(63) Continuation-in-part of application No. 10/943,771, filed on Sep. 16, 2004.

ABSTRACT

A controlled access device produces a controlled access layer in a packet switching environment. The device includes a game monitoring system, a plurality of Ethernet ports, an internal switch, and an encoding mechanism. The game monitoring system monitors and manages game accounting data. The plurality of Ethernet ports facilitate data ingress and egress, and are connectable to a distribution switch. The internal switch forwards transmitted data packets from one or more ingress ports to an egress port. The encoding mechanism encodes a first type of data packets with a QoS high packet delivery priority, and encodes a second type of data packets with a QoS lower packet delivery priority.
CONTROLLED ACCESS LAYER SYSTEM AND METHOD

RELATED APPLICATIONS

[0001] This application is a continuation-in-part of U.S. patent application Ser. No. 10/943,771 filed Sep. 16, 2004, entitled System And Method For Gaming-Content Configuration And Management System, now pending, which is hereby incorporated herein by reference.

The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent disclosure, as it appears in the Patent and Trademark Office patent files or records, but otherwise reserves all copyright rights whatsoever.

FIELD OF THE INVENTION

[0003] This invention relates generally to a system and method for utilizing a controlled access device to produce a controlled access layer in a packet switching environment, and more particularly, to a system and method for utilizing a controlled access device that encodes specific types of data for high priority packet delivery in a controlled access layer of a packet switching environment.

BACKGROUND OF THE INVENTION

[0004] Today’s slot machines have parameters programmed into their code such as theme, percentage, denomination, lines bet, minimum bet, maximum bet, game runtime, and the like. Changing any of these parameters requires new game code, regulatory approval for the code changes, physical movement of machines weighing hundreds of pounds and regulatory approval for the move and oversight.

[0005] Past methods of changing games on the floor have been manual in nature. As stated above, games and their associated gaming parameters are typically programmed into EPROMs (Erasable Programmable Read-Only Memory) contained within the gaming machines. Accordingly, the changing of games (or modifying gaming parameters) requires the EPROMs to be changed. Such a procedure involves physically opening the gaming machines, erasing and reprogramming the code (EPROM), and re-sealing the EPROM if required by the regulatory jurisdiction. This also requires the entire game to be ‘re-optioned’ which is a long, error-prone manual process.

[0006] Furthermore, gaming machines have operated for the most part as stand-alone devices, at least with respect to non-progressive gaming. In this regard, while there may have existed some limited forms of communication or networking, fully-networked data and communication systems have not been traditionally implemented. One reason for this lack of fully-networked infrastructure is the difficulty in upgrading system infrastructure, due to the constant utilization of a gaming system, 24 hours a day, 7 days a week, 365 days a year. For this reason and others, gaming machines have typically been utilized as separate machines, which are swapped out or upgraded, but which generally operate autonomously. It would be desirable for gaming machines instead, to be utilized as components of a larger interactive and symphonic organizational arrangement. However, many obstacles have made such an arrangement difficult and unwieldy to visualize, let alone implement.

[0007] However, the lack of such a system deprives casino owners of both apparent and actual control over their gaming floors. Further, casino patrons are limited in the variety and selection of both games, and the gaming parameters within such games, that are available to them. These limitations are commonly due to the particularized nature and general lack of customization typically associated with individual gaming machines. In this regard, casino owners have become aware that by adding additional features to gaming machines, they may be able to maintain a player’s attention to the gaming machines for longer periods of time. This, in turn, leads to the player wagering at the gaming machine for longer periods of time, thereby increasing casino profits.

[0008] One technique that has been employed to maintain a player’s attention at the gaming machine has been to provide players with access to gambling-related information. Moreover, it would be desirable to provide the player with interactive access to the above information. This type of interactivity would allow players significantly more flexibility to make use of the above-described information. The gambling-related information could also be utilized by the player in a much more efficient manner. In this regard, greater levels of flexibility and access are likely to make a player remain and gamble at the gaming machine for significantly longer periods of time. Unfortunately, the system components that are currently utilized for displaying and accessing this type of information, such as external keypads and display modules, are extremely limited in the functionality and capabilities that they provide, thus limiting the success of their ability to maintain a player’s attention.

[0009] As technology advances in the casino gaming environments, the network architecture is moving towards high-speed Ethernet networks (or other standard broadband protocol) that replace the previous serial networks and proprietary data acquisition systems. Often, the network architecture in these Ethernet gaming networks has a very controlled access layer environment. In this regard, sometimes the network architecture utilizes a layered network topology.

[0010] The first or top layer is typically referred to as the core layer, which is the backbone of the system. In this layer there are usually very robust and high-speed switches in a data center environment. These switches can process packets very rapidly. Preferably, only decisions relating to packet destination and packet transmission are made in the core layer.

[0011] The next layer, which connects to the core layer, is typically referred to as the distribution layer. The primary job of the distribution layer is aggregation and routing. Often this layer raises the network frames at OSI (Open System Interconnect) layer 2 to routable packets at OSI layer 3.

[0012] The base layer is typically referred to as the access layer. The access layer is the starting point for most traffic on the network. The access or workgroup layer connects users and devices. Important functions of the access layer include shared bandwidth, switched bandwidth, MAC-layer (Media
Access Control layer) filtering, and micro segmentation. A MAC address refers to a hardware address that uniquely identifies a node of a network. The access layer is designed to pass traffic to the network for valid network users and to filter traffic that is passed along through the network. Typically, the access layer is the point at which end users are connected to the network. Additionally, the access layer provides the means to connect to the devices located in the distribution layer, as well as providing connections to both local and remote devices. Security and policy decisions are also made at the access layer since the access layer is the entry point to the network.

The prior data acquisition systems have typically been based on a proprietary network that utilized a serial protocol standard. While the data rates of such prior systems were relatively slow (7.2 kbps in comparison to even the slowest Ethernet speeds (10 Mbs)), these prior networks were single-use networks with the sole purpose of communicating the SDS (Slot Data Systems) information (or other similar game accounting information) to and from the floor.

An Ethernet network, having significantly more bandwidth, would typically be utilized as a shared network where the SDS (or other similar game accounting protocols) is only an application that runs on the network along with other applications and servers. Instead of controlling a proprietary network, a prior casino network might even be integrated into an existing casino Ethernet network.

Typically, the prior serial networks did not support many new technologies such as iView devices (i.e., player tracking user interface devices), System Gaming, and game downloads. Additional technologies are also likely to follow once more bandwidth is made available. While these new technologies, many of which are bandwidth-intensive, there is a growing need to ensure that SDS data (or other similar game accounting data) maintains precedence and consistently arrives at the SDS server without losing data.

One relevant LAN (local-area network) technology is known as Quality of Service (QoS). This technology allows the network to place certain packets at a higher priority than other packets to ensure timely delivery. Normally, networks are “best effort” delivery. QoS adds in the ability to prioritize certain packets for a better and more controlled delivery. Typically, QoS is used to ensure timely delivery of data in applications such as a Voice over IP network (VoIP). Instead of the “first-in-first-out,” best effort delivery of many shared networks, QoS ensures timely delivery of data with virtually no packet loss. Similarly, in the casino environment, game accounting data also requires that data packets are delivered in a timely fashion with no packet loss.

Referring again to VoIP, since VoIP data (and now streaming video, video conferencing, and the like) is very sensitive to network delay, under QoS the VoIP packets are given a priority that places the VoIP packets into a high priority queue. The high priority queue is serviced until empty while other less sensitive data waits in another lower priority queue or queues. Since technologies like VoIP are industry standards, most switches recognize them and supply a QoS designation to ensure that VoIP packets take precedence in any communication stream.

Referring again to an access layer of a layered network, it is beneficial to make policy decisions at the access layer because this is usually the “ingress level.” The ingress level is the point in the system where packets enter the network. Accordingly, this is a timely point at which to examine the packets and make policy decisions based on the packet information.

Typically, there are two ways to prioritize data packets using QoS. Using one technique, a QoS aware access switch uses the port location on the switch to indicate in which port the high priority is located. However, in this scenario, there is nothing to stop personnel from either accidently or intentionally moving the plug to a different port location, thus giving whatever is plugged into the high priority port the highest priority, and giving the intended high priority data the lower priority. This could possibly lead to packet loss of the intended high priority data.

Another technique to supply the QoS information uses a non-controlled device but encodes the QoS code into the IP packets of the intended high priority data. This technique provides the right encoding, but is required to be performed in a Controlled Access environment. The problem with using a non-controlled device stems from the potential for a third party to program their game (or other device) to download packets with a high priority QoS code, thus making this game compete for bandwidth with the intended high priority data. Even if the access switch has the capabilities to filter and change the QoS information, this functionality is typically related to the port location, and thus, involves the same problems noted above. While some high-end switches offer a QoS filter for MAC addresses (the internal address of the Ethernet port), this type of filtering presents significant problems and is difficult to administer.

Accordingly, there exists a continuing need for a system or method for non-industry standard IP communication to be labeled for high quality delivery. The preferred embodiments of the system and method described herein clearly address these and other needs.

SUMMARY OF THE INVENTION

Briefly, and in general terms, the claimed invention resolves the above and other problems by providing a configuration and management system for monitoring and controlling one or more gaming devices in a gaming system on at least one gaming floor. The system includes: one or more gaming devices in a gaming system; a processing and control system; and a server-side, graphical user interface including an interactive map of the gaming floor. Preferably, the one or more gaming devices in the gaming system, as well as the processing and control system, are interconnected via a network. The processing and control system acquires gaming performance data from the gaming devices in the gaming system. The server-side, graphical user interface includes an interactive map of the gaming floor. Additionally, the graphical user interface enables monitoring of the gaming performance data from the gaming devices in the gaming system. Further, the graphical user interface enables configuration of multiple gaming platform capabilities, multiple game titles, and multiple gaming parameters for each gaming device on the gaming floor. Preferably, the graphical user interface is interconnected to the processing and control system.

In another preferred embodiment, the network is a packet-based communication network. In one such embodi-
ment, the packet-based communication network comprises an IP-based message set that utilizes an interface layer between command-driven devices and logical communication channels. Continuing, in such an embodiment, the packet-based communication network implements the BOB (best of breed) protocol, SuperSAS protocol, or other similar packet-based protocol (e.g., G2S (Gaming 2 System)).

[0024] In another aspect of a preferred embodiment, the gaming devices include, by way of example only, and not by way of limitation: electronic gaming machines; embedded components, including game monitoring units, and player tracking user interfaces; gaming-related signage; and kiosks. Preferably, the gaming systems that are controllable by the configuration and management system include casino venues, class II venues, and lottery venues. In one aspect of a preferred embodiment, the gaming performance data includes, by way of example only, and not by way of limitation: coin-in activity, coin-out activity, meters, accounting information, security information, and player rating information. In still another aspect of a preferred embodiment, the gaming platform capabilities include platform-specific control over functions including, by way of example only, and not by way of limitation: volume settings, speed of play, hopper limits, log access, platform-specific reports, and asset information, including software and hardware bills of material. Preferably, the gaming platforms include, by way of example only, and not by way of limitation: Alpha, S6000, and Game Maker 2.

[0025] Other features and advantages of the claimed invention will become apparent from the following detailed description when taken in conjunction with the accompanying drawings, which illustrate by way of example, the features of the claimed invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0026] FIG. 1 illustrates a relational diagram of a gaming-content configuration and management system for controlling and managing a gaming system that includes gaming devices on a casino floor connected through networking equipment to multiple tiers of servers on the casino backend, wherein the operators manage the gaming floor from a computer via a graphical user interface;

[0027] FIG. 2 illustrates a map of the casino gaming floor via the graphical user interface of the gaming-content configuration and management system;

[0028] FIG. 3 illustrates another view of a map of the casino gaming floor via the graphical user interface of the gaming-content configuration and management system;

[0029] FIG. 4 illustrates a relational diagram of protocols implemented by a gaming-content configuration and management system for controlling and managing a gaming system that includes gaming devices on a casino floor connected through networking equipment to multiple tiers of servers on the casino backend;

[0030] FIG. 5 illustrates a front view of an IP gaming hub, constructed in accordance with the invention; and

[0031] FIG. 6 illustrates an system diagram of IP gaming hubs in an access layer connecting to a Distribution Layer and a Core Layer.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0032] Briefly stated, a preferred embodiment of the gaming-content configuration and management system is directed towards configuring and managing a scalable number of gaming devices using a centrally-connected user interface. The system configures and manages components that are multi-platform, multi-theme, multi-percentage, and multi-denomination. These gaming devices include, by way of example only, and not by way of limitation, electronic gaming machines (EGMs); embedded components, such as GMUs (Game Monitoring Units); and/or player tracking user interfaces (referred to sometimes herein as iView devices or Alpha devices). Such gaming devices further include any uniquely identifiable entity on the gaming floor, including by way of example only, and not by way of limitation, gaming-related signage and kiosks.

[0033] Referring now to the drawings, wherein like reference numerals denote like or corresponding parts throughout the drawings, and more particularly to FIGS. 1-4, there is shown a preferred embodiment of gaming-content configuration and management system 10. Specifically, FIGS. 1 and 2 show a gaming-content configuration and management system 10 that enables configuration, management, and delivery of content on a game floor 40 from a computer 50 via a graphical user interface 70.

[0034] In a preferred embodiment, the system 10 is responsible for the configuration, management, and download of code 20 (i.e., content) to gaming devices 30 (e.g., gaming machines, gaming machine component, system components, network components, kiosks, signage, gaming-related devices, and the like) on the gaming floors 40 of incorporated gaming venues. Preferably, such gaming venues include casinos, Class II venues, and lottery venues. In one preferred embodiment of the gaming-content configuration and management system 10, gaming machines 30 and system components are incorporated into a broadband-networked gaming floor 40, instead of operating independently (or quasi-independently) as stand-alone platforms and basic monitoring systems.

[0035] As briefly mentioned above, in one preferred embodiment, the gaming-content configuration and management system 10 enables operators to manage the gaming floor 40 from a desktop computer 50 (or other portable computer or hand-held device) via a graphical user interface 70 on the computer. Preferably, the gaming-content configuration and management system 10 is capable of administering gaming floors 40 ranging in size from a single slot floor to a worldwide gaming enterprise. In a preferred embodiment, the system 10 administers gaming devices 30 on floors 40 that are multi-platform 60, multi-theme, multi-percentage, and multi-denomination. Otherwise stated, in such an embodiment, each of the gaming devices 30 (or at least some gaming devices 30) incorporates multiple game platforms 60, incorporates multiple game titles (stored locally or remotely), is capable of being configured to generate multiple different payout percentages, and is capable of offering multiple different monetary denominations for game play. Central management of all these gaming options is enabled from the graphical user interface 70.

[0036] Accordingly, in a preferred embodiment of the gaming-content configuration and management system 10, a
A preferred embodiment of the gaming-content configuration and management system 10 presents customers with a consistent, intuitive, front-end interface 70 to all incorporated gaming devices 30. Preferably, tabs at the bottom of the graphical user interface 70 direct the operator from the configuration manager screen to other screens that control backside servers and/or services including, by way of example only, and not by way of limitation: MCC server 90, SDG server 92, CMP server 94, MindPlay server 96, SDS server 98, ACSC server 100, and the like. In a preferred embodiment, the graphical user interface 70 for the gaming-content configuration and management system 10 is an “entry point” (i.e., front-end interface) for all incorporated gaming devices 30. As such, the graphical user interface 70 of the gaming-content configuration and management system 10 provides a consistent “look and feel” for the operator as they use associated products. This same look and feel of the graphical user interface 70 is expandable over time to include various methods of user access to other categories of information, such as accounting, cage, and security across all back office servers (e.g., MCC server 90, SDG server 92, CMP server 94, MindPlay server 96, SDS server 98, ACSC server 100, and the like).

Within each gaming platform 60 (e.g., Alpha, S6000, Game Maker 2, EV03, and the like) the gaming-content configuration and management system 10 enables control of game theme (i.e., game title), game percentage payout, and game denomination. Thus, the configuration and management system 10 is able to control and manage a multi-platform 60, multi-theme, multi-percentage, and multi-denomination gaming floor 40. Additionally, a preferred embodiment of the gaming-content configuration and management system 10 also includes platform-specific control over functions such as the volume setting of the device, speed of play, hopper limits, and the like. Moreover, in a preferred embodiment, these functions further include, by way of example only, and not by way of limitation: access to logs, platform-specific reports, and asset information (e.g., software and hardware bills of material).

Thus, the configuration and management system 10 is capable of controlling game selection and gaming-related parameters, as well as controlling platform-specific functions. In a preferred embodiment of the configuration and management system 10, each gaming platform 60 has uniquely-controllable configurations, and the system 10 is capable of providing configuration and management control specific to each gaming platform 60. For example, the S6000 platform 60 sets and controls options in a different manner than the Alpha platform 60. In this regard, an Alpha platform 60 may have multiple methods for option setting (e.g., the platform may have a method for setting options for Class II gaming that is different from the method for setting options for Class III gaming). However, the configuration and management system 10 is capable of providing configuration and management control specific to each gaming platform 60.

In a preferred embodiment, the gaming-content configuration and management system 10 merges the capabilities of commercial system management products with the capabilities of commercial operating systems (e.g., Linux®, Windows®, or the like). Further, in one preferred embodiment, the gaming-content configuration and management system 10 is utilized in combination with the current SAS protocol, serial-based communication infrastructure. In such an embodiment, the gaming-content configuration and management system 10 employs several previously unimplemented poll codes contained in the SAS6 01 protocol. A preferred embodiment of the gaming-content configuration and management system 10, which utilizes this SAS protocol, serial-based communication network, (or similar non-SAS protocol, serial-based communication network) is referred to as Phase 1 of the configuration and management system 10.

In another preferred embodiment of the gaming-content configuration and management system 10, an IP-based (or other packet-based) communication network is implemented, which connects the gaming devices 30 in the system. An IP-based message set utilizes an interface layer between command-driven devices and logical communication channels. This embodiment of the gaming-content configuration and management system 10, which utilizes an IP-based (or other packet-based) network format, is referred to as Phase 2 of the configuration and management system 10. In one specific, non-limiting embodiment of a Phase 2 system 10, the SuperSAs protocol is implemented as the communication protocol. In another specific, non-limiting embodiment of a Phase 2 system 10, a different packet-based protocol (or other event-driven communication) is implemented as the communication protocol (TCP/IP, Frame Relay, and the like).

Referring again to Phase 1 of the gaming-content configuration and management system 10, in one preferred embodiment, the system modifies various platforms 60 (Alpha, S6000, GameMaker2) to enable selection of game theme (i.e., game title), game payout percentage, and game play denominations through the use of SAS6 01 commands. This configuration process enables platform-specific control over specific platform capabilities including, by way of example only, and not by way of limitation: volume setting of the device, speed of play, hopper limits, and the like.

In a preferred embodiment of Phase 1 of the gaming-content configuration and management system 10, the system identifies the configuration and control capabilities available in each gaming device 30, and targets those controllable capabilities remotely using the SAS6 protocol.
(or other non-SAS serial-based protocol). After identifying and targeting the available configuration and control capabilities, this protocol enables an administrator to configure and manage the existing systems, networks, gaming devices 30, and platforms 60 (e.g., NT+, Gearbox, MC250, GameNet, Alpha, Game Maker II, S5000, Mcc-Axiontek, and SDG game controller).

[0044] Preferably, in the Phase 1 version of the gaming-content configuration and management system 10, the SAS6 configuration control “long polls” are implemented on all platforms 60. Additionally, any integrated networks and systems are modified to send these poll codes. Further, the graphic user interface 70 in the system 10 is configured to control these poll codes.

[0045] Specifically, targeted SAS6 poll codes include, by way of example only, and not by way of limitation: (A) Shutdown (lock out play); (B) Startup (enable play); (C) Sound off (all sounds disabled); (D) Sound on (all sounds enabled); (E) Reel spin sound disabled; (F) Enable bill acceptor; (G) Disable bill acceptor; (H) Configure bill denomination; (I) Enable/disable game n; (J) Set sound volume; (K) Play sound; (L) Enable/disable real time reporting; (M) Send gaming machine ID# and information; (N) ROM signature verification; (O) Send EFT log; (P) Send current hopper status; (Q) Send total number of games implemented; (R) Send game n configuration; (S) Send SAS version ID, gaming serial no.; (T) Send selected game number; (U) Send enabled game numbers; (V) Send authentication info; (W) Send current date and time; (X) Receive general ASCII message; (Y) Simulate user input; (Z) Send enabled features; (AA) Send cash out limit; (BB) Enable/disable game auto rebet; (CC) Send extended game n info; (DD) Send enabled player denominations; and (EE) Send extended game n info. Additionally, there are SAS general poll exception commands, such as: (A) Operator changed options (configuration options); (B) System validation request; and (C) Game locked.

[0046] Referring now to Phase 2 of the gaming-content configuration and management system 10, the Phase 2 system transitions from using SAS6 protocols (or other serial-based network format) to instead utilizing broadband communications (e.g., Ethernet, TCP/IP, or other packet-based network format). The Phase 2 of the gaming-content configuration and management system 10 also enables: (1) Web-based communications (e.g., BOB, SuperSAS, G2S, and the like), and (2) access to logs and reports specific to the platform, and (3) downloading of new code and advertising content. Preferably, a SMS (Systems Management Server) client agent is also added to the platforms 60 in Phase 2 of the gaming-content configuration and management system 10.

[0047] In another aspect of a preferred embodiment, Phase 2 of the gaming-content configuration and management system 10 also includes the control and auditing of system configurations. For example, the reporting and settings options in a SDS server 98 are typically different than settings options in an MCC server 90, SDG server 92, or ACSC server 100. However, a preferred embodiment of the gaming-content configuration and management system 10 is able to control and audit each of these system configurations. In another aspect of a preferred embodiment, an iView device 30 is controlled by the gaming-content configuration and management system 10, which has setup and control options that are unique in each of the NT, Kontron board, and Mcc implementation.

[0048] In a preferred embodiment of the gaming-content configuration and management system 10, platforms 60 include Ethernet hardware, TCP/IP stacks, http stacks, SOAP (or the proprietary layer SuperSAS), and XML handling capability. Preferably, system management client agents for each platform and each system are employed. In one preferred embodiment, these elements are added to each platform and are “hooked” into the platform code in order to tie XML messages to game logic. In another aspect of one preferred embodiment that utilizes on Alpha platform 60, a SMS client for Linux is implemented in order to support the Alpha platform.

[0049] Referring again more specifically to FIGS. 2 and 3, in a preferred embodiment of the gaming-content configuration and management system 10, the graphical user interface 70 displays the slot floor (or multiple slot floors) to the gaming floor administrators on their computers 50. Specifically, the graphical user interface 70 preferably presents a map 74 of the gaming floor and incorporates the use of selectable layers 80 (for organizing information) and colors (for emphasizing information). The layers 80 are selectable in order to present various types of information by layer, including by way of example only, and not by way of limitation: occupancy, level of handle, sound level, heat, accounting, and performance measurements.

[0050] In one preferred embodiment, the graphical user interface 70 is extended to incorporate all user input screens. In this manner, users have a consistent “front-end” experience when working with any of the included user input screens, such as for the cage, accounting, security, and the like.

[0051] In one preferred embodiment of the Phase 1 system 10, information obtained from gaming devices 30 on the floor by the SAS6 protocol (or other suitable protocol) is translated by the graphical user interface 70 into a multi-dimensional graphic form that includes geographic location (e.g., country, state facility, slot floor position, and the like) and value (e.g., hi, lo, medium, empty, full, and the like) which are preferably represented by different colors. As mentioned above, in a preferred embodiment, the graphical user interface 70 includes information on available game themes, game payout percentages, and available game play denominations. Further, the graphical user interface 70 not only displays this information, but also enables an operator to configure the gaming devices 30 on the gaming floor remotely from a computer 50 via the graphical user interface. In this manner, the graphical user interface 70 enables an operator to select a single gaming device 30, or a group of gaming devices 30, and change their configuration (theme, percentage, denomination, and the like). Additionally, the graphical user interface 70 preferably enables the scheduling of changes. Other configuration setting provided by SAS6 (or other suitable protocol) and the platforms 60 are also presentable and configurable, via the graphical user interface 70.

[0052] In a preferred embodiment, the graphical user interface 70 of the Phase 1 system 10 is an analysis program that provides front-end, user interface functionality including, by way of example only, and not by way of limitation:
In a preferred embodiment of the Phase 2 system 10, all content 20 (e.g., platform OS code, game theme code, platform options-configuration, logs by cabinet, advertising content-skins, and the like) is securely stored at a level sufficient to satisfy gaming regulators. These security measures include, by way of example only, and not by way of limitation, physical security requirements, access requirements, logging requirements, and update requirements. In a preferred embodiment of the Phase 2 system 10, the procedure for authenticating code 20 with gaming regulations is to require a server to meet the same compliance requirement as a gaming device 30. In this manner, the server (and contained code) is subject to corresponding gaming device regulations. For content 20 such as options-configuration and advertising content (e.g., skins), an authentication procedure is implemented that links the production of new content into storage and subsequent authentication signing.

In another aspect of a preferred embodiment, the gaming-content configuration and management system 10 further includes a distribution management component. Briefly stated, the distribution management component transmits bulk data from a backend server to the gaming floor. Movement of large files to particular platforms 60 on the floor must be performed without disrupting the primary use of the gaming floor (i.e., making money through the support of gaming-related transactions). Thus, large files of bulk data are moved "in the background" over otherwise unused network bandwidth so as not to adversely affect gaming-related transactions.

Accordingly, in a preferred embodiment of the gaming-content configuration and management system 10, platforms 60 (i.e., clients) and systems (i.e., servers) are capable of downloading large files of bulk data while gameplay is in progress. Preferably, this download process is schedule-able and monitor-able using the distribution management component. Typically, downloading of large files (or upload of large files such as logs) takes a large amount of time (on the order of hours, days, or long periods of time). In a preferred embodiment, the download is performed at the request of the client (i.e., the platform 60). As such, the client and network load combine to determine the proper time and speed for a download (or upload) to take place. In a preferred embodiment of the gaming-content configuration and management system 10, the server accommodates download scheduling, ensures minimal bandwidth impact, enables progress reporting, and guarantees delivery, as well as setup and management of the download (or upload) process.

In a preferred embodiment of the Phase 1 system 10, floor control is limited to the configuration changes that are possible through SAS (or other equivalent protocol). As such there is no additional distribution management functionality in the Phase 1 system 10. However, the broadband networking utilized in a preferred embodiment of the Phase 2 system 10 does implement distribution management features. In one preferred embodiment, when the content 20 is stored on alterable media (e.g., a local hard drive, FLASH memory, and the like) in the platform 60 (Alpha, VView, Game Maker II, G2S, and the like), command protocols such as GSA BOB v1.01 can be used for enabling and disabling gaming combination. In one preferred embodiment of the Phase 2 system 10, operators are able to modify these configuration elements (i.e., gaming combinations) in real
time. In one specific, non-limiting embodiment, the server communicates in the GSA BOB v1.01 command protocol to the slot floor.

[0059] Continuing, in a preferred embodiment of the gaming-content configuration and management system 10, distribution management includes, by way of example only, and not by way of limitation: (1) the act of downloading new advertising content 20 to an iView device 30 or gaming platform 60 (2) sending down code 20 or operating system updates, and (3) sending down a new game theme (i.e., game title). New game themes are typically large files that can range from around 400 Kilo-bytes to over 4 Giga-bytes in size. Code updates are typically smaller files that range from around 20 Kilo-bytes to 400 Mega-bytes in size.

[0060] In one specific, non-limiting embodiment, a slot director uses the gaming-content configuration and management system 10 to schedule a download (or upload) and check on the progress of the download. For example, in one scenario, the system 10 rolls out a large new game theme across a casino floor to several hundred cabinets 30 over several days. Downloading such a game theme in the background to a gaming machine fulfills Class III regulations, provided that (1) the content 20 is downloaded into an “escrow” area where the content cannot affect gameplay, and (2) an authentication process is performed on the newly-downloaded content. In some situations, installation and use of the downloaded content 20 may require physical intervention, an initiating event, and/or approval to fulfill Class III regulations (e.g., using a key switch, BKEY, or the like), depending upon the jurisdiction.

[0061] In one preferred embodiment, an initiating event includes, by way of example only, and not by way of limitation: (1) no credits on the game meters, (2) no activity at the game, game play, button pushes, card-ins, printing, and the like, (3) a period of time with no activity at the game, (e.g., 5 minutes, 10 minutes, or the like), (4) a key insertion or card insertion by an employee, (5) accessing of a special setup screen on the game by an authorized person, (6) touching a button or activation point on the screen in response to a message saying the new code is ready to load, (7) a button push or activation by an operator on the casino backend, (8) a tie-in to a video system to confirm there is no player at the game and the initiation can take place, (9) a biometric entry at the game or at the system that authorization of the code, and (10) a key opening and BKEY (electronic key) entry to authorize installation or reconfiguration of the software.

[0062] In one preferred embodiment of the gaming-content configuration and management system 10, the distribution management is performed using Microsoft SMS on the server, iView device 30, and Game Maker II. In another preferred embodiment, WBEM (Web Based Enterprise Management) is implemented, which provides an open-source option for LINUX, AIX, UNIX, AS400, and homogenous clients. The distribution management abilities of the configuration and management system 10 enable other game manufacturers or system manufacturers to be monitored and controlled by the management server of the system 10, which is typically required for lottery and casino monitoring systems. Additionally, the distribution management client software utilized in the system 10 is adaptable and/or accessible to other manufacturers.

[0063] As mentioned above, in a preferred embodiment of the system 10, a key feature of distribution management is to ensure availability of the network for gaming transactions (i.e., device management may not dominate the bandwidth of the network). Another important aspect of a preferred embodiment is flexibility in the deployment of distribution management system and scalability of the system. Otherwise stated, the ability to use the same distribution management system in multiple situations. Such situations include, by way of example only, and not by way of limitation: (1) a point-to-point distribution management situation in which a laptop (or other portable computing device) connects to a single device 30 or a small number of devices; (2) a property-based distribution management situation in which hundreds to thousands of devices 30 are connected over a combination broadband network and/or dial-up facilities.

[0064] In one preferred embodiment of the gaming-content configuration and management system 10, the data transport is a switched, managed IP network of at least 100 Mbps. Preferably, each endpoint in the network is monitorable and controllable. With respect to another preferred embodiment, the distribution management system operates over a data transport based upon POTS (plain old telephone system).

[0065] Referring now to another aspect of the gaming-content configuration and management system 10, the device management component is the client companion component to the distribution management component discussed above. One preferred embodiment, the system 10 utilizes a common server-based distribution engine that communicates with a wide range of “clients” including, by way of example only, and not by way of limitation: the LINUX-based Alpha platform; the C6-based iView platform; the XPe based Game Maker II platform; and other proprietary platform operating systems (e.g., QNX, home grown, and the like). The device management component of gaming-content configuration and management system 10 also includes systems products, including by way of example only, and not by way of limitation: Windows server, AIX, UNIX and AS400.

[0066] In one preferred embodiment, since the Phase 1 system 10 enables floor control through configuration changes in SAS protocol (or other equivalent protocol), all current platforms 60 are configured to respond to these SAS poll codes. As such, in the Phase 1 system 10 poll codes are implemented and/or modified in their response as needed.

[0067] Referring now to the Phase 2 system 10, in one preferred embodiment Microsoft SMS provides all of the necessary client components. In another preferred embodiment, WBEM (Web Based Enterprise Management) is implemented, which provides an open-source option for LINUX, AIX, UNIX, and AS400 clients.

[0068] In preferred embodiments of the gaming-content configuration and management system 10, the network infrastructure differs depending on whether Phase 1 or Phase 2 of the system is being implemented. In a preferred embodiment of the Phase 1 system 10, the system is implemented over existing networks using SAS poll codes (or
another equivalent protocol). In a preferred embodiment of the Phase 2 system 10, the system is implemented over a broadband network and employs new message protocols (e.g., BOB, SuperSAS, G2S, or the like). In one preferred embodiment, the network is constructed using copper or fiber optics. Additionally, the network may include wireless, VPN, and/or long-haul components. In a preferred embodiment, the system 10 uses a fully-switched network in which each port (down to the individual terminal 30, game, platform 60, and/or iView device 30) is monitored and controlled.

[0069] Due to increasing threats from hacking and other security issues, gaming regulations in Class 3 jurisdictions dictate the use of strong cryptographic authentication of code running on gaming platforms. As such, a preferred embodiment of the gaming-content configuration and management system 10 has adopted cryptography and security standards in order to help ensure operational efficiency and inter-operability with other products. In this regard, PKI (public key infrastructure) is the root of a common, systematic approach to security and authentication for the configuration and management system 10. In a preferred embodiment, code 20 is signed and authenticated on platforms 60 using a root authority with subsidiaries that meet the highest cryptographic standards and employ industry standards.

[0070] Referring now to FIGS. 1 and 4, the iView device 30 of a preferred embodiment of the gaming-content configuration and management system 10 is shown. Prior to the advent of the iView device (described above), gaming regulators would have been unwilling to allow casino operators to design their own content. However, due to the cryptographic technology implemented by the embedded processor in the iView device 30, a certification process is provided by the system 10 with sufficient security for gaming regulators to allow casino operators to design their own content. Specifically, in one preferred embodiment, the certification process offered ensures authenticity and non-repudiation of the casino operator designed web content. Preferably, in the configuration and management system 10, the certification process provided further ensures auditability and traceability. Various cryptographic technologies, such as authentication and non-repudiation (described herein below), are utilized in preferred embodiments of the claimed invention, to provide sufficient security for gaming regulators to allow casino operators to design their own content.

[0071] In one preferred embodiment, this certification process is used to certify “signed content” (created by the casino owners) in the same manner that a “signed program” is certified. Preferably, PKI (Public Key Infrastructure) is utilized in the certification process. PKI is a system of digital certificates, Certificate Authorities, and other registration authorities that verify authenticity and validity. In one preferred embodiment, a “new tier” or derivative PKI is created that is rooted in the primary PKI and that leverages the capabilities of the certificate (e.g., a x509 certificate) that allow for limited access. Thus, this preferred embodiment allows the attributes within the certificate to be used to provide “levels” of code access and acceptance in the gaming industry.

[0072] In one embodiment, the content is protected by digital signature verification using DSA (Digital Signature Algorithm) or RSA (Rivest-Shamir-Adleman) technology. In this regard, the content is preferably protected using digital signature verification so that any unauthorized changes are easily identifiable. A digital signature is the digital equivalent of a handwritten signature in that it binds a trusted authority’s identity to a piece of information. A digital signature scheme typically consists of a signature creation algorithm and an associated verification algorithm. The digital signature creation algorithm is used to produce a digital signature. The digital signature verification algorithm is used to verify that a digital signature is authentic (i.e., that it was indeed created by the specified entity). In another embodiment, the content is protected using other suitable technology.

[0073] In one preferred embodiment, a Secure Hash Function-1 (SHA-1), or better, is used to compute a 160-bit hash value from the data content or firmware contents. This 160-bit hash value, which is also called an abbreviated bit string, is then processed to create a signature of the game data using a one-way, private signature key technique, called Digital Signature Algorithm (DSA). The DSA uses a private key of a private key/public key pair, and randomly or pseudo-randomly generated integers, to produce a 320-bit signature of the 160-bit hash value of the data content or firmware contents. This signature is stored in the database in addition to the identification number.

[0074] In another preferred embodiment, the claimed invention utilizes a Message Authentication Code (MAC). A Message Authentication Code is a specific type of message digest in which a secret key is included, as part of the fingerprint. Whereas a normal digest consists of a hash (data), the MAC consists of a hash (key+data). Thus, a MAC is a bit string that is a function of both data (either plaintext or ciphertext) and a secret key. A Message Authentication Code is attached to data in order to allow data authentication. Further, a MAC may be used to simultaneously verify both the data integrity and the authenticity of a message. Typically, a Message Authentication Code (MAC) is a one-way hash function that takes as input both a symmetric key and some data. A symmetric-key algorithm is an algorithm for cryptography that uses the same cryptographic key to encrypt and decrypt the message.

[0075] A Message Authentication Code can be generated faster than using digital signature verification technology; however, a Message Authentication Code is not as robust as digital signature verification technology. Thus, when speed of processing is critical, the use of a Message Authentication Code provides an advantage, because it can be created and stored more rapidly than digital signature verification technology.

[0076] In one preferred embodiment, the authentication technique utilized is a BKEY (electronic key) device. A BKEY is an electronic identifier that is tied to a particular trusted authority. In this manner, any adding, accessing, or modification of content that is made using a BKEY for authentication is linked to the specific trusted authority to which that BKEY is associated. Accordingly, an audit trail is thereby established for regulators and/or other entities that require this kind of data or system authentication.

[0077] Another preferred embodiment of the verification system utilizes “component bindings” for verification using cryptographic security. In component binding, some com-
ponents come equipped with unalterable serial numbers. Additionally, components such as web content or the game cabinet may also be given another random identification number by the owner. Other components in the system, such as the CMOS memory in the motherboard, the hard drive, and the non-volatile RAM, are also issued random identification numbers. When all or some of these numbers are secured together collectively in a grouping, this protected grouping is referred to as a “binding.” Each component of the machine contains its portion of the binding.

[0078] In one such preferred embodiment, every critical log entry made to the content is signed with a Hashed Message Authorization Code (HMAC) that is based on the entry itself, and on the individual binding codes. In this manner, the security produced by the bindings ensures that log entries that are made cannot be falsified or repudiated.

[0079] After the critical gaming and/or system components are selected, given individual identifiers, and combined into a protected grouping that is secured using the component “bindings,” any changes to those components will then be detected, authorized, and logged. For example, content within the binding is digitally signed (SHA-1) using the key derived from the bindings. This signature is verified whenever an entry is made to a component within the binding. If the signature is wrong, this security violation and the violator are noted, but typically the entry is not prohibited. In other embodiments, the entry may be prohibited as well. Thus, the component produces a cryptographic audit trail of the trusted authority making changes to any of the components within the binding.

[0080] Moreover, bindings ensure that the critical components of a gaming machine system, or the content utilized therein, that have been selected to be components within the binding have not been swapped or altered in an unauthorized manner. Preferably, bindings use unique identification numbers that are assigned to vital parts of the gaming platform including, by way of example only, and not by way of limitation: the cabinet, motherboard, specific software, non-volatile RAM card, content (data), and hard drive. These identification numbers combined in a cryptographic manner to form a “binding” that protects and virtually encloses the included components, such that no component within the binding can be modified, removed, or replaced without creating an audit trail and requiring authentication. Thus, for one of these components within the binding to be changed, appropriate authentication is required and a log file entry is made documenting the activity and the identity of the trusted authority making the change. In one preferred embodiment, a specific level of BKEY clearance or classification is required to make specific changes.

[0081] As briefly described above, gaming devices 30 also includes signage and kiosks, in addition to gaming machines, GMUs, and iView devices. In this regard, gaming-related signage relates to advertising signage that is typically in a reconfigurable electronic format. In this context, gaming-related kiosks are machines that provide gaming-related service but do not provide actual game play itself. Gaming-related kiosks may include both patron-oriented services and maintenance-oriented features. In one embodiment, patron-oriented services include the ability to sign on to rewards services, view account status and history, redeem payout tickets and promotional “comps,” request help from an attendant, order drinks, make dinner reservations, reserve taxis, purchase show tickets, conduct banking transactions, and the like. Maintenance-oriented features include providing information such as coin-in, coin-out, malfunctions, jackpots, tilt conditions, game software version, and the like.

[0082] As described below, an iView device is an embedded additional user interface, which is preferably integrated into a gaming machine and acts to increase user excitement by providing a richer gaming experience. An embedded additional user interface provides enhanced player satisfaction and excitement, as well as improved gaming device reliability, interactivity, flexibility, security, and accountability. The user interface is sometimes referred to herein as “additional” in that the user interface is separate from the gaming screen (or other gaming presentation). Further, the user interface is sometimes referred to herein as “embedded” in that the user interface includes its own processor in some preferred embodiments.

[0083] In one preferred embodiment, the gaming-content configuration and management system 10 contains a datastore that includes, by way of example only, and not by way of limitation: a relational database, object database, a flat file, an ASCII list, registry entries, an XML file, a “collection” (i.e., in a SQL (structured query language) environment, a collection of parameter defined data in an object database), or any other type of commonly known data listing. In such a preferred embodiment, the computer datastore enables the system 10 to sort gaming devices 30 by feature, whether the gaming devices are electronic gaming machines (EGMs), GMUs, iViews (embedded additional user interfaces), or any other uniquely identifiable entity on the gaming floor. In one aspect of a preferred embodiment, the gaming devices 30 being tracked and/or sorted include a download feature that is sortable according to: (a) the make/model of the gaming device that the download feature is associated therewith, (b) the device’s hardware revision, (c) the device’s firmware revision, (d) the physical location of the gaming device on the property, (e) zoning of the gaming device (e.g., high roller zone), (f) game type (e.g., mechanical, electrical, dual screen, and the like), (g) dynamic gaming state or state change (e.g., payout, malfunction, “game in use,” offline, tilt, jackpot mode, turned off, authentication failure, security breach, downloading content, installing content, and the like), (h) IP (Internet Protocol) address or (i) other suitable sorting feature, such as MAC addresses.

[0084] In one exemplary embodiment, all gaming devices 30 in a particular group can then be targeted for a specific code download. Accordingly, in one specific embodiment, all GMUs with a particular code revision can be identified and upgraded while those GMUs outside of the group are ignored. In another example, all iView devices installed into gaming machines that are located in a particular physical location on the property (i.e., a particular bank of games) are identified, and receive downloaded content which is then authenticated, after which they are reconfigured. Meanwhile, all of the iView devices outside of that group are ignored.

[0085] As mentioned above, the computer datastore of the gaming-content configuration and management system 10 is capable of utilizing these sorting and grouping capabilities
for the purpose of inventory management. In this regard, a property (e.g. casino) is able to maintain up-to-date information on gaming floor inventory for a multitude of inventory parameters. These inventory parameters include, by way of example only, and not by way of limitation, the name of the iView device, the hardware revision of the iView device, the firmware revision of the iView device, the content of the iView device, the make/model of the GMU, the hardware revision of the GMU, the firmware revision of the GMU, the make/model of the gaming machine, the hardware revision of the gaming machine, the firmware revision of the gaming machine, and the physical location of the gaming machine.

[0086] In one preferred embodiment, the gaming-content configuration and management system 10 either queries the datastore containing all of the gaming device inventory data. The gaming-content configuration and management system 10 then sorts the data according to one or more user-input parameters. After the sorting has occurred, the user can, for example, download new content 20 to the iView devices, once the devices have been identified and targeted.

[0087] In a preferred embodiment of the gaming-content configuration and management system 10, since the device data resides on a central computer datastore, standard binary datastore searches can be performed to produce specifically desired reports. However, in one preferred embodiment, a distributed datastore is used instead of a centralized datastore. In one particular example, an analyst may be interested in the effectiveness of one piece of content (content X) compared to another piece of content (content Y) in a particular brand of gaming machine. Using the configuration and management system 10, the analyst can perform a datastore query on various parameters of the gaming devices, for example, the “coin-in” count on all Blazing 7’s style gaming machines with iView gaming devices running content version X and content version Y. In this manner, the configuration and management system 10 enables specialty reporting, efficiency analysis, and gaming device management with a level of organization and simplicity that was never before possible.

[0088] In another preferred embodiment, the standard binary datastore searches are performed to produce other specifically desired reports, such as predictive analysis and yield management. In one embodiment, the yield management data includes projection data calculated based on one or more factors related to use of one or more gaming machines. For example, in one preferred embodiment, the yield management data includes game play projection data, machine usage projection data, and/or income projection data calculated based historical game play data for the one or more gaming machines. In one preferred embodiment, the calculations are performed using linear regression analysis. In another preferred embodiment, the calculations are performed using a neural network. In one embodiment, yield management data is used to determine one or more bonuses.

[0089] A preferred embodiment of the gaming-content configuration and management system 10 incorporates a yield management feature for the purpose of optimizing floor drop using configuration control over slot machines. The yield management feature of the configuration and management system 10 implements configuration control by setting optionable parameters including, by way of example only, and not by way of limitation: wager, theme, percentage and time in play. The analysis and predictive results are displayed using the graphical user interface 70 that presents a map 74 of the gaming floor, preferably, with click and grab ease of planning and scheduling new gaming configurations.

[0090] A preferred embodiment of the gaming-content configuration and management system 10 provides automation and future-looking guidance to slot directors in configuring parameters for slot machines in order to optimize floor drop over some period of time: hour, day, week, month, year using inputs, including by way of example only, and not by way of limitation: accounting, time of day, civic, news and entertainment events, and player status.

[0091] As mentioned above, a preferred embodiment of the gaming-content configuration and management system 10 includes a graphical user interface 70 to simplify the use of these complex tools. The graphical user interface 70 presents a map 74 of the gaming floor that makes the yield management results clear and comprehensible to those not highly skilled in the art of yield management. Further, the graphical user interface 70 of the gaming-content configuration and management system 10 accepts input to the yield management feature, thereby allowing a casino operator the personalized control to manage the yield management process in the most logical/understandable/comprehensive manner. The input parameters and requirement for the graphical user interface 70 are also configured to be allowable subject to the gaming regulations for the relevant jurisdiction.

[0092] A preferred embodiment of the gaming-content configuration and management system 10 is able to analyze, automate, schedule, and control the options, operation, and configuration for thousands of machines. The configuration and management system 10 is capable of providing this control from a single property to many properties that may span states, countries, and even throughout the world. Preferably, a map 74 is presented via the graphical use interface 70 of the system 10, which is used to present information to a casino administrator in an easily understandable format. In this manner, a casino administrator is able to see historical results and then schedule changes in the slot floor using the map 74, presented via the graphical use interface 70.

[0093] In one preferred embodiment, the configuration and management system 10 is capable of applying the yield management feature to an individual player. In another aspect of a preferred embodiment, the configuration and management system 10 utilizes two forms of yield management in combination (e.g., physical groupings combined with individual player performance and monitoring).

[0094] In one preferred embodiment, yield management feature of the configuration and management system 10 is configured to optimize casino profitability. In one specific, non-limiting preferred embodiment, casino profitability is represented by the formula:

\[ CP = \sum_{i=1}^{n} (OP - OE) \]
Additionally, in one preferred embodiment of the configuration and management system \(10\), time is a variable in yield management calculations. Further, it should be noted that operational expenses are included in the above casino profitability formula. In a preferred embodiment, many aspects of operations performance are captured in the systems and messages. An additional aspect of the configuration and management system \(10\) involves applying yield management principles to operational efficiency issues, thereby further increasing casino profitability.

In a preferred embodiment, each element of the operations profit formula (shown below) can be broken down and the principles of yield management applied. For the casino slot floor the operations profit, \(OP\), can be broken into:

\[
OP = \sum \left( \text{POSP} + \text{SFD} \right)
\]

Where:

- \(\text{POSP}\) = Point Of Sale Profit (includes hotel, retail, food and beverage and entertainment)
- \(\text{SFD}\) = Slot Floor Drop

Continuing:

\[
SFD = \sum (PL - \text{promotions}(\text{RETURNVISIT}))
\]

Where:

- \(\text{RETURNVISIT}\) = probability that the player will return to the casino.
- \(\text{PL}\) = Player Loss
- Promotions = marketing money the casino contributes to player kickbacks, comps, and system games.

Still continuing:

\[
\text{PL} = \text{ST} \times \text{GCT} \times \text{HPC} \times \text{WAGER}
\]

Where:

- \(\text{ST}\) = time the player spends at the slot machine, i.e., seat time
- \(\text{GCT}\) = Game Cycle Time
- \(\text{HPC}\) = Hold Percentage for the game

Further continuing:

\[
\text{WAGER} = \text{LINESBET} \times \text{CREDITS} \times \text{DENOM}
\]

Where:

- \(\text{LINESBET}\) is the number of lines on which the player is betting.
- \(\text{CREDITS}\) is the number of credits the player chooses to bet.
- \(\text{DENOM}\) is denomination, i.e., the worth of an individual credit.

It should be noted that \(\text{LINESBET}, \text{CREDITS}, \text{and DENOM}\) can each be set to a minimum and are adjustable parameters. As such, \(\text{LINESBET}, \text{CREDITS}, \text{and DENOM}\) are each under yield management control. Interestingly, changes in parameters within the \(\text{PL}\) (Player Loss) formula above can have a significant effect. Even if \(\text{PL}\) (Player Loss) is held constant, other elements can still be modified within the formula. For example, \(\text{GCT}\) (Game Cycle Time) could be reduced by half while \(\text{ST}\) (Seat Time) is doubled. In this scenario, the player spends much more time at the game. Accordingly, such a player’s chances of winning a progressive or system game are increased. Continuing this example, during slow times for the casino the above-described configuration change provides a method for the casino operator to enhance the attractiveness of the games to players without adversely compromising player loss or modifying progressive rules or systems games. The capability of the configuration and management system \(10\) provides a distinct advantage over prior gaming systems, in that no regulatory review of “new game rules” (i.e., new game configuration) is required.

A preferred embodiment of the configuration and management system \(10\) includes the capability to link the above-described changes to marketing programs such as mailings, advertisements, phone calls, other marketing methods, and the like. In addition, configuration and management system \(10\) includes a linkage to system game operation and individual yield management, as described above.

In one preferred embodiment of the configuration and management system \(10\), the yield management feature of the system \(10\) includes the ability to advertise, annunciate, and/or otherwise alert the player that yield management configuration change has occurred. Otherwise stated, in one specific, non-limiting embodiment, when the player sits at a gaming machine and is identified, the configuration and management system \(10\) annunciates to the player, “you are at 98% payback.” In one preferred embodiment, such an announcement is made and maintained for the player to observe through at least one game cycle.

In another aspect of a preferred embodiment of the configuration and management system \(10\), the yield management parameter modifications are applied interactively as the casino operates. For example, in one specific, non-limiting embodiment, every fifteen minutes, the “forward looking” algorithms for yield management operation note that a particular carousel is being heavily played. In such an embodiment, yield management parameters (e.g., minimum bet and the like) are then immediately modified on those gaming cabinets (in the carousel) that are not currently in play. Thus, any new players joining the “hot” carousel are joining into game play that has had “tighter” yield management parameters applied. Accordingly, in such an example, those gaming patrons already on the “hot” carousel who
have been a part of creating the "hot" feeling are at an advantage to those players joining later.

Likewise, in another specific, non-limiting embodiment, if the “forward-looking” algorithms for yield management operation detect that a carousel is “cooling,” then yield management parameters (e.g., denomination and the like) can be immediately lowered or modified for ALL players. In this manner, those loyal players receive the same reward as new players joining the “action.” Moreover, from a regulatory standpoint, relaxing yield management parameters on players during a gaming session is viewed far less restrictively than tightening yield management parameters on players during a gaming session. In this regard, in one preferred embodiment, tightening yield management parameters on players requires at least an announcement (and possibly active acceptance of the modifications by the player), and more commonly instituting the above configuration changes between player sessions.

In a preferred embodiment of the configuration and management system 10, the yield management feature necessitates an audio and/or visual announcement to the players that yield management parameters have been changed. In this regard, parameter changes in the players’ favor may be displayed on the game screen, presented in the systems interface (iView-type device), announced by sound and/or the like. As explained above, parameter changes that are not in the players’ favor (i.e., changes that tighten yield management parameters on the players) typically require higher levels of announcement to the players and possibly active acceptance of the modifications by the players.

Referring again to the formula above, slot floor drop, the parameter RETURNVISIT (probability that the player will return to the casino) is a significant term. In a preferred embodiment of the configuration and management system 10, yield management accounts for the importance of maximizing the RETURNVISIT probability, while at the same time maximizing SFD (Slot Floor Drop, i.e., the money collected). In a preferred embodiment of the system 10, a balance between these two elements is significant, and advantageously, is customizable by a casino administrator through the use of the yield management feature of the configuration and management system 10.

In a preferred embodiment of the system 10, the yield management feature enables cyclic patterns to be identified in order to both increase operator profitability and optimize player satisfaction, and thus return visits. Such factors, which are examined by the yield management feature in determining such cycles include, by way of example only, and not by way of limitation: demographics, weather, and entertainment events. In a preferred embodiment of the system 10, use of the yield management feature enables casinos that have implemented the system 10 to provide a much more personalized and individualized gaming experience.

In another aspect of a preferred embodiment of the system 10, the yield management feature combines individual player performance over time with gross property-wide yield management information. This combination gives each player their own unique play characteristics. In this regard, individualized characterization, control, and promotion are prominent features of such an embodiment. By combining yield management with player information, the system 10 enables customization of the game offerings specific to that customer.

Thus, in one specific, non-limiting embodiment, if a game cabinet holds fifteen game themes (i.e., game titles), only those game themes that the yield management predicts are most attractive to the player will be presented. Preferably, this extends to new game offerings as well, so that when new game themes are introduced, the yield management feature predicts if a particular player might like this new game theme, provides that game theme to the player, and announces to the player the existence of the new game theme. Additionally, as described above, parameters such as wager, game cycle time, and percentage can be set by the system 10, based upon player characteristics and overall yield management parameters.

In another specific, non-limiting embodiment of the configuration and management system 10, if the “forward-looking” yield management algorithms predict over 80% occupancy then GCT (game cycle time) is reduced, thereby increasing profitability. Moreover, if indications are that occupancy will remain over 80%, then yield management can move to adjusting WAGER to higher minimums. In one preferred embodiment, this adjustment might take the form of changing minimum lines, minimum credits, or denomination. As described above, the yield management feature of the configuration and management system 10 has a wide area of variables for affecting and adjusting slot floor profit.

In a preferred embodiment, the yield management aspect of the configuration and management system 10, coordinates game performance data from multiple input sources into an analytic engine. The sources include, by way of example only, and not by way of limitation: (1) slot data accounting, (2) multi-game cabinet accounting, (3) player tracking data, comps, (4) hotel, (5) point of sale system data, (6) location, (7) game mix near by, (8) entertainment data, (9) weather, (10) off site user group demogrophic data, and (11) grouping of players, including the monitoring of those groups and presentation of bonusing specific to that group.

In accordance with a preferred embodiment of the system 10, the regulatory rules that allow control over gaming devices by electronic means are (1) GLI-21, and (2) NVGCDB Proposed System Based and System Supported gaming regulations. Gaming devices with one or more modifiable parameters affecting yield management calculations include, by way of example only, and not by way of limitation: (1) theme, (2) wager (a) minimum bet, (b) maximum bet, (c) minimum lines bet, and (d) denomination, (3) percentage, and (4) play time, (a) spin cycle time, and (b) bonus round time.

In a preferred embodiment of the system 10, the uses of the yield analysis feature, include by way of example only, and not by way of limitation: system-games, gaming user groups, casino gaming areas, casinos and multi-property gaming, base game play of relating system-games, and modification of system-game operation for optimization of overall property profitability. In another aspect of a preferred embodiment of the system 10, the yield analysis feature includes predictive analysis engine for optimizing any desirable parameter (e.g., drop or occupancy during some future time). In one preferred embodiment of the system 10, the
yield analysis feature includes an automation system for aiding and advising slot floor managers in the optimal configuration of a casino floor, including individual parameterization of slot machines.

A preferred embodiment of the yield management aspect of the system 10 is directed towards manipulation of gaming device parameters including, by way of example only, and not by way of limitation: wager, theme, percentage, and time in play to provide optimal casino profitability based upon predictive modeling. Additionally, in another aspect of a preferred embodiment, predictive modeling includes parameters related to player, property occupancy, time of day, week, month, year, events, weather, demographic, and other similar parameters.

Another preferred embodiment of the yield management aspect of the system 10 is directed towards linkage of yield management manipulation of gaming devices 30 with player-targeted marketing, including advertisements and inducements from casino to patrons. Still another preferred embodiment the yield management aspect of the system 10 is directed towards notifying a player for at least one game cycle that a yield management parameter has been modified on the gaming device being used by the player. Moreover, yet another preferred embodiment the yield management aspect of the system 10 is directed towards a system 10 configured to combine message set capability with game design, wherein the game design enables capturing, analyzing, and reporting on individual machine, machine grouping, as well as individual player and player grouping performance over time.

Referring now to FIG. 5, a preferred embodiment of an IP gaming hub 200 is utilized as a controlled access device that includes a game monitoring system 210, an internal Ethernet switch 220, and a plurality of ports 230. A game monitoring system 210 has the functionality of a GMU, as described above. Typically, a GMU is an in-cabinet device that connects the internal components of a gaming device to the network. In one preferred embodiment, the IP gaming hub 200 can be embodied as an advanced Mastercom type of device (but incorporating many additional types of functionality beyond that of prior Mastercom devices), as sold by Bally Gaming of Las Vegas Nev.

Preferably, the internal Ethernet switch 220 is not controlled by port location. In one preferred embodiment, the IP gaming hub 200 includes a 6-port Ethernet switch 220. Preferably, one of the ports 230 is the uplink port (in QoS vernacular, the “eregress port”). Continuing, in such a preferred embodiment, four of the ports 230 are used to connect to any Ethernet device within the game cabinet. These ports 230 are connectable to the game motherboard, iView-type devices, Alpha-type devices, and the like. Typically, the last of the ports 230 is used internally for SNMP (Simple Network Management Protocol) and formation of the GMU/SDS data packets. Simple Network Management Protocol is a method for a network device to communicate management and error information to a remote server. SNMP can also be used to query a device for information about the device. The SNMP protocol can support monitoring of network-attached devices for any conditions that warrant administrative attention. One of ordinary skill in the art will appreciate that other standard broadcast protocols, networks, switches, and ports, may be substituted for Ethernet in other embodiments of the invention.

As shown in FIG. 6, the network includes a core layer 301 over a distribution layer 302 above an access layer 303. The core layer 301 serves as a gateway between the servers and the gaming devices. The core layer 301 is contemplated to be a so-called “back end” layer that resides in an administrative location, separate from the gaming floor, for example, and protected physically and electronically.

The distribution layer 302 serves to collect traffic between the core layer 301 and the access layer 303. The distribution layer may comprise trunks and switches that route message and signal traffic through the network. The access layer 303 provides a physical interface between the gaming machines (and any of their associated devices) and the rest of the network. In one preferred embodiment, this is done via managed switches.

In another aspect of a preferred embodiment, core layer 301 includes one or more servers that are coupled via a communication path to one or more switches. In one embodiment, the servers and switches of the core layer 301 are located within the gaming establishment premises in a secure administrative area. The servers may, but are not required to be, game servers. The communication path may be hardwire (e.g., copper), fiber, wireless, microwave, or any other suitable communications path that may be protected from attack.

The distribution layer 302 communicates with the core layer 301 via high bandwidth communications links. These links may be copper, fiber, or any other suitable link. If desired, redundant links may be built into the system to provide more fail-safe operation. The communications links couple the core layer switches to the distribution layer switches.

In another aspect of a preferred embodiment, the distribution layer 302 communicates with the access layer 303 via a high capacity communication link. The link may be wire, fiber, wireless, or any other suitable communication link. In the embodiment, the communication link is coupled to a gaming carousel that comprises a plurality of gaming machines. A managed switch is coupled to the link to provide an interface switch to a plurality of other managed switches.

In one embodiment of the gaming network, the network uses TCP/IP sessions between the gaming machines and the servers. The TCP/IP sessions are used to exchange private information concerning game operations, game performance, network management, patron information, revised game code, accounting information, and other sensitive information. In one embodiment, sessions may be a single message and acknowledgement, or the sessions may be an extended interactive, multiple transaction session. Other instantiations may include UDP/IP, token ring, MQ, and the like.

Moreover, the gaming network may use a number of network services for administration and operation. Dynamic Host Configuration Protocol (DHCP) allows central management and assignment of IP addresses within the gaming network. The dynamic assignment of IP addresses is used in one embodiment instead of statically assigned IP addresses for each network component. A DNS (domain name service) is used to translate between the domain names
and the IP addresses of network components and services. DNS servers are well known in the art and are used to resolve the domain names to IP addresses on the Internet.

[0141] Similarly, Network Time Protocol (NTP) is used to synchronize time references within the network components for security and audit activities. It is important to have a consistent and synchronized clock so that the order and the timing of transactions within the gaming network can be known with reliability and certainty. Network information can be gathered centrally at a single workstation by using the Remote Monitoring (RMON) protocol. SNMP (simple network management protocol) allows network management components to remotely manage hosts on the network, thus providing scalability. Still further, TFTP (trivial file transfer protocol) is used by servers to boot or download code to network components.

[0142] In one embodiment, the network may be implemented using the IPv6 protocol designed by the IETF (Internet Engineering Task Force). When using IPv6, the network may take advantage of the Quality of Service (QoS) features available with IPv6. QoS refers to the ability of a network to provide a guaranteed level of service (e.g., transmission rate, loss rate, minimum bandwidth, packet delay, and the like). QoS may be used as an additional security feature in that certain transactions may request a certain QoS as a rule or pursuant to some schedule.

[0143] Referring again to FIG. 5, in a preferred embodiment, all of the ports 230 are internal to the IP gaming hub 200, which ensures total control of the ports and a QoS (or other packet delivery prioritization technology) encoding mechanism 240. As identified above, the SDS data packets are programmatically encoded with a specific QoS high priority level (or other packet delivery prioritizing technology), while all of the other data packets are programmatically encoded with a lower priority level (e.g., zero) as the data passes into the downlink port (ingress) and moves to the uplink port (egress). This procedure ensures that the SDS data (or other specifically designated game accounting data) is encoded with a QoS high priority level (or other packet delivery prioritizing technology) at the inception of the packets on the network. Preferably, all of the other ports 230 are set to zero.

[0144] In another embodiment the QoS priority level of packets from the ingress ports may be programmatically encoded with a lower priority by hardware located at the egress port rather than by the switch hardware directly at the ingress ports. This allows the use of any available switching circuit whether or not it has the built-in capability of re-marking the priority of ingress packets.

[0145] In one preferred embodiment the configuration of the packet QoS encoding methodology in IP gaming hub 200 is administered through the use of an SNMP server located at the core layer of the network. This server allows on-the-fly adjustment of the encoding scheme to the devices that attach to the ports 230. This server may also be used as an access manager for devices attached to the ports 230 to make requests to be treated as high-priority traffic. In this implementation, a device that is authorized to transmit high-priority traffic but that is currently being treated as a low-priority device, may dynamically request that its data transmissions be re-prioritized to a different priority level.

[0146] In a preferred embodiment, as a result of the SDS data (or other specifically designated game accounting data) being encoded within the IP gaming hub 200, there is no possibility of personnel either intentionally or accidentally plugging cables into the incorrect ports 230, since all the cables plugging into the IP gaming hub 200 have the same priority (e.g. zero or other low priority). In one preferred embodiment of the IP gaming hub 200, the SDS data packets always go out first before any data from the ingress ports due to the QoS high packet delivery priority encoding that is implemented on the internal switch 220.

[0147] In a preferred embodiment, the uplink (or egress) port 230 of the IP gaming hub 200 connects to a QoS-enabled switch in a carousel. This internal switch 220 has the ability to take the data from its ingress ports 230 and move them to the egress port 230 (i.e., the uplink to the Distribution Layer devices), using QoS prioritizing techniques, thus ensuring that the high priority QoS-encoded packets are passed first. Having the controlled switch 220 located within the IP gaming hub 200 also provides the ability to extract other information from the controlled layer environment. For example, in some embodiments, the IP gaming hub 200 is capable of supplying information about the motherboard and other elements within the cabinet, as well as their relationship with the GPU.

[0148] In a preferred embodiment, the controlled ingress system built into the IP gaming hub 200 ensures that the SDS data packets on a shared Ethernet network have correct (e.g. high delivery priority) QoS encoding and ensures that the other ports in the cabinet are set to a standard best delivery encoding (e.g. zero or other low priority). This configuration also presents a suitable cabling configuration since multiple Ethernet ports 230 are accommodated within a cabinet. Accordingly, the multiple Ethernet ports 230 are all accommodated by the IP gaming hub 200 while having only a single wire leave the cabinet. In a preferred embodiment, the Ethernet switches that are utilized are QoS aware.

[0149] In one preferred embodiment, these Ethernet switches 220 are connected to a distribution switch in a nearby closet (or other suitable location) and use a QoS encoder 240 to ensure the high priority delivery of the SDS data. In one preferred embodiment, the distribution switch is set to “trust” and uses the QoS encoding that is conveyed by the uplink switch in the carousel. Using the QoS delivery prioritizing information supplied in the IP packets, the packets are moved from the ingress ports (all the carousel switches) to the egress port, which is preferably a gigabit Ethernet connection to the core switch, as shown in FIG. 6.

[0150] Referring now to the data flowing from the SDS servers 260 back to the game units, as shown in FIG. 6, the Core Layer switch preferably knows where the SDS servers are attached. Preferably, the switch is in a controlled IT area. In another aspect of one preferred embodiment, the QoS encoding is applied to any packets sent out from the SDS servers 260 and entering the core switch on their assigned port, thereby ensuring that the same delivery priority that is used on the incoming data from the SDS servers is replicated on any outgoing data.

[0151] In one preferred embodiment, the IP gaming hub 200 is an 802.1x enabled smart device (using extensible authentication protocol) that is intelligent enough to perform an 802.1x secure authentication procedure. 802.1x is a
methodology typically used for securing a carousel switch (i.e., locking down the switch), so that only allow approved devices can access a port on the switch. Specifically, 802.1x is an IEEE standard for network access control. 802.1x keeps a network port disconnected until authentication is completed. Depending on the results, the port is either made available to the user, or the user is denied access to the network.

802.1x provides an authentication framework, allowing a user to be authenticated by a central authority. 802.1x uses an existing protocol, the Extensible Authentication Protocol (EAP, RFC 2284), that works on Ethernet, Token Ring, or wireless LANs, for message exchange during the authentication process. The device that contains usernames and passwords and authorizes the access-requesting device is the "authentication server." The authentication server may use the Remote Authentication Dial-In User Service (RADIUS), although 802.1x does not require it.

Although the invention has been described in language specific to computer structural features, methodological acts, and by computer-readable media, it is to be understood that the invention defined in the appended claims is not necessarily limited to the specific structures, acts, or media described. Therefore, the specific structural features, acts, and mediums are disclosed as exemplary embodiments implementing the claimed invention.

Furthermore, the various embodiments described above are provided by way of illustration only and should not be construed to limit the invention. Those skilled in the art will readily recognize various modifications and changes that may be made to the claimed invention without following the example embodiments and applications illustrated and described herein, and without departing from the true spirit and scope of the claimed invention, which is set forth in the following claims.

What is claimed is:

1. A controlled access device for producing a controlled access layer in a packet switching environment, the device comprising:
   a. a game monitoring device;
   b. a plurality of Ethernet ports for transmitting data packets, wherein the plurality of Ethernet ports are connectable to a distribution switch;
   c. an internal switch, wherein the internal switch forwards transmitted data packets from one or more ingress ports to an egress port; and
   d. an encoding mechanism, wherein the encoding mechanism encodes a first type of data packets with a QoS high packet delivery priority, and wherein the encoding mechanism encodes a second type of data packets with a QoS lower packet delivery priority.

2. The system of claim 1, wherein the first type of data packets comprise casino game accounting data packets.

3. The device of claim 1, wherein the first type of data packets comprise non-casino game accounting data packets.

4. The device of claim 1, wherein the second type of data packets comprise Slot Data Systems data packets.

5. The device of claim 1, wherein the second type of data packets comprise non-Slot Data Systems data packets.

6. The device of claim 1, wherein the packet delivery priority is controlled at an ingress level.

7. The device of claim 1, wherein the data packets are encoded with packet delivery priority information at the inception of the packets on the network.

8. The device of claim 1, wherein the encoded packet delivery priority information enables guaranteed latency levels.

9. The device of claim 1, wherein the system utilizes asynchronous transfer mode.

10. The device of claim 1, wherein internal switch is not controlled by port location.

11. The device of claim 1, wherein all of the first type of data packets are forwarded before any of the second type of data packets are forwarded.

12. The device of claim 1, wherein the first type of data packets are generated by the controlled access device.

13. The device of claim 1, wherein the second type of data packets are received through the ingress ports.

14. The device of claim 1, wherein the internal switch enables QoS packet delivery priority information to be filtered and changed, thereby preventing the second type of data packets which arrive through the ingress ports from having an unacceptable QoS high packet delivery priority encoding after passing through the switch.

15. The device of claim 1, wherein the device utilizes an 802.1x secure authentication procedure.

16. The device of claim 1, wherein the device enables real time adjustment from a remote location of the packet delivery priority encoded onto different data types by the device.

17. A controlled access system for producing a controlled access layer in a packet switching environment, the system comprising:

   a. a game monitoring system;
   b. a plurality of Ethernet ports for transmitting data packets, wherein the plurality of Ethernet ports include at least one ingress port and at least one egress port;
   c. an internal switch, wherein the internal switch forwards transmitted data packets from at least one ingress port to at least one egress port; and
   d. an encoding system, wherein the encoding mechanism encodes a first type of data packets with a high packet delivery priority, and wherein the encoding mechanism encodes a second type of data packets with a lower packet delivery priority.

18. The system of claim 17, wherein the first type of data packets comprise casino game accounting data packets.

19. The system of claim 17, wherein the first type of data packets comprise Slot Data Systems data packets.

20. The system of claim 17, wherein the second type of data packets comprise non-casino game accounting data packets.

21. The system of claim 17, wherein the second type of data packets comprise non-Slot Data Systems data packets.

22. The system of claim 17, wherein the packet delivery priority is controlled at an ingress level.

23. The system of claim 17, wherein the data packets are encoded with packet delivery priority information at the inception of the packets on the network.
24. The system of claim 17, wherein the encoded packet delivery priority information enables guaranteed latency levels.

25. The system of claim 17, wherein the system utilizes asynchronous transfer mode.

26. The system of claim 17, wherein internal switch is not controlled by port location.

27. The system of claim 17, wherein all of the first type of data packets are forwarded before any of the second type of data packets are forwarded.

28. The system of claim 17, wherein the second type of data packets are received through the ingress ports.

29. The system of claim 17, wherein the internal switch enables packet delivery priority information to be filtered and changed, thereby preventing the second type of data packets which arrive through the ingress ports from having an unacceptable high packet delivery priority encoding after passing through the switch.

30. The system of claim 17, wherein the system utilizes an 802.1x secure authentication procedure.

31. The system of claim 17, wherein the system enables real time adjustment from a remote location of the packet delivery priority encoded onto different data types by the system.

32. The method of producing a controlled access layer in a casino gaming environment using a controlled access device that includes a game monitoring device, a plurality of Ethernet ports, and an internal switch, the method comprising:

receiving data packets through at least one ingress port;

identifying game accounting data packets, if present, and identifying non-game accounting data packets, if present;

encoding the game accounting data packets with a high packet delivery priority, and the encoding the non-game accounting data packets with a lower packet delivery priority; and

forwarding the encoded data packets through an egress port.

34. The method of claim 33, wherein the game accounting data packets comprise casino game accounting data packets.

35. The method of claim 33, wherein the non-game accounting data packets comprise Slot Data Systems data packets.

36. The method of claim 33, wherein the non-game accounting data packets comprise non-casino game accounting data packets.

37. The method of claim 33, wherein the non-game accounting data packets comprise non-Slot Data Systems data packets.

38. The method of claim 33, wherein the packet delivery priority is controlled at an ingress level.

39. The method of claim 33, wherein the data packets are encoded with packet delivery priority information at the inception of the packets on the network.

40. The method of claim 33, wherein the encoded packet delivery priority information enables guaranteed latency levels.

41. The method of claim 33, wherein the method utilizes asynchronous transfer mode.

42. The method of claim 33, wherein internal switch is not controlled by port location.

43. The method of claim 33, wherein all of the game accounting data packets are forwarded before any of the non-game accounting data packets are forwarded.

44. The method of claim 33, wherein game accounting data packets are generated by the controlled access device.

45. The method of claim 33, wherein non-game accounting data packets are received through the ingress ports.

46. The method of claim 33, wherein the internal switch enables packet delivery priority information to be filtered and changed, thereby preventing the non-game accounting data packets which arrive through the ingress ports from having a high packet delivery priority encoding after passing through the switch.

47. The method of claim 33, further comprising: utilizing an 802.1x secure authentication procedure.

48. The method of claim 33, further comprising: enabling real time adjustment from a remote location of the packet delivery priority encoded onto different data types.

49. A method for producing a controlled access layer in a packet switching environment using a controlled access device that includes a game monitoring device, a plurality of Ethernet ports, and an internal switch, the method comprising:

implementing an 802.1x secure authentication procedure in the controlled access device;

receiving data packets through at least one ingress port;

identifying a first type of data packets, if present, and identifying a second type of data packets, if present;

encoding the first type of data packets with a high packet delivery priority, and the encoding the second type of data packets with a lower packet delivery priority; and

forwarding the encoded data packets through an egress port.

50. The method of claim 49, wherein the first type of data packets comprise casino game accounting data packets.

51. The method of claim 49, wherein the first type of data packets comprise Slot Data Systems data packets.

52. The method of claim 49, wherein the second type of data packets comprise non-casino game accounting data packets.

53. The method of claim 49, wherein the second type of data packets comprise non-Slot Data Systems data packets.

54. The method of claim 49, wherein the packet delivery priority is controlled at an ingress level.

55. The method of claim 49, wherein the data packets are encoded with packet delivery priority information at the inception of the packets on the network.

56. The method of claim 49, wherein the encoded packet delivery priority information enables guaranteed latency levels.

57. The method of claim 49, wherein the method utilizes asynchronous transfer mode.

58. The method of claim 49, wherein internal switch is not controlled by port location.

59. The method of claim 49, wherein all of the game accounting data packets are forwarded before any of the non-game accounting data packets are forwarded.
60. The method of claim 49, wherein game accounting data packets are generated by the controlled access device.

61. The method of claim 49, wherein non-game accounting data packets are received through the ingress ports.

62. The method of claim 49, wherein the internal switch enables packet delivery priority information to be filtered and changed, thereby preventing the non-game accounting data packets which arrive through the ingress ports from having a high packet delivery priority encoding after passing through the switch.

63. The method of claim 49, further comprising: enabling real time adjustment from a remote location of the packet delivery priority encoded onto different data types.

64. A controlled access system for producing a controlled access layer in a packet switching environment over a casino gaming network, the system comprising:

a game monitoring system, wherein the game monitoring system monitors and manages casino game accounting data, and wherein the game monitoring system connects internal components of a casino game to the casino gaming network via the controlled access system;

a plurality of Ethernet ports, wherein the plurality of Ethernet ports transmits casino game accounting data, and wherein the plurality of Ethernet ports include at least one ingress port and at least one egress port;

an internal switch, wherein the internal switch forwards transmitted data packets from at least one ingress port to at least one egress port; and

an encoding mechanism that generates casino game accounting data packets, encodes a casino game accounting data packets with a high packet delivery priority, and encodes a non-casino game accounting data packets with a lower packet delivery priority.

65. A controlled access system for producing a controlled access layer in a packet switching environment, the system comprising:

a plurality of Ethernet ports for transmitting data packets, wherein the plurality of Ethernet ports include at least one ingress port and at least one egress port, and wherein the system utilizes an 802.1x secure authentication procedure;

an internal switch, wherein the internal switch forwards transmitted data packets from at least one ingress port to at least one egress port; and

an encoding system, wherein the encoding mechanism encodes a first type of data packets with a high packet delivery priority, and wherein the encoding mechanism encodes a second type of data packets with a lower packet delivery priority.
