FIELD

15 Disclosed herein are imidazopyridazine compounds, and pharmaceutical compositions thereof, which modulate Interleukin-17A. Also disclosed herein is the therapeutic use of such compounds, for example, in treating and/or ameliorating an IL-17A mediated inflammatory syndrome, disorder, or disease.

BACKGROUND

20 Interleukin-17 (“IL-17”), also known as IL-17A and CTLA-8, is produced mainly by CD4+ Th17 cells, and also by other immune cells such as CD8+ T cells, $\gamma\delta$ T cells, NK cells, NKT cells, and innate lymphoid cells (ILCs). IL-17A exists as a homodimer (A/A) or as a heterodimer (A/F) with IL-17F and signals through binding to dimeric receptor complex IL-
25 17RA and IL-17RC. IL-17RA is ubiquitously expressed at particularly high levels by haematopoietic cell types, whereas IL-17RC is preferentially expressed by non-haematopoietic cells (Gaffen, S. Structure and signaling in the IL-17 receptor family. Nat. Rev. Immunol. 2009, 9, 556–567). IL-17A/IL-17R signaling induces de novo gene transcription by triggering NF- κ B, C/EBP and MAPK pathways through ACT1–TRAF6–TRAF4. It can also stabilize target mRNA
30 transcripts through the ACT1–TRAF2–TRAF5 complex (Amatya N. *et al.*, Trends in Immunology, 2017, 38, 310-322). IL-17A stimulates the release of inflammatory mediators

including IL-6, IL-8, G-CSF, TNF- α , and IL-1 β that recruit and activate lymphocytes to the site of injury or inflammation and maintain a proinflammatory state.

As discussed below, preclinical and clinical data have demonstrated the significant pathological role of IL-17A in multiple autoimmune and inflammatory diseases.

5 For psoriasis: IL-17A mRNA and/or protein levels are elevated in the lesional skin and blood of patients with psoriasis and correlate with disease severity. IL-17A acts directly in synergy with other cytokines (such as TNF α , IFN γ or IL-22) on keratinocytes triggering a self-amplifying inflammatory response in the skin and leading to the formation of psoriatic plaques. The blockade of IL-17A by means of antibodies to IL-17A or IL-23 results in complete reversal
10 of the molecular and clinical disease features in majority of psoriasis patients, manifesting the significant role of IL-17A and IL-17-producing T-cells in the immunopathogenesis of psoriasis. (Hawkes *et al.*, Psoriasis Pathogenesis and the Development of Novel, Targeted Immune Therapies. J Allergy Clin Immunol. 2017, 140(3): 645–653). The development and approval of IL-17 monoclonal antibodies such as secukinumab, ixekizumab, and brodalumab and their
15 transformational efficacy for psoriasis have demonstrated IL-17A as a valid target for psoriasis treatments. (Blauvelt A. and Chiricozzi A. The Immunologic Role of IL-17 in Psoriasis and Psoriatic Arthritis Pathogenesis. Clin Rev Allergy Immunol. 2018, 55(3):379-390).

For psoriatic arthritis (PsA): IL-17A is mechanistically relevant to PsA through NF κ B activation that triggers transcription of several PsA related genes including the receptor activator
20 of nuclear factor κ B ligand (RANKL). RANKL triggers the differentiation of osteoclast precursor cells into activated osteoclasts, resulting in bone resorption and subsequently joint deformity in PsA (Adamopoulos I. and Mellins E. Nature reviews Rheumatology 2015; 11:189-94). PsA joint is enriched for IL-17+CD8+ T cells, and the levels of this T cell subset are correlated with disease activity (Menon B. *et al.*, Arthritis & Rheumatology 2014; 66: 1272-81).
25 Synovial fibroblasts isolated from PsA patients also contain elevated IL-17R expression and secrete increased IL-6, CXCL8 and MMP3 *ex vivo* compared to osteoarthritis patients. Both secukinumab and ixekizumab are FDA approval drugs for PsA. In matching-adjusted indirect comparison analysis, secukinumab was associated with higher ACR 20/ 50/70 response rates in patients with active PsA than anti-TNF α antibodies (Mease P. *et al.*, Eur. J. Rheumatol. 2019 Jul
30 1;6(3):113-121; Strand V. *et al.*, J. Comp. Eff. Res. 2019, 8(7):497-510; Nash P. *et al.*, Rheumatol. Ther. 2018, 5(1):99-122). In a recent head-to-head study, ixekizumab was superior

to adalimumab in achieving simultaneous improvement of joint and skin disease (ACR50 and PASI100) in patients with PsA and inadequate response to conventional synthetic disease-modifying antirheumatic drug (Mease, P. et al. *Ann Rheum Dis* 2020; 79:123-131). By hitting the same target, IL-17A small molecule inhibitor compounds may exert similar or better efficacy than biologics considering that small molecules generally have better tissue penetration.

For rheumatoid arthritis (RA): IL-17A has been recognized as critical to the progression of rheumatoid arthritis. “The recognition of IL-17 as a pro-inflammatory T cell derived cytokine, and its abundance within rheumatoid joints, provides the strongest candidate mechanism to date through which T cells can capture and localize macrophage effector functions in rheumatoid arthritis” Stamp, L. *et al.*, *Immunol. Cell Biol.* 2004, 82(1): 1-9. Moreover, in rheumatoid arthritis IL-17A acts locally on synoviocytes and osteoblasts contributing to synovitis and joint destruction. Robert and Miossec have proposed the use of synovial biopsies and/or biomarkers to precisely identify patients that would respond to IL-17A inhibition. Their work concludes that IL-17 inhibitors should now be considered in the development of precision medicine in RA. (Robert M. and Miossec P., *Front. Med.*, 2019, 5:364).

For Ankylosing Spondylitis (AS): Various studies have reported elevated IL-17A and Th17 and other cells producing IL-17 in AS blood samples (Wendling D. *et al.*, *Joint Bone Spine.* 2007;74:304–305; Shen H. *et al.*, *Arthritis Rheum.* 2009;60(6):1647–56; Zhang L. *et al.*, *PLoS One.* 2012;7(4):e31000; Jansen D. *et al.*, *Rheumatology (Oxford).* 2015 Apr; 54(4) : 728–735). *In situ* analysis of AS spine has revealed increased IL-17A-producing cells in bone of facet (zygapophyseal) joints (Appel H. *et al.*, *Arthritis Res. Ther.* 2011;13(3):R95). Two advanced IL-17A neutralizing antibodies, secukinumab, approved by FDA for AS, and ixekizumab, have demonstrated efficacy over placebo even in anti-TNF inadequate responders. In contrast, anti-IL-23 p40 and p19 biologics failed to demonstrate beneficial effect (Deodhar A. *et al.*, *Arthritis Rheumatol.* 2019, 71(2):258-270; Baeten D. *et al.*, *Ann. Rheum. Dis.* 2018;77(9):1295–1302), indicating the differential underlying mechanism along IL-23/IL-17 pathway in AS and providing strong evidence to support continuing developing IL-17A inhibitors.

For hidradenitis suppurativa (HS): Increased IL-17 and IL-17-producing T helper cells in the skin lesions of HS patients were reported and molecular proteomics and gene expression data indicate that the IL-23/Th17 pathway is upregulated in HS lesions (Schlapbach C. *et al.*, *J. Am. Acad. Dermatol.* 2011;65(4):790; Kelly G. *et al.*, *British J. Dermatol.* 2015

Dec;173(6):1431-9; Moran B. *et al.*, J. Invest. Dermatol. 2017;137(11):2389; Thomi R. *et al.*, JAMA Dermatol. 2018;154(5):592). Seven of nine (78%) patients with moderate-to-severe HS achieved HiSCR in an open-label pilot-trial with Secukinumab (Prussick L. *et al.*, British J. Dermatol. 2019 Sep;181(3):609-611), and more clinical trials with anti-IL-17 mAbs in HS are on-going.

For bullous pemphigoid (BP): IL-17 is elevated in the blister fluid and perilesional skin of BP patients. (Le Jan S. *et al.*, J. Invest. Dermatol. 2014;134 (12):2908-2917.; Chakievska L. J Autoimmun. 2019, 96:104-112). Exome sequencing of BP patients revealed mutations in twelve IL-17-related genes in one third of patients, providing the genetic link between IL-17 pathway and BP (Chakievska L. J Autoimmun. 2019, 96:104-112). In experimental murine BP, IL-17A-/- mice are protected, and anti-IL-17A treatment significantly reduced skin lesions in wild type (Chakievska L. J Autoimmun. 2019, 96:104-112). Ixekizumab Phase 2 of treatment naive and refractory BP patients is on-going (NCT03099538).

For atopic dermatitis (AD): IL-17 was found to be elevated in peripheral blood and lesions in AD patients and Th17 cells infiltrated more markedly in acute than chronic lesions, suggesting its role in acute phase of AD (Koga C. *et al.*, J. Invest. Dermatol. 2008, 128, 2625–2630). Molecular profile analysis from ustekinumab Phase II suggest likely contribution of IL-23/Th17/IL-17 pathway in AD (Khattri S. *et al.*, Exp. Dermatol. 2017 Jan;26(1):28-35).

For vitiligo: Many studies in vitiligo patients have demonstrated an increased frequency of Th17 cells and higher levels of IL-17 in both circulation and lesions that positively correlates with disease duration, extent, and activity (Singh R. *et al.*, Autoimmun. Rev 2016, Apr;15(4):397-404). Mouse studies demonstrated that depigmentation correlates with greater IL-17 expression/secretion, which modulates vitiligo development (Eby J. *et al.*, Pigment Cell & Melanoma Res. 2014, Nov;27(6):1075-85).

For multiple sclerosis (MS): IL-17 expression is increased in PBMCs, cerebrospinal fluid (CSF) as well as in brain lesions and cells from MS patients (Lock, C. *et al.*, Nat. Med. 2002, 8: 500–508; Matusevicius, D. *et al.*, Mult. Scler. 1999, 5: 101–104; Tzartos, J. *et al.*, Am. J. Pathol. 2008, 172: 146–155). IL-17-producing T cells are enriched in active MS lesions (Tzartos, J. *et al.*, Am. J. Pathol. 2008, 172: 146–155; Willing A. *et al.*, J. Immunol. 2018, 200(3):974-982). IL-17A levels were elevated in the CSF of relapsing-remitting MS (RRMS) patients and correlated with the CSF/serum albumin quotient, a measure of blood-brain barrier

(BBB) dysfunction, together with in vitro data that IL-17A in combination with IL-6 reduced the expression of tight junction -associated genes and disrupted monolayer integrity in a BBB cell line, highlighting the potential importance of targeting IL-17A in preserving BBB integrity in RRMS (Setiadi AF *et al.*, J Neuroimmunol. 2019, 332:147-154). Secukinumab yielded promising first results in a proof-of-concept study in MS patients (Havrdová, E. *et al.*, J. Neurol. 2016, 263: 1287–1295).

For Asthma: IL-17 expression is increased in the lung, sputum, bronchoalveolar lavage fluid, and sera in patients with asthma, and the severity of airway hyperresponsiveness is positively correlated with IL-17 expression levels. (Chakir J. *et al.*, J. Allergy Clin. Immunol. 2003, 111(6):1293-8). IL-17 was reported to be increased in asthmatic airways and induce human bronchial fibroblasts to produce cytokines (Molet S. *et al.*, J. Allergy Clin. Immunol. 2001, 108(3):430-8). Anti-IL-17 antibody modulates airway responsiveness, inflammation, tissue remodeling, and oxidative stress in chronic mouse asthma models (Camargo LdN. *et al.*, Front Immunol. 2018; 8:1835; dos Santos T. *et al.*, Front. Physiol. 2018, 9:1183).

For Chronic Obstructive Pulmonary Disease (COPD): An increase in Th17 cells was observed in patients with COPD compared with current smokers without COPD and healthy subjects, and inverse correlations were found between Th17 cells with lung function (Vargas-Rojas M. *et al.*, Respir. Med. 2011 Nov; 105(11):1648-54). In three recent human COPD studies, gene expression profile in bronchial epithelia showed that higher IL-17 signature expression is associated with a lack of response to inhaled corticosteroid, suggesting that there is a COPD subgroup that may benefit from IL-17 inhibitor therapy (Christenson S. *et al.*, J. Clin. Invest. 2019;129(1):169–181).

For Uveitis: IL-17 promotes the release of inflammatory mediators from retinal pigment epithelium cell line, disrupting the retinal pigment epithelium barrier function (Chen Y. *et al.*, PLoS One. 2011;6:e18139). IL-17 levels were elevated in the serum or aqueous humor of uveitis patients (El-Asrar A. *et al.*, Clin. Immunol. 2011; 139(2):177-84; Jawad S. *et al.*, Ocul. Immunol. Inflamm. 2013; 21(6):434-9; Kuiper J. *et al.*, Am. J. Ophthalmol. 2011;152(2):177-182.). Anti-IL-17 antibody delayed the onset of ocular inflammation and markedly inhibited the development of experimental autoimmune uveitis in rats (Zhang R. *et al.*, Curr. Eye Res. 2009 Apr;34(4):297-303). The analysis of secondary efficacy data from subcutaneous (sc) secukinumab phase 3 trials in uveitis suggested a beneficial effect of secukinumab in reducing

the use of concomitant immunosuppressive medication (Dick A. *et al.*, Ophthalmology 2013; 120(4):777-87). Later study of intravenous secukinumab in uveitis demonstrated greater efficacy than sc dosing, suggesting requiring optimal exposure for efficacy and confirming the therapeutic potential of IL-17A inhibition (Letko E. *et al.*, Ophthalmology 2015, 122(5), 939-948). Ustekinumab that blocks IL-23/IL-17 pathway was also reported to successfully treat a noninfectious uveitis patient who had severe concomitant psoriasis and PsA and failed to respond to conventional immune suppressants (Mugheddu C. *et al.*, Dermatol. Ther. 2017 Sep;30(5);e12527.).

For multiple myeloma (MM): IL-17A serum levels were significantly higher in MM patients and also in patients with advanced stage compared with healthy subjects (Lemancewicz D. *et al.*, Med. Sci. Monit. 2012; 18(1): BR54–BR59). Administration of secukinumab in the SCIDhu model of human myeloma weekly for 4 weeks after the first detection of tumor in mice led to a significant inhibition of tumor growth and reduced bone damage compared to isotype control mice (Prabhala R. *et al.*, Leukemia. 2016 February; 30(2): 379–389).

For systemic lupus erythematosus (SLE): Increased serum or plasma levels of IL-17, expansion of IL-17-producing T cells in the peripheral blood, and infiltration of Th17 cells in target organs like the kidneys was observed in SLE patients (Wong C. *et al.*, Lupus. 2000;9(8):589–593; Wong C. *et al.*, Clinical Immunology. 2008;127(3):385–393; Zhao X-F. *et al.*, Mol. Biol. Rep. 2010 Jan;37(1):81-5; Chen X. *et al.*, J. Clin. Immunol. 2010 Mar;30(2):221-5; Xing Q. *et al.*, Rheumatol. Int. 2012 Apr; 32(4):949-58). Imbalance between Th17 cells and regulatory T (Treg) cells has been observed in SLE patients including quiescent stage (Ma J. *et al.*, Clin. Rheumatol. 2010;29(11):1251–1258; Dolff S. *et al.*, Clin. Immunol. 2011, 141(2):197-204). Overexpression of IL-17A using adenovirus enhanced the severity of lupus nephritis, while blockade of IL-17A using neutralizing antibody resulted in decreased severity of lupus nephritis (Wen, Z. *et al.*, PLoS One. 2013, 8: e58161). In a phase 2 study, ustekinumab, an anti-IL-12/23 p40 monoclonal antibody blocking IL-23/IL-17 pathway, has demonstrated efficacy in SLE patients (van Vollenhoven R. *et al.*, Lancet 2018; 392: 1330–39). Human expression studies, animal models, and clinical trials indicate that IL-17 blockade may become a promising therapeutic strategy for SLE (Koga T. *et al.*, Expert Rev. Clin. Immunol. 2019, 15 (6) 629-637).

In summary, animal and human studies have shown that IL-17A plays crucial role in pathogenesis of the multiple diseases and/or conditions discussed above. The significance of

targeting IL-17A has been demonstrated by the transformational efficacy of injectable IL-17A neutralizing antibodies in patients

Despite the advances achieved with injectable IL-17A antagonist antibodies, there is a long-felt need for the development of an oral small molecule IL-17A inhibitor as it may broaden treatment options for many patients without access to biologics. In addition, a safe and efficacious small molecule IL-17A inhibitor may offer significant benefits to patients over the injectable IL-17A neutralizing antibodies such as convenient dosing regimens and cost savings, which in turn may provide effective long-term disease management.

However, the development of an oral small molecule treatment has remained challenging. For example, no oral small molecule IL-17A inhibitor has progressed into late-stage clinical trials yet, and only two oral small molecule IL-17A inhibitors have progressed into phase I clinical trials (NCT04586920 and NCT04883333) as of September 28, 2021. Additionally, as of December 2021, one of these clinical trials (NCT04586920) was suspended due to safety review. Accordingly, there is a need for new small molecule IL-17A modulators (e.g., inhibitors).

As used herein, the term “QD” means once daily.

As used herein, the term “BID” means twice daily.

The term “alkyl” is a straight or branched saturated hydrocarbon. For example, an alkyl group can have 1 to 12 carbon atoms (i.e., (C₁-C₁₂)alkyl) or 1 to 6 carbon atoms (i.e., (C₁-C₆)alkyl). Examples of alkyl groups include, but are not limited to, methyl (Me, -CH₃), ethyl (Et, -CH₂CH₃), 1-propyl (*n*-Pr, *n*-propyl, -CH₂CH₂CH₃), isopropyl (*i*-Pr, *i*-propyl, -CH(CH₃)₂), 1-butyl (*n*-bu, *n*-butyl, -CH₂CH₂CH₂CH₃), 2-butyl (*s*-bu, *s*-butyl, -CH(CH₃)CH₂CH₃), *tert*-butyl (*t*-bu, *t*-butyl, -CH(CH₃)₃), 1-pentyl (*n*-pentyl, -CH₂CH₂CH₂CH₂CH₃), 2-pentyl (-CH(CH₃)CH₂CH₂CH₃), neopentyl (-CH₂C(CH₃)₃), 1-hexyl (-CH₂CH₂CH₂CH₂CH₂CH₃), 2-hexyl (-CH(CH₃)CH₂CH₂CH₂CH₃), heptyl (-CH₂)₆CH₃, octyl (-CH₂)₇CH₃, 2,2,4-trimethylpentyl (-CH₂C(CH₃)₂CH₂CH(CH₃)₂), nonyl (-CH₂)₈CH₃, decyl (-CH₂)₉CH₃, undecyl (-CH₂)₁₀CH₃, and dodecyl (-CH₂)₁₁CH₃. Any alkyl group may be unsubstituted or substituted.

The term “C_(a-b)” (where *a* and *b* are integers referring to a designated number of carbon atoms) refers to an alkyl, alkenyl, alkynyl, alkoxy or cycloalkyl radical or to the alkyl portion of a radical in which alkyl appears as the prefix root containing from *a* to *b* carbon atoms inclusive. For example, C₍₁₋₄₎ denotes a radical containing 1, 2, 3 or 4 carbon atoms.

The term “cycloalkyl” refers to a saturated or partially unsaturated all carbon ring system having 3 to 8 carbon atoms (i.e., C₍₃₋₈₎cycloalkyl), and preferably 3 to 6 carbon atoms (i.e., C₍₃₋₆₎cycloalkyl), wherein the cycloalkyl ring system has a single ring or multiple rings in a

spirocyclic or bicyclic form. Exemplary cycloalkyls include, but are not limited to, cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl, and cyclooctyl. Unless otherwise stated specifically in the specification, a cycloalkyl group may be unsubstituted or substituted. Some cycloalkyl groups may exist as spirocycloalkyls, wherein two cycloalkyl rings are fused through a single carbon atom; for example and without limitation, an example of a spirocyclopentyl group is

10 Unless otherwise stated specifically in the specification, a spirocycloalkyl group may be unsubstituted or substituted. Bicyclic cycloalkyl ring systems also

The term “heteroaryl” refers to a single aromatic ring that has at least one atom other than carbon in the ring, wherein the atom is selected from the group consisting of oxygen, nitrogen and sulfur. Exemplary heteroaryl ring systems include but are not limited to pyridinyl, pyrimidinyl, pyrazinyl, pyridazinyl, pyrimidinyl, pyrazolyl, oxazolyl, oxadiazolyl, isoxazolyl, triazolyl, imidazolyl, tetrazolyl, thienyl, thiazolyl, isothiazolyl, thiadiazolyl, or furyl.

20 The term “halogen” or “halo” refers to bromo (-Br), chloro (-Cl), fluoro (-F) or iodo (-I).

Where the compounds disclosed herein have at least one stereocenter, they may accordingly exist as enantiomers or diastereomers. It is to be understood that all such isomers and mixtures thereof are encompassed within the scope of the present invention.

“Diastereoisomers” are stereoisomers that have at least two asymmetric atoms, but which are not mirror images of each other.

“Enantiomers” are a pair of stereoisomers that are non-superimposable mirror images of each other. A “racemic” mixture is a 1:1 mixture of a pair of enantiomers. A “scalemic” mixture of enantiomers is mixture of enantiomers at a ratio other than 1:1.

Where the processes for the preparation of the compounds according to the invention give rise to mixture of stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. The compounds may be prepared in racemic form, a scalemic mixture, or individual enantiomers may be prepared either by enantiospecific synthesis or by resolution. The compounds may, for example, be resolved into their component enantiomers by standard techniques, such as the formation of diastereomeric pairs by salt formation with an optically active acid, such as (-)-di-*p*-toluoyl-D-tartaric acid and/or (+)-di-*p*-toluoyl-L-tartaric acid followed by fractional crystallization and regeneration of the free base. The compounds may also be resolved by formation of diastereomeric esters or amides, followed by chromatographic separation and removal of the chiral auxiliary. Alternatively, the compounds may be resolved using a chiral column via HPLC or SFC. In some instances rotamers of compounds may exist which are observable by ¹H NMR leading to complex multiplets and peak integration in the ¹H NMR spectrum.

The absolute stereochemistry is specified according to the Cahn-Ingold-Prelog R-S system. Chiral centers, of which the absolute configurations are known, are labelled by prefixes *R* and *S*, assigned by the standard sequence-rule procedure, and preceded when necessary by the appropriate locants (*Pure & Appl. Chem.* 45, 1976, 11–30). Certain examples contain chemical structures that are depicted or labelled as an (*R**) or (*S**). When (*R**) or (*S**) is used in the name of a compound or in the chemical representation of the compound, it is intended to convey that the compound is a pure single isomer at that stereocenter; however, absolute configuration of that stereocenter has not been established. Thus, a compound designated as (*R**) refers to a compound that is a pure single isomer at that stereocenter with an absolute configuration of either (*R*) or (*S*), and a compound designated as (*S**) refers to a compound that is a pure single isomer at that stereocenter with an absolute configuration of either (*R*) or (*S*). For example, 4-cyclopropyl-*N*-((1*S*)-(7-(((3*aR**)-5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-

yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1,2,5-oxadiazole-3-carboxamide:

, refers to a compound that is either:

5 Pseudoasymmetric stereogenic centers are treated in the same way as chiral centers, but are given lower-case symbols, *r* or *s* (*Angew. Chem. Int. Ed. Engl.* **1982**, 21, 567–583).

During any of the processes for preparation of the compounds disclosed herein, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those
10 described in Protective Groups in Organic Chemistry, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

Furthermore, it is intended that within the scope of the present invention, any element, in
15 particular when mentioned in relation to a compound of the disclosure, or pharmaceutically acceptable salt thereof, shall comprise all isotopes and isotopic mixtures of said element, either naturally occurring or synthetically produced, either with natural abundance or in an isotopically enriched form. For example, a reference to hydrogen includes within its scope ^1H , ^2H (*i.e.*, deuterium or D), and ^3H (*i.e.*, tritium or T). In some embodiments, the compounds described
20 herein include a ^2H (*i.e.*, deuterium) isotope. By way of example, the group denoted $-\text{C}_{(1-6)}\text{alkyl}$ includes not only $-\text{CH}_3$, but also $-\text{CD}_3$; not only $-\text{CH}_2\text{CH}_3$, but also $-\text{CD}_2\text{CD}_3$, *etc.* Similarly,

references to carbon and oxygen include within their scope respectively ^{12}C , ^{13}C and ^{14}C and ^{15}O and ^{16}O and ^{17}O and ^{18}O . The isotopes may be radioactive or non-radioactive. Radiolabelled compounds of the disclosure may include a radioactive isotope selected from the group comprising ^3H , ^{11}C , ^{18}F , ^{35}S , ^{122}I , ^{123}I , ^{125}I , ^{131}I , ^{75}Br , ^{76}Br , ^{77}Br and ^{82}Br . Preferably, the radioactive isotope is selected from the group of ^3H , ^{11}C and ^{18}F .

Scheme 1

Compounds of formula **I** can be prepared as shown in **Scheme 1**. Aldehydes **A-I** can undergo reductive amination with diamines **C-Ia**. Aldehydes **A-I** can be treated with diamines **C-Ia**, such as ethylene diamine, and a reducing agent such as NaCNBH₃ in a solvent such as methanol in the presence of additives such as acetic acid. The resulting adducts (structures not shown) are treated with a reagent such as triphosgene or CDI in a solvent such as DCM or THF to afford the corresponding cyclic ureas **A-II**. Alternatively, Boc protected diamines **C-Ib**, such as *tert*-butyl (*S*)-(1-aminopropan-2-yl)carbamate, can undergo reductive amination using the conditions listed above. In a second step, cyclization of the resulting reductive amination

20

adducts (structure not shown) to the urea using reagents such as potassium *tert*-pentoide in solvents such as *tert*-amyl alcohol affords the corresponding ureas **A-II**. Compounds **A-II** can be treated with an acid such as TFA in a solvent such as DCM to afford compounds **A-III**. These conditions are herein known as “Boc deprotection conditions”. Amide bond formation between amines **A-III** and carboxylic acids (R^4CO_2H) can be achieved through the use of a coupling agent, such as HATU or EDCI, in the presence of a base, such as DIPEA, in a solvent, such as DMF, MeCN, or DCM, with or without an additive, such as HOBt and DIPEA, to yield compounds **I**. Alternatively, amide bond formation can be achieved by treatment of amines **A-III** with a reagent such as a carboxylic acid chloride (R^4CO_2Cl) in the presence of additives such as DIPEA or DMAP in solvents such as DCM or THF to yield compounds of formula **I**. In addition, amines **A-III** can be treated with *N*-hydroxysuccinate esters in the presence of reagents such as DIPEA in a solvent such as acetonitrile to provide compounds of formula **I**. These conditions are herein known as “amide bond formation conditions”.

15 Scheme 2

Compounds **Ia** may be prepared as shown in **Scheme 2**. Cyclocondensation of aminopyridazines **B-I** with iodoketones **C-II** in a solvent such as DMA in the presence of 4 Å molecular sieves

affords compounds **B-II**. Hydrogenation using palladium catalysis in the presence of hydrogen gas and ammonium hydroxide in ethanol, or in the presence of hydrogen gas and acetic acid in a solvent such as THF then yields compounds **B-III**. Deprotection of compound **B-III** using “Boc deprotection conditions” and subsequent amide bond formation using amide bond formation conditions yields compounds **Ia**.

Scheme 3

10 Compounds **D-VII** can be prepared as shown in **Scheme 3**. Compounds **D-I** can be converted to compounds **D-II** by a two-step process with initial treatment with a reagent mixture capable of transferring a vinyl group, such as potassium trifluoro(vinyl)borate, in the presence of a catalyst, such as $\text{Pd}(\text{dtbpf})\text{Cl}_2$. The second step of this process is oxidative cleavage of the vinyl

substituent using reagents, such as sodium periodate, in the presence of a catalyst, such as potassium osmate, in a solvent, such as aqueous 1,4-dioxane. Subsequent condensation of compounds **D-II** with (*S*)-(-)-2-methyl-2-propanesulfinamide gives the corresponding sulfinimide, that upon addition of nucleophilic carbon-containing reagents, such as alkyl

magnesium halides, alkyl lithiums or metalated alkyl nitriles, yields sulfinamides **D-III**. Conversion of compounds **D-III** to **D-IV** can be accomplished by treatment with an acid such as aqueous hydrochloric acid. Compounds **D-IV** are converted to compounds **D-V** by treatment with compounds such as **D-VIII** in the presence of a base such as DIPEA or TEA in a solvent such as ACN, DCM or THF. Alternatively, compounds **D-IV** can be converted to compounds **D-V** by reductive amination using a catalyst such as tetraethoxytitanium with a reducing agent such as NaCNBH₃, in a solvent such as MeOH with an aldehyde such as CbzNH(C)(R^{1a})_mCHO. Compounds **D-V** are converted to compounds **D-VI** by treating with H₂ in the presence of a palladium catalyst such as Pd/C in a solvent such as methanol. Compounds **D-VI** can be converted to compounds **D-VII** by treating with a reagent such as triphosgene or CDI in a solvent such as DCM or THF. Compounds **D-VII** can be converted to compounds **Ia** as shown in **Scheme 2** employing methods analogous to those describing the conversion of compounds **B-III** to compounds **Ia**.

Scheme 4

Compounds **D-VIa** can be prepared as shown in **Scheme 4**. Compounds **D-Ia** can be converted to compounds **D-IX** by treatment with **D-XI**, in the presence of a catalyst, such as RuPhos Pd G3, with an additive such as K₃PO₄ and in a solvent such as aqueous 1,4-dioxane. Compounds

D-IX can be converted to compounds **D-X** by treatment with potassium osmate and sodium periodate, in a solvent, such as aqueous 1,4-dioxane. Conversion of compounds **D-X** to compounds **D-VIa** can be accomplished by titanium isopropoxide-mediated imine formation with diamines **C-Ia** followed by reduction with a reducing agent such as NaCNBH₃ in a solvent such as methanol in the presence of an additive such as acetic acid. Compounds **D-VIa** can be converted to compounds such as **D-VII** as shown in **Scheme 3**.

Scheme 5

Compounds **B-III** may also be prepared as shown in **Scheme 5**. Protection of the amine in aminochloropyridazine **E-I** with a protecting group such as 2,2-dimethylpropanamide followed by metalation, formylation and treatment of the resulting aldehyde (structure not shown) with (*S*)-(-)-2-methyl-2-propanesulfinamide provides compound **E-II**. Compound **E-II** can be converted to compounds **E-III** by a four-step procedure as shown above. Compounds **E-III** can be converted to compounds **E-IV** by sulfoxamine deprotection using reagents such as HCl in solvents such as EtOAc, phthalimide formation as shown above and amine deprotection using reagents such as sulfuric acid in solvents such as 1,4-dioxane or MeOH. Treatment of

compounds **E-IV** with compounds **C-II** using a base such as Na_2HPO_4 in a solvent such as NMP followed by phthalimide removal using reagents such as hydrazine in solvents such as EtOH provides imidazopyridazines **E-V**. Compounds **E-V** are converted to compounds **B-III** by a three-step process shown above. Initial treatment of compounds **E-V** with compounds **D-VIII** in a solvent such as ACN with a base such as DIPEA provides an intermediate (structure not shown). Then, chlorine hydrogenolysis of this intermediate with reagents such as ammonium formate and TFE in the presence of a palladium catalyst such as Pd/C in a solvent such as ethanol followed by cyclization using reagents such as triphosgene or CDI provides compounds **B-III**.

Scheme 6

Compounds **F-V** can be prepared as shown in **Scheme 6**. Treatment of amino alcohols **F-I** with 4-nitrobenzenesulfonyl chloride in the presence of a base such as DIPEA in a solvent such as DCM provides compounds **F-II**. Treatment of compounds **F-II** with a base, such as DIPEA, in a solvent, such as THF, provides aziridines **F-III**. Reaction of aziridines **F-III** with amines **D-IVa** provides compounds **F-IV**. Deprotection of the protecting / activating group can be accomplished by treatment with reagents such as thiophenol with a base such as K_2CO_3 in a solvent such as ACN, thereby providing diamines **F-V**.

Scheme 7

Compounds **G-IV** can be prepared as shown in **Scheme 7**. Treatment of aldehydes **A-I** with a reducing agent such as sodium borohydride in a solvent such as MeOH affords the corresponding alcohols **G-I**. Compounds **G-I** can be converted to compounds **G-II** by a two-step process comprising deprotection of compounds **G-I** using “Boc deprotection conditions” and subsequent amide bond formation using “amide bond formation” conditions with either $\text{R}^4\text{CO}_2\text{H}$ or $\text{R}^4\text{CO}_2\text{Cl}$. Treatment of alcohols **G-II** with reagents such as carbon tetrabromide in solvents such as DCM with additives such as 1*H*-imidazole affords compounds **G-III**. Reaction of compounds **G-III** with diamines **C-Ib** using reagents such as carbonic acid dicesium in solvents such as ACN or DCM provides compounds **G-IV**. Compounds **G-IV** can then be elaborated into compounds of formula **Ia** as described in the schemes above.

Scheme 8

Compounds **B-I** may also be prepared as shown in **Scheme 8**. Aminopyridazines **H-I** can be prepared by protection of amines **E-IV** as the 2,2-dimethylpropanamide. Treatment of aminopyridazines **H-I** with reagents such as hydrazine in solvents such as EtOH affords amines **H-II**. Reaction of compounds **H-II** with oxathiazolidine dioxides **H-VI** using a base such as DIPEA or TEA in solvents such as ACN provides diamines **H-III**. Iodine (23.8 g, 93.7 mmol) was then added portion-wise and the mixture was allowed to warm to rt and stirred for 24 h at which time it was quenched with saturated aqueous NaHCO₃ and stirred for 15 min. The organic layer was removed and washed sequentially with half-saturated aqueous NaHCO₃ and brine, dried over anhydrous MgSO₄, filtered, and concentrated to a residue. To the residue was added chilled hexanes (50 mL), and the mixture was stirred vigorously for 10 min during which time a white precipitated formed. The white solid was removed by filtration through a pad of silica and the solids were washed with a second portion of chilled hexanes. To a suspension of trimethylsulfoxonium chloride (0.581 g, 4.52 mmol) in THF (7 mL) was added a solution of *t*-BuOK (4.24 mL, 4.24 mmol, 1 M in THF) and the resulting solution was allowed to stir for 2 h. Separately, (*S*)-2-((*tert*-

5 butoxycarbonyl)amino)-6,6,6-trifluoro-5,5-dimethylhexanoic acid (885 mg, 2.83 mmol, Step E) in THF (7 mL) was cooled to 0 °C, CDI (550 mg, 3.39 mmol) was subsequently added and the resulting mixture was stirred for 2 h at 0 °C. The resulting mixture was stirred for another 2 h at 25 °C. The reaction mixture was then poured into saturated aqueous NaHCO₃, the pH of the reaction mixture was adjusted to pH 11 by the addition of 3 M aqueous NaOH and then the resulting solution was extracted with DCM (40 mL x 3). The combined organic extracts were washed with brine (2 x 30 mL), dried over anhydrous Na₂SO₄, filtered, and concentrated to dryness under reduced pressure to provide the title compound as a yellow foam, which was used without further purification.

Step B: *tert*-Butyl ((1*S*)-(7-((5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)carbamate. *tert*-Butyl ((1*S*)-(7-(((2-((*tert*-butoxycarbonyl)amino)-4,4-difluorocyclopentyl)amino)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)carbamate (138.3 mg, 0.225 mmol, Step A) and THF (1.5 mL) were added to a reaction vial. To the vial was then added potassium *tert*-pentoxide (0.51 mL, 1.01 mmol, 2 M in THF) and the reaction mixture was stirred at 50 °C for 1 h. The reaction mixture was then poured into saturated aqueous NaHCO₃ and extracted with EtOAc (3 x 20 mL). The combined organic layers were washed with 0.1 M aqueous HCl and brine, dried over anhydrous Na₂SO₄, filtered, and concentrated to dryness to afford a yellow oil. This oil was purified by silica gel chromatography (0 – 100% EtOAc (with 10% MeOH) in hexanes) to afford the title compound (37% yield over two steps) as a yellow foam.

Step C: 1-((2-((*S*)-Amino(4,4-difluorocyclohexyl)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methyl)-5,5-difluorohexahydrocyclopenta[*d*]imidazol-2(1*H*)-one. To a vial containing *tert*-butyl ((1*S*)-(7-((5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)carbamate (44.9 mg, 0.083 mmol, Step B) was added TFA (0.5 mL) and the reaction mixture was allowed to stir at rt for 1 h. The reaction mixture was then concentrated under reduced pressure to remove any residual TFA and then diluted with saturated aqueous NaHCO₃ and allowed to stir for 5 min. The aqueous layer was then extracted with EtOAc (3 x 20 mL). The combined organic layers were washed with brine, dried over anhydrous Na₂SO₄, filtered, and concentrated to afford the title compound (87% yield) as a yellow foam, which was used without further purification.

Step D: 4-Cyclopropyl-*N*-((1*S*)-(7-((5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1,2,5-oxadiazole-3-carboxamide. A reaction vial was charged with 4-cyclopropyl-1,2,5-oxadiazole-3-carboxylic acid (22.3 mg, 0.145 mmol), EtOAc (0.36 mL), T₃P (0.078 mL, 0.13 mmol, 50% w/v solution in EtOAc), and DIPEA (0.05 mL, 0.29 mmol) and the reaction mixture was allowed to stir at rt for 5 min. A solution of 1-((2-((*S*)-amino(4,4-difluorocyclohexyl)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methyl)-5,5-difluorohexahydrocyclopenta[*d*]imidazol-2(1*H*)-one (31.9 mg, 0.073 mmol, Step C) in DCM (2 mL) was then added to the reaction mixture and the resulting reaction mixture was allowed to stir at rt for 17 h. The reaction mixture was then concentrated to remove solvent, dissolved in minimal MeOH, and applied directly to acidic reverse phase HPLC purification (Waters XSelect CSH C18, 5 μm, 19 x 100 mm; 25 – 60% H₂O (with 0.16% TFA) in MeCN (with 0.16% TFA)) to afford the title compound (25% yield) as a white powder after lyophilization.

Step E: 4-Cyclopropyl-*N*-((*S*)-(7-(((3*aR**,6*aS**)-5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1,2,5-oxadiazole-3-carboxamide. 4-Cyclopropyl-*N*-((1*S*)-(7-((5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-yl)methyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1,2,5-oxadiazole-3-carboxamide (10.6 mg, Step D) was purified by chiral SFC (Chiralpak IC3 5 μm, 250 x 21 mm, Mobile phase: 25% methanol, 75% CO₂) to afford two diastereomers. The first eluting diastereomer was 4-cyclopropyl-*N*-((*S*)-(7-(((3*aR**,6*aS**)-5,5-difluoro-2-oxohexahydrocyclopenta[*d*]imidazol-1(2*H*)-

Step A: *tert*-Butyl (*S*)-((4,4-difluorocyclohexyl)(7-(hydroxymethyl)imidazo[1,2-*b*]pyridazin-2-yl)methyl)carbamate. A solution of *tert*-butyl (*S*)-((4,4-difluorocyclohexyl)(7-formylimidazo[1,2-*b*]pyridazin-2-yl)methyl)carbamate (800 mg, 2.03 mmol) in MeOH (7 mL) was cooled to 0 °C and then sodium borohydride (194 mg, 5.07 mmol) was added. The resulting mixture was stirred for 30 min while it warmed to rt. The reaction mixture was quenched with water (8 mL) and the aqueous layer was extracted with EtOAc (3 x 20 mL). The combined organic layers were washed with brine, dried over anhydrous Na₂SO₄, filtered, and concentrated to dryness to give a yellow-white powder. The solid was purified by silica gel chromatography (10-100% EtOAc (10% MeOH) / hexanes) to afford the title compound (81% yield) as a white powder.

Step B: (*S*)-(2-(Amino(4,4-difluorocyclohexyl)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methanol. A solution of *tert*-butyl (*S*)-((4,4-difluorocyclohexyl)(7-(hydroxymethyl)imidazo[1,2-*b*]pyridazin-2-yl)methyl)carbamate (450 mg, 1.14 mmol, Step A) in DCM (11 mL) was cooled to 0 °C and TFA was added dropwise. The resulting mixture was stirred for 3.5 h while the ice bath warmed to rt. The reaction mixture was concentrated to dryness and then dissolved in saturated aqueous NaHCO₃. The pH of the mixture was adjusted to pH 11 by the addition of sodium carbonate and then it was extracted with DCM:IPA (4:1, 5 x 25 mL). The combined organic layers were washed with brine, dried over anhydrous Na₂SO₄, filtered and concentrated to dryness. Purification by preparative HPLC (X-Bridge Prep C18 5 μm, 50 x 250 mm, 5-100% acetonitrile / water (with 20 mM NH₄OH)) afforded the title compound (86% yield).

Step C: (*S*)-(2-((4,4-Difluorocyclohexyl)(1-isopropyl-1*H*-pyrazole-5-carboxamido)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methyl 1-isopropyl-1*H*-pyrazole-5-carboxylate. To a solution of (*S*)-(2-(amino(4,4-difluorocyclohexyl)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methanol (232 mg, 0.78 mmol, Step B) in MeCN (4 mL) was added DIPEA (0.337 mL, 1.96 mmol). The resulting mixture was stirred at rt for 5 min and then 2,5-dioxopyrrolidin-1-yl 1-isopropyl-1*H*-pyrazole-5-carboxylate (236 mg, 0.94 mmol, Intermediate 7) was added. The reaction mixture was stirred at rt for 40 min, concentrated to dryness and the title compound was used without further purification.

Step D: (*S*)-*N*-((4,4-Difluorocyclohexyl)(7-(hydroxymethyl)imidazo[1,2-*b*]pyridazin-2-yl)methyl)-1-isopropyl-1*H*-pyrazole-5-carboxamide. To (*S*)-(2-((4,4-difluorocyclohexyl)(1-isopropyl-1*H*-pyrazole-5-carboxamido)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methyl 1-isopropyl-1*H*-pyrazole-5-carboxylate (454 mg, 0.80 mmol, Step C) were added NaOH (128 mg, 3.19 mmol), THF (2 mL) and water (1 mL) sequentially. The resulting mixture was heated at 45 °C for 18 h. Then, additional NaOH (64 mg, 1.60 mmol) was added and the mixture was heated for 1 h at 45 °C. After that time, additional water (3 mL) and THF (1.5 mL) were added and the mixture was heated at 45 °C for 3.5 h. The reaction was quenched by the addition of 2 M aqueous HCl (1.5 mL) and then the organic solvent was removed *in vacuo*. The remaining aqueous layer was extracted with DCM:IPA (4:1, 5 x 5 mL). The combined organic layers were dried over anhydrous Na₂SO₄, filtered, and concentrated to dryness. The residue was purified by silica gel chromatography (10-100% (10% MeOH in EtOAc) / hexanes) to afford the title compound (54% yield).

Step E: (*S*)-*N*-((7-(Bromomethyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1-isopropyl-1*H*-pyrazole-5-carboxamide. The resulting mixture was cooled to 0 °C and carbon tetrabromide (186 mg, 0.56 mmol) was added. The reaction mixture was stirred for 30 min while the ice bath was allowed to warm to rt. The reaction was cooled to 0 °C and additional polymer-bound triphenylphosphine (156 mg, 0.47 mmol), 1*H*-imidazole (32.1 mg, 0.47 mmol), and carbon tetrabromide (155 mg, 0.47 mmol) were added. The resulting mixture was stirred for 40 min while the ice bath was allowed to warm to rt.

The reaction mixture was filtered, the solids rinsed with DCM, and the filtrate concentrated to dryness. The residue was purified by silica gel chromatography (0-100% EtOAc / hexanes) to afford the title compound (21% yield).

Step F: *tert*-Butyl (*S*)-(1-(((2-((4,4-difluorocyclohexyl)(1-isopropyl-1*H*-pyrazole-5-carboxamido)methyl)imidazo[1,2-*b*]pyridazin-7-yl)methyl)amino)methyl)-3,3-difluorocyclobutyl)carbamate. To a solution of (*S*)-*N*-((7-(bromomethyl)imidazo[1,2-*b*]pyridazin-2-yl)(4,4-difluorocyclohexyl)methyl)-1-isopropyl-1*H*-pyrazole-5-carboxamide (48 mg, 0.10 mmol, Step E) in DCM (2 mL) were added carbonic acid dicesium (63.1 mg, 0.194 mmol) and *tert*-butyl (1-(aminomethyl)-3,3-difluorocyclobutyl)carbamate (27.5 mg, 0.116 mmol) and the resulting mixture was stirred at rt for 3 h. To the mixture was added DIPEA (0.05 mL, 0.291 mmol) and then the mixture was concentrated to dryness. The residue was dissolved in MeCN (2 mL) and a few drops of DMF were added. The resulting mixture was stirred at rt for 18 h. The reaction mixture was then partitioned between water and DCM and the organic layer was washed with saturated aqueous NH₄Cl. The aqueous layer was extracted with DCM (3 x 25 mL), and the combined organic layers were dried over anhydrous Na₂SO₄, filtered, and concentrated to dryness. The residue was purified initially by silica gel chromatography (0-100% EtOAc (10% MeOH) / hexanes) and then further purified by silica gel chromatography (40-100% EtOAc (10% MeOH) / hexanes) to afford the title compound (84% yield).

IN VITRO BIOLOGICAL DATA

IL-17A(FLAG-tagged): IL-17RA(His-tagged) binding disruption Eu-HTRF assay

An antibody directed against the FLAG tag of IL-17A (SEQ ID NO:1) is labeled with the HTRF donor chromophore (Europium-cryptate). IL-17A is present as a dimer that is “locked into” this quaternary structure due to the formation of loop-spanning intramolecular disulfide bridges. The construct of IL-17RA used in the assay excludes the outer-membrane portion of the receptor and is fused to a C-terminal 10xHis tag (SEQ ID NO:2). An antibody directed against the His tag of the IL-17RA chimera is labeled with the HTRF acceptor chromophore (“D2”). The fluorescence-resonance energy transfer (FRET) depends on the vicinity of the donor chromophore to the acceptor, and interruption of the binding between the IL-17A and IL-17RA causes the reduction/loss of FRET. Therefore, this assay allows to evaluate the compound effect on the binding IL-17A and IL-17RA by monitoring the fluorescence intensity of donor vs acceptor. The assay was run using either Protocol 1 or Protocol 2 described below.

Protocol 1: 40 nL of 2-fold serial diluted compound solution for total 22 dilution points is added into each well of a 1536-well, white, low-volume, non-binding plate (Greiner #782904), then 2 µl of FLAG tagged IL-17A at 2x final concentration (2.5 nM) in solution of PBS+ 0.01% Triton-X100 is added to each well. The assay plate is briefly centrifuged then incubated for 1 h at rt. A mixed solution is prepared containing 2x 5nM 10HISxIL-17RA, 2x 2.5nM Eu-anti-FLAG (CISBIO), 2x 5nM D2-anti-HIS (CISBIO) in PBS + 0.01% Triton-X100 + 200 mM Potassium Fluoride (Sigma 60238) and 2 µl of mix is added to each well of the assay plate. The plate is briefly centrifuged then incubated for 2 h at rt. The HTRF intensities at the wavelength of donor (620 nm) and acceptor (665 nm) are measured using BMG Pherastar. The ratio between intensities at two wavelengths is calculated and plotted against the compound concentration and the data is fitted to a one-site competition model to yield IC₅₀ of the compound.

Protocol 2. 40 nl of 2-fold serial diluted compound solution for total 22 dilution points is added into each well of a 1536-well, white, low-volume, non-binding plate (Greiner #782904), then 2 µl of FLAG tagged IL-17A at 2x final concentration (1 nM) in solution of PBS+ 0.01% Triton-X100 is added to each well. The assay plate is briefly centrifuged then incubated for 1 h at rt. A mixed solution is prepared containing 2x 5nM 10HISxIL-17RA, 2x 2.5nM Eu-anti-FLAG (CISBIO), 2x 5nM D2-anti-HIS (CISBIO) in PBS + 0.01% Triton-X100 + 200 mM Potassium Fluoride (Sigma 60238) and 2 µl of mix is added to each well of the assay plate. The plate is briefly centrifuged then incubated for 2 h at rt. The HTRF intensities at the wavelength of donor (615 nm) and acceptor (665 nm) are measured using BMG Pherastar. The ratio between intensities at two

wavelengths is calculated and plotted against the compound concentration and the data is fitted to a one-site competition model to yield IC₅₀ of the compound.

IL-17A acts directly on keratinocytes through binding to dimeric receptor IL-17RA/RC and drives the production of a number of inflammatory mediators known to be elevated in psoriasis
lesional tissue. IL-17A small molecule inhibitors that block the IL-17A to interact with IL-17R
would inhibit the IL-17A signaling in its targeted cells such as keratinocytes. The compound
functional activity is evaluated for its impact on IL-17A-induced G-CSF production in human
normal keratinocyte (NHK).

NHK assay

Adult normal human keratinocytes are cultured in keratinocyte growth medium (Lonza) in a flask till reaching ~ 90% confluence, then cells are transferred to a 384-well plate at density of 3000-4000 cell/well. Recombinant human IL-17A (Gibco PHC9174) is pre-incubated with titrated compound or DMSO for 1 h at rt then added to the cell culture plate. The final
concentration of IL-17A is 5 ng/mL and DMSO is 0.2%, in the culture containing 5% FBS. Cells
are cultured/treated for 24 h at 37 °C. Supernatants are collected and G-CSF production is
measured through HTRF technology using Human G-CSF Kit (CisBio). G-CSF concentration was
extrapolated from the standard curve and IC₅₀ is determined using GraphPad Prism. Cell viability
is also evaluated using CellTiter-Glo kit (Promega) and effect of compound on cell viability is
compared to DMSO control.

In cases where the compound was tested more than once, the IC₅₀ value shown is a simple average of the measured values.

A: IC₅₀ < 4 μm; B: 4 μm ≤ IC₅₀ ≤ 10 μm; C: IC₅₀ > 10 μm
