**(54) Title:** DEVICE FOR STORING A LIQUID, PARTICULARLY A DILUTABLE CONCENTRATE, CO-OPERABLE WITH A SPRAY DISPENSER

**(57) Abstract**

The invention relates to a device for storing a liquid, particularly a dilutable concentrate such as a detergent concentrate or the like, said device being co-operable with a spray dispenser bottle (2) and a spray dispenser head which together form a spray dispenser, the device comprising: a top wall (12) and a bottom wall (24), said top wall (12) and bottom wall (24) being separated by one or more side walls, the top and bottom wall (12, 24) each having an opening continuous with a channel (20) running through the device from the top wall opening (14) to the bottom wall opening (22), whereby the top, bottom and sidewalls together with the channel (20), define at least one reservoir area of the device wherein liquid (32) is storable, said device further comprising exit creating means for creating an exit (42) in said device by relative displacement of parts thereof, whereby liquid is releasable from the reservoir area.

DEVICE FOR STORING A LIQUID, PARTICULARLY A DILUTABLE CONCENTRATE, CO-OPERABLE WITH A SPRAY DISPENSER

Field of the invention

5

The present invention relates to a device for storing a liquid, particularly a dilutable concentrate such as a detergent concentrate or the like, which device is co-operable with a spray dispenser bottle and a spray dispenser  
10 head which together form a spray dispenser; to a spray dispenser comprising such a device and to a method for introducing a liquid concentrate, for example, into a spray dispenser bottle.

15 Background of the invention

The use of manually operable spray containers, especially spray bottles, for dispensing reagents such as water, detergent cleaners, de-icers, insecticides and the  
20 like, as an alternative to environmentally harmful aerosols, are well known.

The most spray dispenser bottles currently on the market, are pre-filled with a chemical reagent and sold ready to use.

25 Once the contents of these spray dispenser bottles have been used up, these spray dispenser bottles are often thrown away despite the fact that they mostly remain fully functional.

The US patent 5,529,216 discloses a chemical reservoir  
30 mountable in the neck of a spray bottle dispenser for replenishing the active chemical reagent solution to be sprayed from the spray bottle dispenser. Accordingly, once

the initial solution has been used up, the consumer need only refill the spray bottle with water, whereafter the chemical concentrate carried within the chemical reservoir is opened mixed with the water to provide a use solution.

5 US patent 5,529,216 teaches a reservoir cartridge having a pierceable, metal foil upper wall and pierceable plastic lower wall. The concentrate contained herein, is released into a spray container bottle, by means of a needle member associated with a spray head, which is pushed through  
10 the upper metal foil wall and lower plastic wall of the reservoir cartridge to rupture these, on assembling the spray dispenser, whereby concentrate held therein is released into the spray bottle container through the ruptured lower wall of the cartridge. A disadvantage with this cartridge is that on  
15 piercing the lower wall, concentrate is not released at a sufficiently acceptable rate to provide quickly a use solution.

This needle member doubles as a down-tube for the spray head for transmitting liquid from the spray bottle to the  
20 spray head.

EP-A-0 606 672 discloses a system for diluting and dispensing liquid material including a rigid cartridge containing concentrated liquid, which cartridge is placed in the interior of the upper mouth of a bottle containing water.  
25 Said cartridge is opened at the bottom side thereof by screwing an atomizer onto a threaded mouth piece of the bottle, so that the concentrated liquid present in the rigid cartridge is released into the water. Further cartridge-like devices for use in recharging a chemical reagent solution in  
30 spray dispenser bottles, are known from the US patent 3,655,096 and the German patent document DE 3535986.

A further system for introducing concentrate into a spray dispenser bottle is known from the German patent document DE 19621774.

Another system for introducing concentrate into a spray dispenser bottle is known from the Italian patent document no. 1188018.

Although the devices and systems known from the prior art are functional, they are difficult to make and/or awkward to fill with concentrate, and very often need to be thoroughly cleaned, once filled, in order to be ready for sale.

Furthermore, these types of cartridges often require relatively speaking, a lot of raw material, making them difficult to manufacture. Accordingly, these cartridges are often both with respect to man hours and raw materials expensive to make and fill, making them economically unattractive.

Another problem with known devices and systems is that standard spray containers and/or spray dispenser heads very often need to be modified and/or require extra working features, in order to co-operate therewith. Furthermore such known devices and systems often suffer from leakage.

Under standard spray containers is understood typically containers having a volume of 0.5-1.0 L with a single standard screw neck.

An object of the present invention is to provide a device which substantially overcomes all of these problems.

#### Definition of the invention

30

According to a first aspect, there is provided a device for storing a liquid, particularly a dilutable concentrate

such as a detergent concentrate or the like, said device being co-operable with a spray dispenser bottle and a spray dispenser head which together form a spray dispenser, the device comprising:

- a top wall and
- a bottom wall, said top wall and bottom wall being separated by one or more side walls, the top and bottom wall each having an opening continuous with a channel running through the device from the top wall opening to the bottom wall opening, whereby the top, bottom and sidewalls together with the channel, define at least one reservoir area of the device wherein liquid is storable, said device further comprising exit creating means for creating an exit in said device by relative displacement of parts thereof, whereby liquid is releasable from the reservoir area, wherein:

- (a) the bottom wall is substantially rigid and integral with the bottom wall channel opening and the side walls of the device;

- (b) the bottom wall is rupturable along a juncture with the sidewalls; and

- (c) said rupturable juncture is broken by said relative displacement for creating said exit.

According to another aspect of the present invention, there is provided a spray dispenser assembly comprising a spray dispenser head, a device as described above, and a spray container, the device being mounted between the spray dispenser head and the spray container.

According to yet another aspect of the present invention, there is provided a method of introducing a liquid, particularly a concentrate, into a spray container in order to provide a use solution, said method being further described in claim 11.

**Detailed description of the invention**

The inventors have found that a considerable saving in raw materials is made utilizing a device according to the present invention.

Furthermore, the device according to the present invention is particularly easy to fill in an efficient way with liquid.

Since the device itself comprises the release means for releasing liquid from the reservoir area, this liquid release is easily and efficiently carried out and no additional cooperating features need be associated with either a spray head or spray container to open the device.

Moreover, standard spray bottles require little or no modification in order to co-operate with a device according to the present invention.

The invention will now be further clarified by way of the following specific description with reference to the accompanying drawings, wherein:

figure 1 shows a perspective, exploded view of a first preferred embodiment of an assembly according to the present invention;

figure 2 shows a perspective view of the assembly from figure 1;

figure 3a shows a cut away side view of a first preferred embodiment of a device according to the present invention, when sealed;

figure 3b shows a cut away side view of the device from figure 3a when open; (the embodiment shown in figures 3a and 3b does not form part of the present invention);

figure 4a shows a cut away side view of a second preferred embodiment of the device according to the present invention when sealed;

figure 4b shows a cut away side view of the device from 5 figure 4a when open;

figure 5a shows a cut away side view of a third preferred embodiment of the device according to the present invention when sealed;

figure 5b shows a cut away side view of the device from 10 figure 5a when open; and

figure 6 shows a cut away side view of a fourth preferred embodiment of the device according to the present invention when sealed.

An assembly 1 (figure 1) comprises a spray bottle 15 dispenser 2, a device 4, in the form of a cartridge, and a spray head 6 having a down tube 8 connected thereto.

The cartridge 4 has a lip section 10 protruding outwardly from a top wall 12. The top wall 12 is provided with an opening 14.

20 In use, the cartridge 4 is inserted into a neck section 16 of the bottle 2 (see figure 2) so that the cartridge 4 is suspended by the lip section 10 (see figure 2).

The spray head 6 is subsequently screwed onto the neck section 16 of the bottle, the down tube 8 of the spray head 6 25 extending through a channel (see later) continuous with the top wall opening 14 of the cartridge 4 to terminate in the bottle 2 (see figure 2, figure 3a and 3b).

The cartridge 4 (see figures 3a and 3b), comprises a side wall 18, integral with the lip section 10 and flexible 30 top wall 12.

Top wall opening 14 is continuous with a channel 20 extending through the cartridge 4, which channel 20

terminates in a bottom channel opening 22. As shown in figures 1 and 2, this channel 20 can receive a down tube 8 associated with the spray head.

The side wall 18 and channel 20 define a reservoir area 32, sealed at one end of the device 4 by the flexible top wall 12 and at the other end of the device by a rigid bottom wall 24, extending from the bottom channel opening 22 to the side wall 18.

The bottom wall 24 comprises a first elongated part 26 arranged adjacent to the channel 20, a transverse piece 28 extending from said elongated part 26 to a downwardly extending sealing part 30 arranged adjacent to the side wall 18.

On arranging the assembly as shown in figure 1, the down tube 8 of the spray head 6 is inserted into opening 14 and pushed through the channel 20 (see figures 3A and 3B).

On securing the spray head 6 to the neck section 16 of the bottle 2 by means of an interlocking screw thread 19 on the inside of a depending securing part 34 of the spray head 6, an upper neck section 41 of the down tube 8 presses down into the raised top wall opening 14 of the cartridge 4, whereby the channel 20, integrally connected with the flexible top wall 12, is in turn forced downward, the flexible top wall 12 being inverted downwards by this action, whereby the channel 20 pushes the rigid bottom wall 24 free of the side wall 18 (see figure 3b) in order to create an exit 42 wherethrough concentrate 32 is released to flow into the spray bottle 2 (figure 3b).

Once the spray bottle 2 has been emptied, instead of now disposing of the spray dispenser assembly, the now empty concentrate cartridge 4 can be simply removed, and following

refilling of the spray bottle 2 with water, replaced with a new, fully charged concentrate cartridge 4.

A second preferred embodiment as shown in figures 4a and 4b comprises a side wall 50 having an upper lip 52, an upper opening 54 continuous with a channel 56 which terminates in a lower opening 58. A top wall section 60 extends between the lip 52 and up and over the channel 56, to terminate at the edge channel opening 54. This upper wall section 60 is substantially rigid, having an extended support part 62 arranged adjacent to the channel 56.

At the lower end of the channel 56, a substantially rigid lower wall 64 extends downwardly from the channel 56 to the outer wall 50. The channel 56, the lower wall 64 and the side wall 50 are integral, i.e. they consist of one piece of preferably synthetic material. As with the previous embodiment, the outer wall 50 and the channel 56 define a concentrate reservoir area 66.

The lower wall 64 is more securely attached to the channel 56 than the outer wall 50.

The opening 54 extends in the sealed arrangement of the device (figure 4a) above the upper, outer lip 52.

On arranging a spray dispenser assembly, the upper neck section of a down tube presses down into the opening 54 whereby the channel 56 and upper wall 60 of the cartridge are pushed down with respect to the side wall 50, whereby in turn the seal between the lower wall 64 and the side wall 50 is broken, whereafter the concentrate within the cartridge is released, through opening 69, i.e. on displacement of the channel 56 with respect to the outer wall 50, since the lower wall 64 is more weakly integrally attached to the outer wall 50 than the channel 56, the lower wall 64 ruptures at its juncture with the outer wall 50, due to the rigidity of the

lower wall 64, whereby an opening is created (figure 4b),  
wherethrough concentrate is released into the dispenser.

The further embodiment shown in figures 5a and 5b is  
similar to the embodiment as shown in figures 4a and figure  
5 4b, except that the top wall section 70 has a pushing section  
72 integral therewith, which extends downwardly adjacent to  
the side wall 74 from the top of the cartridge to the bottom  
thereof, in order to contact, at one side, the lower wall 76  
where this is sealed with the side wall 74. Accordingly on  
10 pushing down of the channel, this moves downwardly relative  
to the outer wall, whereby the top wall and accordingly the  
downwardly extending section 72 hereof also move downwardly  
with respect to the outer wall whereby the bottom wall is  
pushed open by the top wall pushing section 72. Concentrate  
15 78 is thereby released through opening 79 (see figure 5b).

A fourth preferred embodiment of the cartridge  
according to the present invention is shown in figure 6.  
Here, the upper wall 80 is substantially T-shaped in cross  
section and comprises a first shoulder section 82 which rests  
20 on the top of the channel 84, said shoulder section 82 is  
continuous with a flat part 86 extending above a lip section  
88 of the cartridge side wall 90 whereby an extended  
depending pushing section 92 depends from under the flat  
section 86 through the reservoir 94 adjacent the side wall 90  
25 to contact the lower wall 96. On forcing down of the flat  
section 86, this comes to rest on the lip section 88, whereby  
the channel 84 and depending section 92 are forced downwards  
with respect to the side wall 90, thereby forming an exit  
between the lower wall 96 and the side wall 90 wherethrough  
30 the concentrate can be released.

As shown in figures 5 and 6, the pushing section has  
the form of cylinder, one end of which has been obliquely cut

off, one side of this pushing section is longer than the other, this side contacting the lower wall 76 in the 'closed' arrangement of the device (see figure 5A, 6).

In the 'open' arrangement of the device (figure 5B),  
5 one side of the device consequently has a larger exit through which concentrate is releasable, since the pushing section at this side does not extend into the exit opening.

The invention is not limited to the above described preferred embodiments, the requested rights are determined by  
10 the following claims.

## Claims

1. Device for storing a liquid, said device being co-operable with a spray dispenser bottle and a spray dispenser head which together form a spray dispenser, the device comprising: a top wall and a bottom wall, said top wall and bottom wall being separated by one or more side walls, the top and bottom wall each having an opening continuous with a channel running through the device from the top wall opening to the bottom wall opening, whereby the top, bottom and sidewalls together with the channel, define at least one reservoir area of the device wherein liquid is storable, said device further comprising exit creating means for creating an exit in said device by relative displacement of parts thereof, whereby liquid is releasable from the reservoir area, wherein:

(a) the bottom wall is substantially rigid and integral with the bottom wall channel opening and the side walls of the device;

(b) the bottom wall is rupturable along a juncture with the sidewalls; and

(c) said rupturable juncture is broken by said relative displacement for creating said exit.

2. Device according to claim 1, being substantially cylindrical in shape and having such dimensions as to fit within a neck portion of a standard spray dispenser bottle.

3. Device according to claims 1 or 2 wherein the channel and the one or more sidewalls are displaceable with respect to one another.

4. Device according to claims 1, 2 or 3, wherein the exit creating means comprise the top wall, said top wall

extending between the top wall opening and the sidewalls, to be displaceable between a first position, wherein the liquid is storable in the reservoir area, and a second position wherein the liquid is releasable from said reservoir area.

5. Device according to any one of claims 1 to 4, wherein the top wall is sealably attached with the top wall channel opening and the sidewalls of the device.

6. Device according to any one of claims 1 to 5, wherein the top wall is integral with the top wall channel opening and the sidewalls and is substantially flexible.

7. Device according to any one of claims 1 to 6, wherein the top wall further comprises a pushing member, which extends from the top wall through the reservoir to contact the bottom wall.

8. Device of any one of claims 1 to 7 wherein the channel protrudes from the top wall when the bottom wall occupies a closed position.

9. Device according to any one of claims 1 to 8 further comprising a lip section which protrudes outwardly over the side walls from the top wall.

10. Assembly comprising said spray dispenser head, a device according to any one of claims 1 to 9 and a spray container.

11. Method of introducing a liquid, into a spray container in order to provide a use solution, comprising the steps of:

- arranging a device according to any of the claims

1-9 in an opening of the spray container,  
- arranging said spray head to fit on the container,  
whereby on removeably securing the spray head onto the  
container, the spray head presses down onto the device so  
that the channel and sidewalls thereof are mutually  
displaced whereby an exit is created in the bottom wall  
of the device whereby liquid stored therein flows out of  
the device and into the container, wherein on mutual  
displacement of the channel and sidewalls, a rupture  
forms along a juncture between the integral channel and  
side walls, which rupture evolves into the exit  
wherethrough liquid flows into the container.
