(54) Title: DUAL LEAF SUSPENSION FOR VEHICLE DRIVE ARRANGEMENT

(57) Abstract: A vehicle drive arrangement for a vehicle of the type having differential power transmission arrangement that converts the rotatory motion of the rotatory power shaft to rotatory motion of first and second drive shafts disposed substantially orthogonal the rotatory power shaft. Primary leaf springs are each coupled at their respective centers to respective drive shafts by pivotal arrangements. The first and second primary springs may include helical springs that are used in place of, or in combination with, the primary leaf springs. Secondary leaf springs may be splayed and therefore need not be arranged parallel to the primary leaf springs. Control over vehicle kinematics is enhanced by configuring the resilience of a fulcrum bumper using resilient, rheological, or active systems. An active system will control vehicle height while stationary to facilitate loading and unloading of the vehicle.

WO 2007/149442 A2

Dual Leaf Suspension for Vehicle Drive Arrangement

Background of the Invention

FIELD OF THE INVENTION

This invention relates generally to suspension systems for vehicles, and more particularly, to a leaf suspension arrangement that is useable with independent and semi-independent suspension systems.

DESCRIPTION OF THE RELATED ART

Leaf spring systems have for many years been used for the suspension of wheeled vehicles. The central element of a leaf spring suspension system for a vehicle is termed a “semi-elliptical” spring configured as an arc-shaped length of spring steel having a rectangular cross-section. At the center of the arc is provided an arrangement for coupling to the axle of the vehicle. At the ends are provided coupler holes for attaching the spring to the vehicle body. For heavy vehicles, leaf springs are stacked on one other to form layers of springs of different lengths. Leaf springs are still used in heavy commercial vehicles and railway carriages. In the case of very heavy vehicles, leaf springs provide the advantage of spreading the load over a larger region of the vehicle's chassis. A coil spring, on the other hand, will transfer the load to a single point.

The well-known Hotchkiss drive, the name of which derives from the French automobile firm of Hotchkiss, employs a solid axle that is coupled at its ends to the centers of respective semi-elliptical leaf springs. There are a number of problems with this form of drive arrangement. First, this drive system is characterized by high unsprung mass.

Additionally, the use of a solid axle results in coupled left/right wheel motion. During heavy cornering and fast acceleration, this known system suffers from vertical deflection and wind-up.

One prior art effort to address the problems associated with the Hotchkiss system
5 employs a parallel leaf spring arrangement at each end of a solid axle. This known arrangement affords increased axle control, in the form of reduced power hop. Other advantages of this known arrangement include roll under steer, auto load leveling and the gross vehicle weight, and no frame changes are required to convert from a Hotchkiss system. However, the known parallel leaf spring arrangement employs a solid axle, and
10 therefore does not provide the benefits of independent suspension. In addition, this known arrangement is plagued with the disadvantage of high unsprung mass.

A de Dion tube vehicle suspension arrangement is a form of semi-independent suspension and constitutes an improvement over the Hotchkiss drive. In this type of suspension, universal joints are employed at the wheel hubs and the differential, and there
15 is additionally provided a solid tubular beam that maintains the opposing wheels in parallel. The de Dion tube is not directly connected to the chassis and is not intended to flex.

The benefits of a de Dion suspension include a reduction in the unsprung weight compared to the Hotchkiss drive. This is achieved by coupling the differential to the chassis. In addition, there are no camber changes during suspension unloading. Since the
20 camber of both wheels is set at zero degrees, the traction from wide tires is improved, and wheel hop under high power operations is reduced compared to an independent suspension. However, the de Dion tube adds unsprung weight.

It is, therefore, an object of this invention to provide a vehicle suspension arrangement that provides the benefits of independent suspension while using leaf spring
25 technology.

It is another object of this invention to provide a vehicle suspension arrangement that employs leaf spring technology and yet affords reduced unsprung mass for reduced inertial effects and improved vehicle handling response.

It is also an object of this invention to provide a vehicle suspension arrangement that
5 employs leaf spring technology and affords reduced suspension inertia.

It is a further object of this invention to provide a vehicle suspension arrangement that employs leaf spring technology and affords reduced noise, vibration, and harshness (NVH).

It is additionally an object of this invention to provide a vehicle suspension
10 arrangement that employs leaf spring technology and affords reduced lateral wheel shake.

It is yet a further object of this invention to provide a vehicle suspension arrangement that employs leaf spring technology and affords reduced side view wind-up at the axle bracket.

It is also another object of this invention to provide a vehicle suspension
15 arrangement that employs leaf spring technology and affords reduced forward and rearward movement.

It is yet an additional object of this invention to provide a vehicle suspension arrangement that employs leaf spring technology and affords a semi-independent suspension effect during asymmetric wheel travel.

It is yet an additional object of this invention to provide a vehicle suspension
20 arrangement that employs leaf spring technology in combination with a coil spring element.

Summary of the Invention

The foregoing and other objects are achieved by this invention which provides a vehicle drive arrangement for a vehicle of the type having a chassis extending
25 longitudinally, and a rotatory power shaft extending longitudinally along the chassis. The rotatory power shaft is coupled at a rearward end thereof to a differential power transmission arrangement that converts the rotatory motion of the rotatory power shaft to

rotatory motion of first and second drive shafts disposed substantially orthogonal the rotatory power shaft. Each of the first and second drive shafts has a respective longitudinal axis. In accordance with the invention, there are provided a differential coupling arrangement for fixedly coupling the differential arrangement to the chassis, and first and second universal coupling arrangements for coupling respective ones of the first and second drive shafts to the differential arrangement, whereby the first and second drive shafts are transaxially displaceable. First and second spring elements are coupled to respective ones of the first and second drive shafts at respective ends distal from the first and second universal coupling arrangements, and to the chassis. In addition, first and second secondary leaf springs are coupled at respective first ends thereof to the first and second drive shafts at respective ends distal from the first and second universal coupling arrangements, and at respective second ends thereof to the chassis. There is additionally provided a beam having first and second ends. The beam is coupled at the first and second ends to respective ones of the first and second drive shafts at respective ends distal from the first and second universal coupling arrangements.

In one embodiment of the invention, each of the first and second ends of the beam are coupled to the first and second drive shafts at a determined transaxial distance.

In a highly advantageous embodiment, the first and second spring elements are respective first and second primary leaf springs. Each of the first and second primary leaf springs is coupled at a respective first end thereof to the chassis and at substantially the center thereof to a respective one of the first and second drive shafts. The first and second secondary leaf springs are arranged, in this embodiment, to be substantially parallel to the respective first and second primary leaf springs.

A beam coupler arrangement is provided for coupling the beam to the chassis. The beam coupler arrangement includes a pivotable beam coupler element pivotally coupled to the beam. A first beam coupler arm is coupled at one end thereof to the pivotable beam coupler element, and at a distal end thereof substantially in the direction of the longitudinal

axis of the first drive shaft, to the chassis. There is additionally provided a second beam coupler arm coupled at one end thereof to the pivotable beam coupler element, and at a distal end thereof substantially in the direction of the longitudinal axis of the second drive shaft, to the chassis.

5 In a practicable embodiment of the invention, the first and second secondary leaf springs are disposed below the respective first and second primary leaf springs. In other embodiments, however, the first and second secondary leaf springs are disposed above the respective first and second primary leaf springs. In some of such other embodiments, the first and second secondary leaf springs are arranged to extend through the chassis

10 In a highly advantageous embodiment of the invention, there are further provided first and second displaceable pivot coupling arrangements for coupling the respective second ends of the first and second secondary leaf springs to the chassis. The displaceable pivot coupling arrangements facilitate adjustment of the effective spring rate of the secondary leaf springs.

15 In other embodiments, there are provided first and second displaceable fulcrum arrangements, also for facilitating the varying of the respective spring rates of the first and second secondary leaf springs.

In accordance with a further aspect of the invention, there is provided a vehicle drive arrangement for a vehicle of the type having a chassis extending longitudinally, and a
20 rotatory power shaft extending longitudinally along the chassis. The rotatory power shaft is coupled at a rearward end thereof to a differential power transmission arrangement that converts the rotatory motion of the rotatory power shaft to rotatory motion of first and second drive shafts disposed substantially orthogonal the rotatory power shaft. Each of the first and second drive shafts has a respective longitudinal axis. In accordance with the
25 invention, there are provided a differential coupling arrangement for fixedly coupling the differential arrangement to the chassis, and first and second universal coupling arrangements for coupling respective ones of the first and second drive shafts to the differential

arrangement, whereby the first and second drive shafts are transaxially displaceable. First and second primary leaf springs are each coupled at respective first and second ends thereof to the chassis and at substantially the center thereof to respective ones of the first and second drive shafts at respective ends of the drive shafts distal from the first and second universal coupling arrangements. In addition, first and second secondary leaf springs are coupled at
5 respective first ends thereof to the first and second drive shafts at respective ends distal from the first and second universal coupling arrangements, and at respective second ends thereof to the chassis. There is additionally provided a beam having first and second ends. The beam is coupled at the first and second ends to respective ones of the first and second drive
10 shafts at respective ends distal from the first and second universal coupling arrangements.

In a highly advantageous embodiment of the invention, there is provided a vehicle suspension arrangement for a vehicle having a chassis and a drive axle. The vehicle suspension arrangement is provided with a primary leaf spring having a substantially longitudinal configuration and first and second ends for coupling to the chassis of the
15 vehicle. A secondary leaf spring has a substantially longitudinal configuration, a first end for coupling to the chassis, and a second end. A coupling element is provided for coupling to the drive axle. In addition, a first pivot joint for pivotally coupling to substantially the center of said primary leaf spring intermediate of its first and second ends for coupling to said coupling element. Finally, a second pivot joint for pivotally coupling the second end
20 of said secondary leaf spring to said coupling element.

In one embodiment, there is further provided a primary leaf coupler for securing said first pivot joint to substantially the center of said primary leaf spring. The first pivot joint is formed of first and second pivot portions, the first pivot portion being fixedly coupled to said primary leaf coupler, and the second pivot portion being fixedly coupled to the coupling
25 element. The first and second pivot portion being configured to be pivotally coupled to each other.

In a still further embodiment, the first pivot joint is configured to enable limited pivotal motion between said primary leaf spring and said coupling element. The pivotal motion in this embodiment therefore is directed longitudinally in see-saw like relation to said primary leaf spring.

5 In accordance with another further apparatus aspect of the invention, there is provided a vehicle suspension arrangement for a vehicle having a chassis and a drive axle. The vehicle suspension arrangement is provided with a primary spring having a substantially helical configuration, the primary spring having a first end for coupling to the chassis of the vehicle, and a second end for coupling to an axle of the vehicle;. A secondary leaf spring
10 that has a substantially longitudinal configuration is further provided. The secondary leaf spring has a first end for coupling to the chassis, and a second end. Additionally, a coupling element couples the second ends of the secondary leaf spring to the drive axle.

In one embodiment of the vehicle suspension arrangement, the coupling element includes a pivot joint for pivotally coupling the second end of said secondary leaf spring to
15 the drive axle.

In a still further embodiment of the invention, there is provided a further primary spring having respective first and second ends thereof coupled to the chassis. The further primary spring is coupled at substantially the center thereof to the drive shaft and to the second end of said primary spring. In a highly advantageous embodiment, the further primary
20 spring is a flat locating plate. The flat locating plate is, in some embodiments, a single plate main leaf spring.

Brief Description of the Drawing

Comprehension of the invention is facilitated by reading the following detailed description, in conjunction with the annexed drawing, in which:

15 Fig. 15 is a simplified schematic representation of the variable position fulcrum bumper of Fig. 14 that is useful to illustrate the variation in vehicle height that is achievable, particularly when the vehicle (not shown) is stationary.

Detailed Description

20 Fig. 1 is a perspective representation of a specific illustrative embodiment of the invention. As shown in this figure, a vehicle suspension system 100 has a chassis that is generally designated as chassis 110. The chassis has a pair of substantially parallel chassis rails 112a and 112b that are coupled to one another by cross-braces 116 and 118.

25 A differential drive arrangement 120 is fixedly coupled to the chassis and converts the rotatory motion of a drive shaft 122 to substantially orthogonal rotatory motion at half shafts 125a and 125b. Each half shaft has an associated pair of universal joints (not specifically designated) that are arranged to be proximal and distal with respect to the differential drive arrangement. Thus, the half shafts, each of which has an associated

longitudinal axis (not shown), accommodate transaxial motion, particularly by operation of the proximal universal joints.

Half shafts 125a and 125b are shown to be coupled at their distal ends to respective leaf springs 130a and 130b. Referring to leaf spring 130a, for example, the leaf spring is, in this specific illustrative embodiment of the invention, pivotally coupled at its forward end to a bracket 132a. At its rearward end, leaf spring 130a is pivotally coupled to a link 134a. As shown in this figure, there is additionally provided a half leaf spring 136a that is also, in this specific illustrative embodiment of the invention, coupled at its forward end to bracket 132a. At its rearward end, half leaf spring 136a is coupled to the distal end of half shaft 125a. Half leaf spring 136a is shown in this specific illustrative embodiment of the invention, to engage a fulcrum 133a.

There is additionally provided a transverse beam 140 that is coupled to cross-brace 116 by a damper 142 and to cross-brace 118 by a further damper 144. Transverse beam 140 has installed thereon a pivoting member 150 to which are attached link elements 152 and 154. The link elements are attached, via brackets (not specifically designated), to cross-brace 118.

Fig. 2 is a side plan view of the embodiment of Fig. 1 of vehicle suspension system 100. Elements of structure that have previously been discussed are similarly designated. As shown in this figure, leaf spring 130a and half leaf spring 136a are each coupled at their respective forward ends to bracket 132a. Leaf spring 130a is pivotally coupled at a pivot 160, and half leaf spring 136a is pivotally coupled at a pivot 162, at bracket 132a. In this specific illustrative embodiment of the invention, pivots 160 and 162 are fixed on bracket 132a, which is fixed in relation to chassis rail 112a. In other embodiments, and as will be described below, there is provided a mechanism (not shown in this figure) that displaces bracket 132a, and in some embodiments, only pivot 162, in relation to chassis rail 112a. Such displacement of the pivots enables advantageous adjustment of the combined spring rate of leaf spring 130a and half leaf spring 136a. Additionally, such displacement is useful

to adjust the height of the vehicle (not shown) while stopped, illustratively to facilitate loading and unloading of cargo and passengers (not shown).

Fig. 3 is a perspective representation of a further specific illustrative embodiment of the invention. Elements of structure that have previously been discussed are similarly designated. As shown in this figure, a vehicle suspension system 170 has a leaf spring 171 and a half leaf spring 172. In contrast to the embodiment of Figs. 1 and 2, leaf spring 171 is arranged to be coupled to the underside of half shaft 125b. Half leaf spring 172 is coupled above half shaft 125b.

Leaf spring 171 is, in this specific illustrative embodiment of the invention, coupled to a bracket 175. Half leaf spring 172 is coupled to chassis rail 177 at a bracket 180. Bracket 180 is shown to be disposed within chassis rail 177. It is particularly noteworthy that in this embodiment half leaf spring 172 is arranged to extend through chassis rail 177 at a fulcrum point 182. The arrangement of this embodiment advantageously reduces the extent to which the leaf suspension system is visible when installed on a vehicle.

Figs. 4a and 4b are respective side plan and partially cross-sectional front plan simplified schematic illustrations of a rotary joint arrangement 200 constructed in accordance with the principles of the invention. Elements of structure that bear analogous correspondence to elements of structure that have previously been discussed are similarly designated in this figure. Referring to Fig. 4a, it is seen that there is provided a leaf spring 130a that, in this specific illustrative embodiment of the invention, is pivotally coupled at its forward and rear ends, as previously described. There is additionally provided a half leaf spring 210 that is also, in this specific illustrative embodiment of the invention, pivotally coupled at a pivot mount 212 at its end distal to a further pivotal mounting 213 at a coupling member 214. The coupling member is itself coupled to axle shaft 215. Half leaf spring 210 is shown in this specific illustrative embodiment of the invention to engage a fulcrum 216.

Fig. 4a further illustrates a pivot link mounting arrangement 220 wherein leaf spring 130a is securely clamped between clamping member 222 and 224, as will be described

below in relation to Fig. 4b. Referring once again to Fig. 4a, clamping member 224 is coupled to a pivot joint 226 that is itself engaged with coupling 214. This arrangement permits a further degree of motion that reduce system internal loading on the pivot joint arrangement and leaf spring elements

5 Fig. 4b is a partially cross-sectional front plan simplified schematic illustrations of rotary joint arrangement 200 constructed in accordance with the principles of the invention. Elements of structure that bear analogous correspondence to elements of structure that have previously been discussed are similarly designated in this figure. It is seen in this figure that leaf spring 130a (shown cross-sectionally) is securely clamped between clamping
10 members 222 and 224 by operation of bolts 230.

Pivot joint 226 is shown in Fig. 4b to be formed of two pivot sections, 214a and 224a. More specifically, pivot section 214a is coupled to coupling 214 (not specifically designated in this figure), and pivot section 224a is coupled to clamping member 224. The pivot sections in this specific illustrative embodiment of the invention, are pivotally engaged
15 in this embodiment of the invention in a hinge-like manner. Therefore, in this embodiment, the pivotal motion is directed longitudinally in see-saw like fashion of leaf spring 130a.

Figs. 5a and 5b are simplified representations of a suspension system 200 constructed in accordance with the principles of the invention (Fig. 5a) and a prior art suspension arrangement 300 (Fig. 5b), illustratively a conventional parallel leaf suspension,
20 both represented in computer-simulated static acceleration conditions. Elements of structure that have previously been discussed are similarly designated in this figure. Figs. 5a and 5b are situated next to one another for sake of facilitating comparison of the effect of acceleration. It is seen that the prior art embodiment of Fig. 5b does not comprise the structural equivalent of half leaf spring 210 shown in Fig. 5a.

25 As can be seen in Fig. 5a, leaf spring 130a remains essentially without distortion during simulated vehicle acceleration as the vehicle (not shown) travels in the direction shown by arrow 201. Prior art suspension arrangement 300, on the other hand, shows

during the simulated vehicle acceleration in the direction of arrow 301a distortion in leaf spring 302 wherein region 313 of leaf spring 302 is distorted downward and region 314 is distorted upward. This condition, which is commonly referred to as “side view windup,” results in the unacceptable condition of power hop during acceleration, as well as a
5 disadvantageous reduction in axle control.

Figs. 6a and 6b are simplified representations of suspension system 200 of Fig. 5a and prior art suspension arrangement 300 of Fig. 5b, both in computer-simulated static braking conditions. Elements of structure that have previously been discussed are similarly designated in this figure. As shown in Fig. 6a, leaf spring 130a remains substantially in its
10 base line configuration during simulated acceleration in the direction of arrow 201. Fig. 6b, on the other hand, shows leaf spring 302 to undergo significant side view windup. Region 313 of leaf spring 302 is distorted upward significantly, while region 314 is distorted downward. When leaf spring 302 is wound up as shown in this simulation, its spring rate is changed significantly, as well as other suspension parameters, resulting in reduced
15 control, particularly when braking is performed on an uneven or bumpy surface (not shown).

Fig. 7 is a simplified schematic representation of a side view of a suspension system 400 constructed in accordance with the principles of the invention with a 1st stage leaf spring 410, and further showing the path of the center of axle 411, as indicated by curved arrow 412 with a fulcrum 414 arranged to communicate with 2nd stage lower leaf spring 416. The
20 embodiment of the invention represented in this figure is pivotally coupled to 1st stage leaf spring 410 at a pivot coupling 414.

Fig. 8 is a simplified schematic representation of a side view of a suspension system 430 constructed in accordance with the principles of the invention. Elements of structure that previously have been discussed are similarly designated in this figure. In this figure,
25 there is illustrated a 1st stage consisting of a coil spring 435, which may, in certain embodiments be a conventional air spring (not shown). In still further embodiments of the invention, coil spring 435 may constitute a combination of a coil spring and an air spring.

Coil spring 435 is substantially equivalent in function to 1st stage leaf spring 410 of the embodiment of Fig. 7. However, as will be noted below, the use of a coil spring results in a variation in the path of the axle.

5 Fulcrum 414 of the 2nd stage lower leaf has been removed, but is nevertheless illustrated in phantom representation to show that its use is optional in this specific illustrative embodiment of the invention. Its use will depend on the geometric needs of the vehicle (not shown).

10 In this embodiment, the path of center of axle 411 is indicated by curved arrow 437. Curved arrow 412, which represents the path of the center axle in the embodiment of Fig. 7, is shown in this figure for comparison purposes.

A significant aspect of this specific illustrative embodiment of the invention is that lower leaf spring 440 is configured as a lower link subcomponent that allows a measure of compliance. It is not a rigid link.

15 Fig. 9 is a simplified schematic representation of a side view of a suspension system 450 constructed in accordance with the principles of the invention with a 1st stage consisting of a substantially equivalent coil spring 455, which in some embodiments of the invention may be an air spring or a combination of a coil spring and an air spring. Coil spring 455 provides vertical load support in place of 1st stage leaf spring 410 shown in Fig. 7. However, in this specific illustrative embodiment of the invention, added control is achieved
20 by the use of an optional single plate main leaf spring 457 as part of the 1st stage with coil spring 455. A lower leaf 460 of the 2nd stage is employed for additional control. In this embodiment, lower leaf 460 permits a measure of compliance and is not a rigid link.

25 Again, Fulcrum 414 of the 2nd stage lower leaf has been removed, but is illustrated in phantom representation to show that its use is optional in this specific illustrative embodiment of the invention. Its use will depend on the geometric needs of the vehicle (not shown).

In this specific illustrative embodiment of the invention, the center of axle 411 travels along a path that conforms to curved arrow 462, as seen in the present side view.

Fig. 10 is a simplified schematic representation of a clip bracket 500 that can be used to push or pull a stack of spring plates 502. Spring plates 502 may be the main spring or the secondary stage in the practice of the invention. In operation, clip bracket 500 is urged upward and downward in the direction of arrows 504 and 506, respectively. Spring plates 502 are contained between rubber bushings 510 and 512, to prevent damage to the spring plates. The operation of clip bracket 500 will be described below in relation to Figs. 11a, 11b, and 11c.

Figs. 11a, 11b, and 11c are simplified schematic side view representations of a height control arrangement 520 constructed in accordance with the principles of the invention that is useful in the loading and unloading of a stationary vehicle, Fig 11a showing a simplified system control arrangement in block and line form. Elements of structure that have previously been discussed are similarly designated in these figures.

As shown in Fig. 11a, a primary leaf spring 130a is coupled at its ends to a chassis rail (not specifically designated) as described in relation to Figs. 1 and 2, above. Leaf spring 130a and secondary spring 502, which may be the equivalent of half leaf spring 136a described above, are coupled to the axle (not specifically designated in this figure). Moreover, although clip bracket 500 is shown in this specific illustrative embodiment of the invention, to operate on the secondary spring system, other embodiments can employ clip bracket 500 on the primary spring, *i.e.*, primary leaf spring 130a. The principle is to provide a way literally push or pull on the spring assembly in a local area to force a temporary camber change. This translates into a change in the height "Z" of the vehicle (see, Fig. 15 and its corresponding description below) that can be selectively employed in response to the operation of a height control system that is generally designated as 530 in the figure.

Height control system 530 includes a height control system 532 that receives vehicle height information from a height sensor 534. A desired vehicle height is entered by a user

(not shown) at user input 536. In a simple embodiment of the invention, user input 536 may constitute a simple pair of switches (not shown) that enable the user to raise or lower the vehicle height as desired. In other embodiments, user input 536 may constitute a programable arrangement (not shown) wherein several vehicle heights and other conditions can be preprogrammed. In response to the data received at user input 536 and the corresponding height data received from height sensor 534, height control system 532 operates an electrical or hydraulic system (not shown) that exerts a force on clip bracket 500 whereby the clip bracket is urged upward or downward, as the case may be, in the direction of arrows 504 and 506, respectively, relative to the chassis rail. In this embodiment of the invention, clip bracket 500 can only exert force on secondary spring 502 statically and must be withdrawn to a baseline condition when the vehicle is in use to prevent damage to the spring. More specifically, the compression surface of the spring should not be loaded during dynamic or fatigue loading, and secondary spring 502 should therefore be employed only statically, such as for loading and unloading the vehicle. For this reason, this specific illustrative embodiment of the invention is provided with a vehicle interface 538 that, among other functions, disables the operation of height control system 532 when vehicle motion is detected.

If the vehicle is lightly loaded, a height sensor 534 provides vehicle height data that indicates that clip bracket 500 must pull on secondary spring 502 such that vehicle trim position is lowered. This allows the vehicle to be loaded more easily by the user. In some embodiments of the invention, when the vehicle is shifted to the "drive" position, vehicle interface 538 instructs height control system 532 to restore the height of the vehicle to a predetermined baseline position to avoid creating a rise in the operational stress applied to secondary spring 502.

Referring to Fig. 11b, it is noted that as the clip bracket (not specifically designated in this figure) is urged upward in the direction of arrow 504, the vehicle height is reduced

from the baseline of Z to Z' , where $Z' < Z$. As the clip bracket urges secondary spring 502 upward, a downward force 542 is applied at the distal end of secondary spring 502.

In Fig. 11c, the clip bracket (not specifically designated in this figure) is urged downward in the direction of arrow 506, the vehicle height is increased from the baseline of Z to Z'' , where $Z'' > Z$. As the clip bracket urges secondary spring 502 upward, an upward force 544 is applied at the distal end of secondary spring 502.

Fig. 12 is a simplified schematic top plan representation of a splayed suspension arrangement 560 constructed in accordance with the invention wherein secondary leaf springs 562a and 562b are shown to be mounted at angles with respect to respective ones of primary leaf springs 130a and 130b. Elements of structure that have previously been discussed are similarly designated in this figure. The secondary leaf springs are not parallel to the respective primary leaf springs, as is the case in the embodiments of Figs. 1 and 2. In a practical embodiment of the invention, angles of deviation for the secondary leaf springs will be on the order of 5° - 10° . Of course, the present invention is not limited to this angular range, which can be determined in response to finite element and kinematic analyses as will be discussed below.

Further in relation to the embodiment of Fig. 12, it is noted that the addition of secondary leaf springs 562a and 562b, which are mounted in the system at an angle relative to primary leaf springs 130a and 130b, enhances axle control, as the present non-parallel arrangement emulates a rigid 4-link rear axle system (not shown). However, a key difference is that in the present system leaf springs 562a and 562b function as springs, not just rigid links. This significant difference allows for compliance that will affect all aspects of the dynamic and kinematic response, including axle wind-up and roll response. The angularly disposed secondary springs of this embodiment of the invention will increase roll stiffness significantly. The resulting stresses that are applied by this arrangement to the mounting plate (not specifically designated) can be balanced on a case-by-case basis using standard analytical systems, such as finite element analysis ("FEA"). Additionally,

kinematic analysis performed using commercially available software, such as the ADAMS software, will on a case-by-case basis identify exact values for the vehicle response to roll inputs. Wheel sideslip and axle steer control are thereby improved.

Fig. 13 is a simplified schematic perspective representation of a variable position fulcrum bumper 570 constructed in accordance with the invention that may be active or passive to rotate in a controlled manner to create a variation in the stiffness of the secondary spring rate. By allowing the fulcrum bumper (whether passive or active) to rotate in a controlled manner about the ground point on the frame bracket, a change in secondary plate stiffness is produced. Essentially, the bumper ground point at chassis rail 112b is rotated such that the point of contact on the secondary spring is moved. The resulting stiffness and kinematic effects are significantly affected. The specific value of the amounts of stiffness and kinematic effects is determined on a case-by-case basis with the use of kinematic modeling. Additionally, the resulting change in spring rate thereby calculated.

In the practice of this aspect of the invention, an electric motor (not shown) is mounted to the frame bracket (not specifically designated) and is actuated to cause the desired rotation after a signal sent from a height transducer identifies how much rotation is needed. A simplified height analysis system is described in relation to Fig. 11a. The displaceable fulcrum bumper herein described can be used in combination with a bumper having a variable stiffness, whereby numerous combinations of final stiffness and kinematic path result. In some embodiments of the invention, variable position fulcrum bumper 570 comprises a rheological material that changes viscosity or stiffness in response to the application of electrical energy. The stiffness of variable position fulcrum bumper 570 is the focus. By activating the fulcrum bumper to become more (or less) rigid, a desired change in supporting spring stiffness is effected and, correspondingly, the geometric and kinematic attributes of the suspension system are affected.

The fulcrum bumper is not limited to be used in combination with a rheological material, and can employ an air spring or other mechanical means to effect the engagement

of the secondary stage leaf. Although in this embodiment of the invention there would be no "active" vehicle retrim, the system could "passively" allow for the rate change, which as a result of the linked kinematic geometry effect, would affect vehicle dynamic behavior in roll, acceleration, braking, or cornering motions. Once vehicle attitude is effected via suspension displacement activity, the secondary plate contact with the fulcrum bumper would initiate reaction forces. A variable rate bumper made of rubber, urethane, or like material that can be voided or otherwise manufactured to cause a nonlinear compression effect that will influence the secondary plate deflection character while under load, albeit to a lesser degree than an active system.

Fig. 14 is a simplified schematic plan representation of the variable position fulcrum bumper of Fig. 13, that has been magnified to facilitate the illustration of certain details of its operation. It is seen in this figure that variable position fulcrum bumper 570 is installed on a carrier 575 that is configured to pivot about a pivot coupling 580 to which is also coupled primary leaf spring 130a. The carrier is coupled to half leaf spring 136a at pivot coupling 582. An electric drive arrangement 590 (shown schematically) is actuatable, illustratively in response to the system described in connection with Fig. 11a, to cause carrier 575 to be rotated about pivot coupling 580 in the direction of arrow 596. Electric drive arrangement 590 is coupled to carrier 575 by a drive coupler 592 that, in this specific illustrative embodiment of the invention, is urged in the directions of two-headed arrow 593. The actuation of the carrier by electric drive arrangement 590 causes variable position fulcrum bumper 570 to change the point at which it communicates with half leaf spring 136a over a range c , whereby half leaf spring 136a is displaced to position 136a', and primary leaf spring 130a is displaced to position 130a'.

Fig. 15 is a simplified schematic representation of the variable position fulcrum bumper of Fig. 14 that is useful to illustrate the variation in vehicle height that is achievable, particularly when the vehicle (not shown) is stationary. Elements of structure that have previously been discussed are similarly designated in this figure. As shown in this figure,

variable position fulcrum bumper 570 causes, as previously noted, half leaf spring 136a is displaced to position 136a'. This displacement is responsive to a displacement of z' at the point identified by line 600. The height displacement of the vehicle corresponds substantially to the displacement z' multiplied by the mechanical advantage nx/x , or n . In a typical vehicle, the value of n may be on the order of 6, and therefore the height of the vehicle will be lowered by approximately $6z'$.

The scope of the claims should not be limited by the preferred embodiments set forth in the examples, but should be given the broadest interpretation consistent with the description as a whole.

CLAIMS:

1. A vehicle drive arrangement for a vehicle of the type having a chassis extending longitudinally, and a rotatory power shaft extending longitudinally along the chassis, the rotatory power shaft being coupled at a rearward end thereof to a differential arrangement for converting the rotatory motion of the rotatory power shaft to rotatory motion of first and second drive shafts disposed orthogonal the rotatory power shaft, each of said first and second drive shafts have a respective longitudinal axis, the vehicle drive arrangement comprising:

a differential coupling arrangement for fixedly coupling the differential arrangement to the chassis;

first and second universal coupling arrangements for coupling respective ones of the first and second drive shafts to the differential arrangement, whereby the first and second drive shafts are transaxially displaceable;

first and second spring elements coupled to respective ones of the first and second drive shafts at respective ends distal from said first and second universal coupling arrangements, and to the chassis;

first and second secondary leaf springs coupled at respective first ends thereof to the first and second drive shafts at respective ends distal from said first and second universal coupling arrangements, and at respective second ends thereof to the chassis; and

a beam having first and second ends, said beam being coupled at the first and second ends to respective ones of the first and second drive shafts at respective ends distal from said first and second universal coupling arrangements,

wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,

wherein said beam coupler arrangement comprises:

a pivotable beam coupler element pivotally coupled to said beam; and

a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the first drive shaft, to the chassis.

2. The vehicle drive arrangement of claim 1, wherein each of the first and second ends of said beam are coupled to the first and second drive shafts at a determined transaxial distance.

3. The vehicle drive arrangement of claim 1, wherein said first and second spring elements are respective first and second primary leaf springs each coupled at respective first ends thereof to the chassis and at the center thereof to respective ones of the first and second drive shafts.

4. The vehicle drive arrangement of claim 3, wherein said first and second secondary leaf springs are arranged to be parallel to said respective first and second primary leaf springs.

5. The vehicle drive arrangement of claim 1, wherein there is further provided a second beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the second drive shaft, to the chassis.

6. The vehicle drive arrangement of claim 4, wherein said first and second secondary leaf springs are disposed below said respective first and second primary leaf springs.

7. The vehicle drive arrangement of claim 4, wherein said first and second secondary leaf springs are disposed above said respective first and second primary leaf springs.

8. The vehicle drive arrangement of claim 7, wherein said first and second secondary leaf springs are arranged to extend through the chassis.

9. The vehicle drive arrangement of claim 1, wherein there are further provided first and second displaceable pivot coupling arrangements for coupling the respective second ends of said first and second secondary leaf springs to the chassis.

10. The vehicle drive arrangement of claim 1, wherein there are further provided first and second displaceable fulcrum arrangements for varying the respective spring rates of said first and second secondary leaf springs.

11. A vehicle drive arrangement for a vehicle of the type having a chassis extending longitudinally, and a rotatory power shaft extending longitudinally along the chassis, the rotatory power shaft being coupled at a rearward end thereof to a differential arrangement for converting the rotatory motion of the rotatory power shaft to rotatory motion of first and second drive shafts disposed orthogonal the rotatory power shaft, each of said first and second drive shafts have a respective longitudinal axis, the vehicle drive arrangement comprising:

a differential coupling arrangement for fixedly coupling the differential arrangement to the chassis;

first and second universal coupling arrangements for coupling respective ones of the first and second drive shafts to the differential arrangement, whereby the first and second drive shafts are transaxially displaceable;

first and second primary leaf springs each coupled at respective first and second ends thereof to the chassis and at the center thereof to respective ones of the first and second drive shafts at respective ends of the drive shafts distal from said first and second universal coupling arrangements;

first and second secondary leaf springs coupled at respective first ends thereof to the first and second drive shafts at respective ends distal from said first and second universal coupling arrangements, and at respective second ends thereof to the chassis; and

a beam having first and second ends, said beam being coupled at the first and second ends to respective ones of the first and second drive shafts at respective ends distal from said first and second universal coupling arrangements,

wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,

wherein said beam coupler arrangement comprises:

a pivotable beam coupler element pivotally coupled to said beam; and

a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the first drive shaft, to the chassis.

12. A vehicle suspension arrangement for a vehicle having a chassis and a drive axle, the vehicle suspension arrangement comprising:

a primary leaf spring having a longitudinal configuration and first and second ends for coupling to the chassis of the vehicle;

a secondary leaf spring having a longitudinal configuration, a first end for coupling to the chassis, and a second end;

a coupling element for coupling to the drive axle;

a first pivot joint for pivotally coupling to the center of said primary leaf spring intermediate of its first and second ends for coupling to said coupling element;

a second pivot joint for pivotally coupling the second end of said secondary leaf spring to said coupling element; and

a beam coupled to the drive axle,

wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,

wherein said beam coupler arrangement comprises:

a pivotable beam coupler element pivotally coupled to said beam; and

a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the drive axle, to the chassis.

13. The vehicle suspension arrangement of claim 12, wherein there is further provided a primary leaf coupler for securing said first pivot joint to the center of said primary leaf spring.

14. The vehicle suspension arrangement of claim 12, wherein said first pivot joint is formed of first and second pivot portions, said first pivot portion being fixedly coupled to said primary leaf coupler, and said second pivot portion being fixedly coupled to said coupling element, said first and second pivot portion being configured to be pivotally coupled to each other.

15. The vehicle suspension arrangement of claim 13, wherein said first pivot joint is configured to enable limited pivotal motion between said primary leaf spring and said coupling element, the pivotal motion being directed longitudinally in see-saw like relation to said primary leaf spring.

16. A vehicle suspension arrangement for a vehicle having a chassis and a drive axle, the vehicle suspension arrangement comprising:

a primary spring having a helical configuration, said primary spring having a first end for coupling to the chassis of the vehicle, and a second end for coupling to an axle of the vehicle;

a secondary leaf spring having a longitudinal configuration, said secondary leaf spring having a first end for coupling to the chassis, and a second end;

a coupling element for coupling the second ends of said secondary leaf spring to the drive axle; and

a beam coupled to the drive axle,

wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,

wherein said beam coupler arrangement comprises:

a pivotable beam coupler element pivotally coupled to said beam; and

a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the drive axle, to the chassis.

17. The vehicle suspension arrangement of claim 16, wherein said coupling element comprises a pivot joint for pivotally coupling the second end of said secondary leaf spring to the drive axle.

18. The vehicle suspension arrangement of claim 16, wherein there is provided a further primary spring having respective first and second ends thereof coupled to the chassis, and being coupled at the center thereof to the drive shaft and to the second end of said primary spring.

19. The vehicle suspension arrangement of claim 18, wherein said further primary spring comprises a flat locating plate.

20. The vehicle suspension arrangement of claim 19, wherein said further primary spring comprises single plate main leaf spring.

21. A vehicle suspension arrangement comprising:
a primary leaf spring having a plan view longitudinal configuration and first and second ends for coupling to the chassis of the vehicle;
a secondary leaf spring having a plan view longitudinal configuration, a first end for coupling to the chassis, and a second end;
wherein the plan view longitudinal configuration of said secondary leaf spring is arranged to be angularly displaced with respect to the plan view longitudinal configuration of said primary leaf spring; and
a beam coupled to a drive axle,
wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,

wherein said beam coupler arrangement comprises:
a pivotable beam coupler element pivotally coupled to said beam; and
a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the drive axle, to the chassis.

22. The vehicle suspension arrangement of claim 21, wherein the plan view longitudinal configuration of said secondary leaf spring and the plan view longitudinal configuration of said primary leaf spring are angularly displaced with respect to each other by an angle of approximately between 5 to 10.

23. The vehicle suspension arrangement of claim 22, wherein the plan view longitudinal configuration of said primary leaf spring is arranged parallel to a chassis frame rail of the vehicle.

24. A vehicle suspension arrangement comprising:
a primary leaf spring having first and second ends for coupling to the chassis of the vehicle;
a secondary leaf spring having a first end for coupling to the chassis, and a second end;
a fulcrum for communicating with one of said primary and secondary leaf springs, said fulcrum being formed of an active material having a configurable resilience characteristic; and
a beam coupled to a drive axle,
wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,
wherein said beam coupler arrangement comprises:
a pivotable beam coupler element pivotally coupled to said beam; and

a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the drive axle, to the chassis.

25. The vehicle suspension arrangement of claim 24, wherein the resilience characteristic of said fulcrum is configurable in response to the application of electrical energy thereto.

26. A vehicle suspension arrangement comprising:
a primary leaf spring having first and second ends for coupling to the chassis of the vehicle;
a secondary leaf spring having a first end for coupling to the chassis of the vehicle, and a second end;
a fulcrum for communicating with one of said primary and secondary leaf springs, said fulcrum being actively displaceable along the one of said primary and secondary leaf springs; and
a beam coupled to a drive axle,
wherein there is further provided a beam coupler arrangement for coupling said beam to the chassis,
wherein said beam coupler arrangement comprises:
a pivotable beam coupler element pivotally coupled to said beam; and
a first beam coupler arm coupled at one end thereof to said pivotable beam coupler element, and at a distal end thereof in the direction of the longitudinal axis of the drive axle, to the chassis.

27. The vehicle suspension arrangement of claim 26, wherein there is further provided an electrical drive arrangement for displacing said fulcrum along the one of said primary and secondary leaf springs.

28. The vehicle suspension arrangement of claim 26, wherein there is further provided an hydraulic drive arrangement for displacing said fulcrum along the one of said primary and secondary leaf springs.

29. The vehicle suspension arrangement of claim 26, wherein there is further provided a fulcrum carrier for supporting said fulcrum, said fulcrum carrier being pivotally coupled to the chassis of the vehicle.

30. The vehicle suspension arrangement of claim 26, wherein the displacement of said fulcrum along the one of said primary and secondary leaf springs produces a corresponding change in the height of the vehicle.

31. The vehicle suspension arrangement of claim 30, wherein the corresponding change in the height of the vehicle is responsive to a vehicle height control system that receives input data from a user input and a vehicle height sensor.
