insertion axis, the connector tab having first and second major opposing surfaces along with first and second opposing side surfaces extending between the first and second major surfaces; and
   a plurality of electrical contacts carried by the connector tab, the plurality of contacts including a first set of contacts formed on the first major side of the connector tab and a second set of contacts formed on the second major side of the tab connector;

   wherein at least a portion of the body comprises a flexible material that allows the connector to bend with respect to the insertion axis when the plug connector is inserted into or extracted from the corresponding receptacle connector under a force applied to the plug connector in a direction that intersects the insertion axis.
68. The plug connector set forth in claim 67 wherein the connector portion comprises a flexible member and the plurality of contacts comprise a flexible circuit layered over the flexible member.

69. The plug connector set forth in claim 67 wherein the first and second opposing side surfaces are significantly narrower than the first and second major surfaces.

70. The plug connector set forth in claim 67 wherein the connector comprises four contacts including a left audio contact and a microphone contact formed on the first major surface and a right audio contact formed on the second major surface.

71. The plug connector set forth in claim 67 further comprising a cable attached to the body of the connector, the cable including a plurality of insulated wires corresponding to the plurality of contacts.

72. The plug connector set forth in claim 67 wherein the body has a substantially uniform width and thickness along its entire length.

73. An electronic device comprising:
   a device housing;
   a receptacle connector having a connector housing that defines an interior cavity extending in a direction of the depth of the connector housing and having an opening at a surface of the device housing, the cavity having 180 degree symmetry so that a corresponding plug connector can be inserted in the cavity in either of two insertion orientations;
   a plurality of electrical contacts positioned within the cavity including a first set of contacts positioned at a first interior surface of the cavity and a second set of contacts positioned at a second interior surface of the cavity spaced apart from the first interior surface, wherein the first and second sets of contacts are mirror images of each other; and circuitry operatively coupled to the receptacle connector to, when a plug connector is mated with the receptacle connector, determine which of two orientations the plug connector is positioned and switch individual contacts within the first and second sets of contacts accordingly.
74. The electronic device set forth in claim 73 wherein the receptacle connector further comprises a first retention mechanism that extends into the cavity from a first side surface and a second retention mechanism that extends into the cavity from a second side surface, opposite the first surface, wherein the first and second retention mechanisms are adapted to engage with retention features on sides of the plug connector during a mating event to secure the plug connector in the cavity.

75. The electronic device set forth in claim 74 wherein the first and second retention mechanisms are each coupled to ground and function as ground contacts.

76. The electronic device set forth in claim 75 wherein the first and second retention mechanisms comprise springs biased to extend into the cavity.

77. A method of manufacturing a plug connector having a body and a tab that is adapted to be inserted into a corresponding receptacle connector, the method comprising:

    forming the connector tab to have first and second major opposing surfaces, third and fourth opposing side surfaces extending between the first and second surfaces and a 180 degree symmetrical design such that a plane bisecting a width of the connector tab at an angle perpendicular to the first and second major surfaces divides the tab into left and right portions that have substantially the same outer shape and a horizontal plane bisecting a height of the connector tab at an angle perpendicular to the third and fourth side surfaces divides the tab into upper and lower portions that have substantially the same outer shape;

    forming a first contact region at the first major surface of the connector tab and a second contact region at a second major surface of the connector tab opposite the first major surface, the first and second contact regions being substantially the same size and shape and including an equal number of contacts, wherein contacts in the first contact region are arranged in a first pattern according to a first spacing and contacts in the second contact are also arranged in the first pattern according to the first spacing; and

    attaching a cable having a plurality of insulated wires to the body so that each individual wire in the plurality of insulated wires is electrically connected to a contact in either the first or second contact regions.

78. A method of manufacturing a plug connector comprising constructing a flex circuit having a plurality of flex contacts printed thereon, each of the flex contacts
having a primary contact area and a solder line conductive trace;
attaching contact pucks to each of the flex contacts;
inserting the flex circuit into a conductive ground ring that forms an end of the plug connector;
placing the flex circuit and ground ring into a mold and injecting dielectric material around the flex circuit and contacts pucks and within the ground ring without covering the solder landing area of each contact;
soldering individual wires to the solder landing of each of the plurality of flex contacts;
forming a dielectric jacket around the wires and solder landing area of each contact.

79. The method set forth in claim 77 further comprising attaching an outer shell around the dielectric jacket.

80. A method of manufacturing a plug connector comprising:
attaching a plurality of contact strips to a dielectric contact frame that supports the contact strips;
for each of the contact strips, attaching a contact puck at a first end of the contact strip;
inserting the contact frame into a conductive ground ring that forms an end of the plug connector;
placing the contact frame and ground ring into a mold and injecting dielectric material around the contact frame and contacts pucks and within the ground ring without covering a second end of the contact strips, opposite the first end;
soldering individual wires to the second end of each of the contact strips;
forming a dielectric jacket around the wires and solder landing area of each contact.

81. The method set forth in claim 80 further comprising attaching an outer shell around the dielectric jacket.
