The stretch of rail comprises a railway switch element (12) made from high-alloy steel, in which at least one alloy element has a content equal to at least 5% by weight, and a length of rail (14) made from steel, connected to one another by a weld without deposition of metal. The length of rail (14) is formed from a medium-alloy low-carbon steel of which the carbon content is less than 0.55% by weight.

FIG. 4
WELDING OF AN ELEMENT OF A TRACK UNIT
AND A RAIL SECTION WITHOUT ADDING ANY
MATERIAL

[0001] The present invention relates to a stretch of rail of
the type comprising a railway switch element made from
high-alloy steel, in which at least one alloy element has a
content equal to at least 5% by weight, and a length of steel
rail, connected to one another by a weld without deposition
of metal.

[0002] The invention relates in particular to the connection
between a switch such as a crossing frog and a section of rail
consisting for example of a running line rail made from
carbon steel.

[0003] It is known that, when a part made from carbon
steel is welded to a part made from high-alloy steel the
fusion produced during this operation causes, at the interface
between the two parts, the formation of alloys of which the
chemical composition is different from that of the basic
materials. When the welding is done without deposition of
metal, for example by flash welding, it is difficult to control
the nature of the alloys created. Therefore, the weld pro-
duced is generally of mediocre quality, rather more like
substration.

[0004] The carbon rails currently used to make the rails of
running lines include a quantity of carbon of between 0.55%
and 0.8% by weight. In order to ensure a sufficient hardness,
the rails have additions of other metals such as chromium.
However, the high quantity of chromium makes welding
impossible between two steels which are too highly alloyed.

[0005] In order to solve the problem mentioned above, it
is known to provide an insert forming an intermediate part
between the railway switch element made from high-alloy
steel and the length of rail. This intermediate part is formed
from a material capable of being welded easily onto the
railway switch element on the one hand and onto the length
of rail on the other hand.

[0006] The use of such an intermediate part increases the
cost of implementing the connection process, particularly
because of the specific characteristics of the material form-
ing the insert and the necessity of providing two welds.
Moreover, falls in hardness are observed in the length of rail,
in the zone heat-affected by the energy of the welding.

[0007] The object of the invention is to propose a solution
which makes it possible to ensure a satisfactory level of
hardness of the switch element and of the length of rail, and
also of the connection between the switch element and the
length of rail, without increasing the cost of producing the
connection between them.

[0008] To this end, the invention relates to a stretch of rail
of the aforementioned type, characterised in that the length
of rail is formed from a low-carbon steel in which the carbon
content is less than 0.55% by weight.

[0009] According to particular embodiments, the stretch
of rail has one or more of the following characteristics:

[0010] the length of rail is formed from a low-carbon steel
of which the medium-alloy carbon content is less than 0.5%
by weight;

[0011] the medium-alloy low-carbon steel forming the
length of rail is a bainitic steel;

[0012] the medium-alloy low-carbon steel forming the
length of rail has the following composition by weight:

[0013] 0.05% to 0.50% of carbon;
[0014] 0.5% to 2.5% of manganese;
[0015] 0.6% to 3% of silicon or aluminium;
[0016] 0.25% to 3.1% of chromium; and
[0017] 0% to 0.9% of molybdenum;

[0018] the medium-alloy low-carbon steel forming the
length of rail has a composition defined below:

[0019] 0.28% to 0.36% of carbon;
[0020] 1.40% to 1.70% of manganese;
[0021] at most 0.03% of phosphorus;
[0022] 0.01% to 0.03% of sulphur;
[0023] at most 0.005% of aluminium;
[0024] 1% to 1.40% of silicon;
[0025] 0.40% to 0.60% of chromium;
[0026] 0.08% to 0.20% of molybdenum;
[0027] at most 0.04% of titanium; and
[0028] at most 0.004% of boron; and

[0029] the railway switch element made from high-alloy
steel comprises 12% to 14% by weight of manganese.

[0030] The invention will be better understood by reading
the description which follows, given solely by way of
example and with reference to the drawings, in which:

[0031] FIG. 1 is a schematic view in elevation of a railway
track crossing frog to which four lengths of running line rail
are welded;

[0032] FIG. 2 is a photomicrograph of a weld of a stretch
of rail according to the invention; and

[0033] FIGS. 3 and 4 are diagrams showing the hardness
measured along the length of the stretch of rail in the region
of the weld for two different embodiments of the invention.

[0034] FIG. 1 shows a crossing frog which permits the
crossing of two intersecting stretches of track. Thus the
crossing frog 12 is connected at its four ends to four lengths
of running line 14.

[0035] The lengths of line 14 are connected to the frog by
welds 16 without deposition of metal.

[0036] As is known per se, the crossing frog 12 is formed
from a high-alloy steel, particularly a steel in which at least
one alloy element has a content equal to at least 5% by
weight.

[0037] This steel is in particular an alloyed steel contain-
ing between 12% and 14% by weight of manganese, the
crossing frog having been produced by moulding. This is a
steel which is well known under the name of HADFIELD.

[0038] The hardness of this steel is between 170 and 230
HB.

[0039] According to the invention, the lengths of rail 14
are made from a medium-alloy low-carbon steel of which the
carbon content is less than 0.55% by weight, and each
weld 16 is a weld without deposition of metal produced directly between the high-alloy steel and the medium-alloy low-carbon steel. The carbon content of the medium-alloy low-carbon steel is preferably less than 0.5% by weight.

[0040] The medium-alloy low-carbon steel is preferably a bainitic steel without carbide.

[0041] The low-carbon bainitic steel forming the length of rail 14 has advantageously the following composition by weight:

- [0042] 0.05% to 0.50% of carbon;
- [0043] 0.5% to 2.5% of manganese;
- [0044] 0.6% to 3% of silicon or aluminium;
- [0045] 0.25% to 3.1% of chromium; and
- [0046] 0% to 0.9% of molybdenum.

[0047] Even more preferably, the bainitic steel has a composition defined below:

- [0048] 0.28% to 0.36% of carbon;
- [0049] 1.40% to 1.70% of manganese;
- [0050] at most 0.03% of phosphorus;
- [0051] 0.01% to 0.03% of sulphur;
- [0052] at most 0.005% of aluminium;
- [0053] 1% to 1.40% of silicon;
- [0054] 0.40% to 0.60% of chromium;
- [0055] 0.08% to 0.20% of molybdenum;
- [0056] at most 0.04% of titanium; and
- [0057] at most 0.004% of boron.

[0058] This steel has a hardness of between 350 and 390 HB.

[0059] The weld 16 is obtained for example by flash welding and forging according to a conventional welding cycle which is known per se.

[0060] As a variant, the weld can be obtained by induction, by friction, by electron beams, by laser or by any other high-energy beam.

[0061] The appearance of the weld 16 which is obtained is illustrated in FIG. 2. On this microphotograph which is enlarged five hundred times it appears that the interface is very neat between the low-carbon bainitic steel and the high-alloy steel, the two steels being interpenetrated in a satisfactory manner.

[0062] According to a first embodiment which is envisaged, the switch element made from high-alloy steel is at ambient temperature before the flash welding and has a hardness resulting from re-annealing of 170 to 230 HB.

[0063] In this case the development of the hardness of the stretch of rail in the vicinity of the weld is shown in FIG. 3.

[0064] It is observed that, in its running part, the length of rail 14 has a hardness of between 290 and 330 HB and that this hardness increases to reach a value close to 380 HB in the immediate vicinity of the weld. The hardness of the stretch of rail remains at a value of between 185 and 235 HB in the switch element 12 made from high-alloy steel. This hardness corresponds to the hardness of the switch element before welding.

[0065] Therefore it is observed that with the compositions according to the invention the hardness remains satisfactory in the immediate vicinity of the weld, and is not less than the hardness specific to the two elements which are welded to one another, and that in particular there is no drop in the hardness in the heat-affected zone (HAZ).

[0066] According to a variant, the end of the switch element made from high-alloy steel which is intended to be welded is pre-hardened before the flash welding is carried out in order to increase its hardness. This pre-hardening is obtained for example by explosion.

[0067] Thus the hardness of the switch element before welding is brought to a value of between 330 and 360 HB.

[0068] With this additional step, the measurements of hardness obtained are those illustrated in FIG. 4. In this case, the hardness of the length of rail is substantially identical to that of FIG. 3. By contrast, the hardness of the switch element made from high-alloy steel in the immediate vicinity of the weld is substantially equal to 350 HB, a value substantially equal to that of the length of rail in its running portion.

1. Stretch of rail comprising a railway switch element (12) made from high-alloy steel, in which at least one alloy element has a content equal to at least 5% by weight, and a length of rail (14) made from medium-alloy steel, directly connected to one another by a weld without deposition of metal, characterised in that the length of rail (14) is formed from a medium-alloy low-carbon steel in which the carbon content is less than 0.55% by weight.

2. Stretch of rail as claimed in claim 1, characterised in that the length of rail (14) is formed from a medium-alloy low-carbon steel in which the carbon content is less than 0.5% by weight.

3. Stretch of rail as claimed in claim 1, characterised in that medium-alloy low-carbon steel forming the length of rail is a bainitic steel.

4. Stretch of rail as claimed in claim 3, characterised in that medium-alloy low-carbon steel forming the length of rail is a bainitic steel.

5. Stretch of rail as claimed in claim 1, characterised in that medium-alloy low-carbon steel forming the length of rail has the following composition by weight:

- 0.05% to 0.50% of carbon;
- 0.5% to 2.5% of manganese;
- 0.6% to 3% of silicon or aluminium;
- 0.25% to 3.1% of chromium; and
- 0% to 0.9% of molybdenum.

6. Stretch of rail as claimed in claim 5, characterised in that medium-alloy low-carbon steel forming the length of rail has a composition defined below:

- 0.28% to 0.36% of carbon;
- 1.40% to 1.70% of manganese;
- at most 0.03% of phosphorus;
0.01% to 0.03% of sulphur; at most 0.005% of aluminium; at most 0.04% of titanium; and at most 0.004% of boron.

7. Stretch of rail as claimed in claim 1, characterised in that the railway switch element made from high-alloy steel comprises 12% to 14% by weight of manganese.
