An integrated circuit comprises a temperature sensor that senses a temperature of the integrated circuit. A memory module stores oscillator data relating to calibrations and selects one of the oscillator calibrations as a function of the sensed temperature. An oscillator module generates a reference signal having a frequency. A phase locked loop module comprises a feedback loop having a feedback loop parameter. The phase locked loop module selectively adjusts the feedback loop parameter based on the selected one of the oscillator calibrations.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application is a Continuation of U.S. patent application Ser. No. 11/328,979 filed Jan. 10, 2006, which claims the benefit of U.S. Provisional Application Nos. 60/756,828, filed Jan. 6, 2006, 60/714,454, filed on Sep. 6, 2005, and 60/730,568, filed on Oct. 27, 2005, and is a continuation-in-part of U.S. patent application Ser. No. 10/892,709, filed on Jul. 16, 2004, which is a continuation in part of U.S. patent application Ser. No. 10/272,247, filed on Oct. 15, 2002, the contents of which are hereby incorporated by reference in their entirety.

TECHNICAL FIELD

[0002] This invention relates to integrated circuits, and more particularly to integrated circuits with annealed glass paste arranged on a silicon wafer.

BACKGROUND

[0003] Precision frequency references are required in many types of electronic devices such as cellular phones and other handheld devices. Crystal oscillators are typically used to provide the precision frequency reference in these electronic devices. However, crystal oscillators have several inherent disadvantages including large bulky size, fragility, and high cost. In addition, the size and cost of crystal oscillators is related to the resonant frequency so that as the frequency increases, the size decreases, and the cost and fragility may rapidly increase. As the size of electronic devices continues to decrease, the use of crystal oscillators becomes more problematic due to the size, fragility, and cost limitations.

[0004] Semiconductor oscillators have been a poor alternative to crystal oscillators and are generally unsuitable for use as a precision frequency reference due to excessive variation in the oscillating frequency, especially with changes in temperature.

SUMMARY OF THE INVENTION

[0005] An integrated circuit (IC) package comprises a IC wafer and an annealed glass paste (AGP) layer that is arranged adjacent to the IC wafer.

[0006] In other features, a molding material encapsulates at least part of the IC wafer and the AGP layer. The AGP layer is arranged on at least one side of the IC wafer. The AGP layer is arranged on a plurality of disjoint areas on at least one side of the IC wafer. A layer of a conductive material that is arranged on a portion of the AGP layer.

[0007] In other features, the IC wafer comprises a circuit component arranged in the IC wafer. The AGP layer is arranged between the circuit component and the molding material. The circuit component comprises at least one of an oscillator and an inductor. The inductor comprises a spiral inductor. The molding material encapsulates a portion of the IC wafer. The AGP layer comprises a glass frit. The AGP layer is arranged adjacent to the IC wafer using one of a screen printing, dipping and masking.

[0008] In other features, the conductive material comprises one of a conductive epoxy and a conductive epoxy paint. The layer of the conductive material is arranged on the AGP layer by dipping the IC package in a container containing the conductive material.

[0009] An integrated circuit comprises a temperature sensor that senses a temperature of the integrated circuit. A memory module stores data relating to oscillator calibrations and selects one of the oscillator calibrations as a function of the sensed temperature. An oscillator module generates a reference signal having a frequency. A phase locked loop module includes a feedback loop having a feedback loop parameter and selectively adjusts the feedback loop parameter based on the selected one of the oscillator calibrations.

[0010] In other features, the phase locked loop module comprises a fractional phase locked loop and the feedback loop parameter is a ratio of a scaling factor. The fractional phase locked loop comprises a phase frequency detector module that communicates with the oscillator module and that receives the reference frequency. A charge pump module communicates with the phase frequency detector module. A voltage controlled oscillator module communicates with the charge pump module and generates an output frequency. A scaling module communicates with the voltage controlled oscillator module and the phase frequency detector module, selectively adjusts the output frequency based on first and second scaling factors, and adjusts a ratio of the first and second scaling factors based on the selected one of the oscillator calibrations.

[0011] In other features, the first and second scaling factors are divisors equal to N and N+1, wherein N is an integer greater than zero. The phase locked loop module comprises a Sigma Delta fractional phase locked loop module and the feedback loop parameter includes modulation of a scaling divider. The Sigma Delta fractional phase locked loop module comprises a phase frequency detector module that communicates with the oscillator module and that receives the reference frequency. A charge pump module communicates with the phase frequency detector module. A voltage controlled oscillator module communicates with the charge pump module and that generates an output frequency. A scaling module communicates with the voltage controlled oscillator module and the phase frequency detector module and selectively divides the output frequency by first and second scaling factors. A Sigma Delta modulator adjusts modulation of the scaling module between the first and second scaling factors based on the selected one of the oscillator calibrations. The first and second scaling factors are divisors equal to N and N+1, where N is an integer greater than zero.

[0012] An integrated circuit comprises temperature sensing means for sensing a temperature of the integrated circuit. Memory means for storing data relating to oscillator calibrations and for selecting one of the oscillator calibrations as a function of the sensed temperature. Oscillating means generates a reference signal having a frequency based on the oscillator calibrations. Phase locked loop means, that includes a feedback loop having a feedback loop parameter, selectively adjusts the feedback loop parameter based on the selected one of the oscillator calibrations.

[0013] In other features, the phase locked loop means comprises a fractional phase locked loop and the feedback
loop parameter is a ratio of a scaling factor. The fractional phase locked loop comprises phase frequency detector means, that communicates with the oscillating means, for receiving the reference frequency. Charge pump means generates voltage and communicates with the phase frequency detector means. Voltage controlled oscillator means, that communicates with the charge pump means, generates an output frequency. Scaling means, that communicates with the voltage controlled oscillator means and the phase frequency detector means, selectively adjusts the output frequency based on first and second scaling factors and adjusts a ratio of the first and second scaling factors based on the selected one of the oscillator calibrations.

[0014] In other features, the first and second scaling factors are divisors equal to N and N+1, and wherein N is an integer greater than zero. The phase locked loop means comprises a Sigma Delta fractional phase locked loop and the feedback loop parameter includes modulation of a scaling divisor. The Sigma Delta fractional phase locked loop comprises phase frequency detector means, that communicates with the oscillator means, for receiving the reference frequency. Charge pump means generates a voltage and communicates with the phase frequency detector means. Voltage controlled oscillator means, that communicates with the charge pump means, generates an output frequency. Scaling means, that communicates with the voltage controlled oscillator means and the phase frequency detector means, selectively divides the output frequency by first and second scaling factors. Sigma Delta modulating means adjusts modulation of the scaling means between the first and second scaling factors based on the selected one of the oscillator calibrations. The first and second scaling factors are divisors equal to N and N+1, where N is an integer greater than zero.

[0015] A method for operating an integrated circuit comprises sensing a temperature of the integrated circuit; storing data relating to oscillator calibrations; selecting one of the oscillator calibrations as a function of the sensed temperature; generating a reference signal having a frequency based on the oscillator calibrations; and selectively adjusting a feedback loop parameter of a phase locked loop based on the selected one of the oscillator calibrations.

[0016] In other features, the phase locked loop comprises a fractional phase locked loop and the feedback loop parameter is a ratio of a scaling factor. The phase locked loop comprises a Sigma Delta fractional phase locked loop and the feedback loop parameter includes modulation of a scaling divisor.

[0017] An integrated circuit package comprises an integrated circuit that comprises a temperature sensor that senses a temperature of the integrated circuit. A memory module stores data relating to oscillator calibrations and that selects one of the oscillator calibrations as a function of the sensed temperature. An oscillator module generates a reference signal having a frequency that is based on the selected one of the oscillator calibrations. A packaging material encases at least part of the integrated circuit and has a low dielectric loss.

[0018] In other features, the packaging material includes at least one material selected from a group consisting of polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluorooalkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging material includes a low dielectric loss plastic.

[0019] An integrated circuit package comprises an integrated circuit that comprises an oscillator module that generates a reference signal having a frequency that is based on one of a plurality of oscillator calibration settings. A packaging material encases at least part of the integrated circuit and has a low dielectric loss.

[0020] In other features, the integrated circuit further comprises a temperature sensor that senses a temperature of the integrated circuit. A memory module stores the oscillator calibration settings. The packaging material includes at least one material selected from a group consisting of polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluorooalkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging material includes a low dielectric loss plastic.

[0021] A method for providing an integrated circuit package comprises providing an integrated circuit; encasing the integrated circuit in a packaging material that has a low dielectric loss; sensing a temperature of the integrated circuit during operation; storing data relating to oscillator calibrations; selecting one of the oscillator calibrations as a function of the sensed temperature; and generating a reference signal having a frequency that is based on the selected one of the oscillator calibrations.

[0022] In other features, the packaging material includes at least one material selected from a group consisting of polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluorooalkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging material includes a low dielectric loss plastic.

[0023] A method for providing an integrated circuit package comprises providing an integrated circuit; selecting one of a plurality of oscillator calibration settings; generating a reference signal having a frequency that is based on one of the plurality of oscillator calibration settings; and encasing the integrated circuit in a packaging material that has a low dielectric loss.

[0024] In other features, the method comprises sensing a temperature of the integrated circuit; and selecting the one of the plurality of oscillator calibration settings based on the sensed temperature. The packaging material includes at least one material selected from a group consisting of polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluorooalkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging material includes a low dielectric loss plastic.

[0025] An integrated circuit package comprises an integrated circuit that comprises temperature sensing means for sensing a temperature of the integrated circuit. Storing means stores data relating to oscillator calibrations and for selecting one of the oscillator calibrations as a function of the sensed temperature. Oscillating means generates a reference signal having a frequency that is based on the selected one of the oscillator calibrations. Packaging means encases at least part of the integrated circuit and has a low dielectric loss.

[0026] In other features, the packaging means includes at least one material selected from a group consisting of...
polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluoralkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging means includes a low dielectric loss plastic.

[0027] An integrated circuit package comprises an integrated circuit that comprises oscillating means for generating a reference signal having a frequency that is based on one of a plurality of oscillator calibrations settings and packaging means for encasing at least part of the integrated circuit and having a low dielectric loss.

[0028] In other features, the integrated circuit further comprises temperature sensing means for sensing a temperature of the integrated circuit. Storing means stores oscillator calibration data. The packaging means includes at least one material selected from a group consisting of polychlorotrifluoroethylene, fluorinated ethylene propylene copolymer, perfluoralkoxy, and a copolymer of ethylene and tetrafluoroethylene. The packaging means includes a low dielectric loss plastic.

[0029] An integrated circuit package comprises an integrated circuit that comprises a temperature sensor that senses a temperature of the integrated circuit and a memory module that stores oscillator calibrations and that selects one of the oscillator calibrations as a function of the sensed temperature. An oscillator module generates a reference signal having a frequency that is based on the selected one of the oscillator calibrations. An epoxy layer adheres a glass layer to the integrated circuit. A packaging material encases at least part of the glass layer and the integrated circuit.

[0030] In other features, the glass layer is located between adjacent to portions of the integrated circuit that include the oscillator module. The oscillator module includes an on-chip inductor and wherein the glass layer is located adjacent to portions of the integrated circuit that include on-chip inductor. The glass layer includes a cavity that defines an air gap and wherein the cavity is adjacent to portions of the integrated circuit that include the oscillator module. The glass layer includes a cavity that defines an air gap and wherein the cavity is adjacent to portions of the integrated circuit that include an inductor of the oscillator module.

[0031] An integrated circuit package comprises an integrated circuit that comprises temperature sensing means for sensing a temperature of the integrated circuit and storing means for storing oscillator calibrations and for selecting one of the oscillator calibrations as a function of the sensed temperature. Oscillating means generates a reference signal having a frequency that is based on the selected one of the oscillating means calibrations. Means attaches a glass layer to the integrated circuit. Packaging means encases at least part of the glass layer and the integrated circuit.

[0032] In other features, the glass layer is located adjacent to portions of the integrated circuit that include the oscillating means. The oscillating means includes an on-chip inductor and wherein the glass layer is located adjacent to portions of the integrated circuit that include on-chip inductor. The glass layer includes a cavity that defines an air gap and wherein the cavity is adjacent to portions of the integrated circuit that include the oscillating means. The glass layer includes a cavity that defines an air gap and wherein the cavity is adjacent to portions of the integrated circuit that include an inductor of the oscillating means.

[0033] A method for providing an integrated circuit package comprises sensing a temperature of an integrated circuit; storing oscillator calibrations; selecting one of the oscillator calibrations as a function of the sensed temperature; generating a reference signal having a frequency that is based on the selected one of the oscillator calibrations; and attaching a glass layer to the integrated circuit and encasing at least part of the glass layer and the integrated circuit in a packaging material.

[0034] In other features, the method includes locating the glass layer adjacent to portions of the integrated circuit that include the oscillator module. The oscillator module includes an on-chip inductor and further comprising locating the glass layer adjacent to portions of the integrated circuit that include on-chip inductor. The glass layer includes a cavity that defines an air gap and further comprising locating the cavity adjacent to portions of the integrated circuit that include the oscillator. The glass layer includes a cavity that defines an air gap and further comprising locating the cavity adjacent to portions of the integrated circuit that include an inductor of the oscillator.

[0035] An integrated circuit (IC) package comprises an IC wafer. A first portion is arranged adjacent to the IC wafer. A second portion is arranged adjacent to the IC wafer and is spaced from the first portion. The first and second portions comprise at least one of an annular glass paste (AGP) and epoxy. A layer is arranged adjacent to the first and second portions and creates an air gap between the layer, the first and second portions and the IC wafer.

[0036] In other features, the IC wafer comprises a silicon wafer. A molding material encapsulates at least part of the IC wafer, the layer and the first and second portions. The layer comprises at least one of glass and silicon. A conductive material is arranged adjacent to the first and second portions. The silicon wafer comprises a circuit component. The air gap is arranged between the circuit component, the layer and the first and second portions. The circuit component comprises at least one of an oscillator and an inductor. The inductor comprises a spiral inductor.

[0037] In other features, the first and second portions comprise glass frit. The first and second portions are applied to the silicon wafer using one of a screen printing, dipping and masking. The conductive material comprises one of a conductive epoxy and conductive epoxy paint. The conductive material is applied to the first and second portions by dipping the at least part of the IC package in a container containing the conductive material. The layer has a first width that is less than a second width of the silicon wafer. The IC wafer comprises bond pads. The layer has a first width that is less than a second width of the silicon wafer and further comprising bond pads that are located in an outer region of the silicon wafer.

[0038] A method of providing an integrated circuit (IC) package comprises providing an IC wafer; arranging a first portion adjacent to the IC wafer; arranging a second portion adjacent to the IC wafer and spaced from the first portion, wherein the first and second portions comprise at least one of an annular glass paste (AGP) and epoxy; and arranging a layer adjacent to the first and second portions, wherein the layer creates an air gap between the layer, the first and second portions and the IC wafer.

[0039] In other features, the IC wafer comprises a silicon wafer. The method further includes encapsulating at least
part of the IC wafer, the layer and the first and second portions. The layer comprises at least one of glass and silicon. The method further includes arranging a conductive material adjacent to the first and second portions. The method further includes arranging the air gap between the circuit component, the layer and the first and second portions. The circuit component comprises at least one of an oscillator and an inductor. The method further includes arranging a conductive layer between the layer and the first and second portions. The method further includes applying the first and second portions to the silicon wafer using one of a screen printing, dipping and masking. The conductive material comprises one of a conductive epoxy and conductive epoxy paint. The layer has a first width that is less than a second width of the silicon wafer. The method further includes providing bond pads on the IC wafer in an outer region of the silicon wafer.

An integrated circuit (IC) package comprises an IC wafer comprising a circuit and a “C”-shaped layer that is arranged adjacent to the substrate and that creates an air gap between the “C”-shaped layer and the circuit of the IC wafer.

In other features, a molding material that encapsulates at least part of the IC wafer and the “C”-shaped layer. The “C”-shaped layer comprises at least one of glass and silicon. The circuit component comprises at least one of an oscillator and an inductor. The inductor comprises a spiral inductor.

A method for providing an integrated circuit (IC) package comprises providing an IC wafer comprising a circuit and arranging a “C”-shaped layer adjacent to the substrate, wherein the “C”-shaped layer creates an air gap between the “C”-shaped layer and the circuit of the IC wafer.

In other features, the method includes encapsulating at least part of the IC wafer and the “C”-shaped layer. The “C”-shaped layer comprises at least one of glass and silicon. The circuit component comprises at least one of an oscillator and an inductor. The inductor comprises a spiral inductor.

Further areas of applicability of the present invention will become apparent from the detailed description provided hereinafter. It should be understood that the detailed description and specific examples, while indicating the preferred embodiment of the invention, are intended for purposes of illustration only and are not intended to limit the scope of the invention.

DETAILED DESCRIPTION

FIG. 1 shows an aspect of a crystal oscillator emulator 10 for generating an output signal 12 having a precise frequency. The crystal oscillator emulator 10 may be constructed on a single semiconductor die using any process including a Complementary-Metal-Oxide-Semiconductor (CMOS) process.

The crystal oscillator emulator 10 may include a semiconductor oscillator 14 to generate the output signal 12. Any type of semiconductor oscillator may be used including LC oscillators, RC oscillators, and ring oscillators. The semiconductor oscillator 12 includes a control input 16 to vary the frequency of the output signal. The control input 16 may be any electrical input that effects a controlled change in the output signal frequency such as the supply voltage of a ring oscillator and a voltage input to a varactor of an LC oscillator.

A non-volatile memory 18 includes calibration information 20 for controlling the output signal frequency as a function of temperature. Any type of non-volatile memory
may be employed including content addressable memory (CAM). The calibration information 20 may include a correction factor to be applied to the control input 16 of the semiconductor oscillator 14 to control the output signal frequency. The calibration information 20 may be a function of a change in temperature from a calibration temperature to an operating temperature, as well as being a function of absolute temperature.

[0099] A temperature sensor 22 may sense the temperature of the semiconductor die. Preferably, the temperature sensor is located on the semiconductor die in the vicinity of the semiconductor oscillator 14. Any type of temperature sensor 22 may be used including thermistors and infrared detectors. The temperature sensor 22 may be configured to measure a change in temperature from a baseline temperature or the present temperature.

[0100] FIG. 2 shows a storage technique 30 for storing the calibration information 20 in the non-volatile memory 18. The storage technique 30 may be any form of database including CAM, indexing schemes, look-up tables, and hash tables.

[0101] FIG. 3 shows a series of exemplary graphs 32 of correction factor values versus temperature for maintaining a constant output signal frequency for the crystal oscillator emulator 10. The data for constructing the curve may be attained in any manner including device-level testing and batch-mode testing.

[0102] Exemplary device-level testing may include testing each device to determine correction factors to be applied to the semiconductor oscillator to maintain a constant output frequency with changes in temperature. In one scheme, a baseline value for the semiconductor oscillator control input is determined for a predetermined frequency and at a predetermined temperature of the semiconductor die of the device such as the lowest operating temperature. The baseline value may be measured directly or interpolated from measurement of another device characteristic. Baseline values may also be measured for each potential output frequency. Also, baseline values for each potential output frequency may be extrapolated from the baseline value for the predetermined frequency such as by using a known circuit relationship. The baseline values for each potential output frequency may be stored as absolute values or as a ratio, a frequency factor, to compute the baseline values from a single baseline value.

[0103] The temperature of the semiconductor die is then increased from the lowest operating temperature to the maximum operating temperature in discrete steps. The number of discrete steps is preferably limited to about six temperature levels to reduce testing costs, but any number of discrete steps may be used. Preferably, an on-chip heater is used to heat the semiconductor die, but any means of varying the temperature of the semiconductor die may be employed. At each discrete step, the semiconductor die temperature and the correction factor for maintaining the output at a constant frequency may be measured.

[0104] The correction factor is preferably a ratio to be applied to the baseline value to obtain an adjusted value for the control input. The calibration factor may range from any baseline value such as 1. Preferably, a single correction factor is computed for each temperature step, to be applied to the semiconductor oscillator to maintain the output signal at any one of a multitude of predetermined frequencies. For example, if a correction factor of 1.218 is determined to correspond to a change in temperature of 45 C, then the control input of the semiconductor oscillator may be adjusted as a function of the correction factor such as by changing the control input in proportion to the correction factor. In another alternative, the correction factor may be applied to the baseline value corresponding to the desired output frequency to generate a calibrated value to which the control input is adjusted. In another alternative, correction factors may be measured corresponding to each of several output frequencies at each temperature step.

[0105] Batch-mode testing of crystal oscillator emulators 10 to obtain calibration information 20 may advantageously decrease costs by reducing the number of measurements for a batch of semiconductor dies. In batch-mode testing, the testing results for a subset of crystal oscillator emulators 10 from the same batch of semiconductor dies may be used for all of the devices in the batch. The subset of crystal oscillator emulators that are tested may range from one to any proportion of the total quantity of devices. For example, a single crystal oscillator emulator 10 may be tested and the resulting batch calibration information stored in each of the devices in the batch. In addition, each of the crystal oscillator emulators 10 may be tested for a subset of calibration information such as the output frequency at a baseline temperature. The subset of device specific calibration information may be used to modify the batch calibration information stored in each device.

[0106] FIG. 4 shows another aspect of a crystal oscillator emulator 40. The crystal oscillator emulator 40 is similar to crystal oscillator 10 in function with similar corresponding elements numbered in the range of 40-52, except that crystal oscillator emulator 40 may also include one or more of a heater 54, a controller 56, and a select input 58 alone or in combination.

[0107] The heater 54 may be located on the semiconductor die in the vicinity of the semiconductor oscillator 44 to provide a source of local heating. Any type of heater 54 may be used including transistor heaters and resistive heaters. The heater 54 may be operated in response to an input from the temperature sensor 52 to control the temperature of the semiconductor die. The heater 54 may increase the semiconductor die temperature to a level that corresponds to one of the temperature levels for which correction factors have been determined. In addition, a package having a high thermal impedance may enclose the crystal oscillator emulator 40.

[0108] In one case, the heater 54 may increase the semiconductor die temperature to the maximum operating temperature. Here, during device or batch level testing only the correction factor corresponding to the maximum operating temperature would have to be determined, leading to reduced costs.

[0109] The heater 54 may also be controlled to raise the semiconductor die temperature to the nearest of the prede-
terminated temperature levels while continuously changing the control input during the temperature transition using extrapolated values computed from the correction factors.

[0110] The controller 56 may add extra functionality by for example controlling the heater 54 in response to multiple temperature sensors or manipulating the calibration information 50 to derive values for the control input that correspond to intermediate temperatures. The controller 56 may be any type of entity including a processor, logic circuitry, and a software module.

[0111] The select input 58 may be used for selecting specific output frequencies from within a range of output frequencies. The output frequency may be selected as a function of the impedance of an external component connected to the select input. The external component may be used directly as a portion of the semiconductor oscillator to select the output frequency, or indirectly such as selecting values of impedance within a predetermined range may correspond to predetermined output frequencies. The external component may be any component, but is preferably a passive component such as a resistor or capacitor.

[0112] FIG. 5 shows an aspect of a crystal oscillator emulator 100 having, for example, two select pins 102 and 104 to connect to two external impedances 106 and 108. One or more pins may be used to interface to the external component(s). The crystal oscillator emulator 100 probes or derives information from the external components connected to the select pins 102 and 104. The derived information may have three or more predetermined level ranges that correspond to selected levels of the emulator characteristics. For example, a single pin connected to an external resistor may be used to select any one of 16 output frequency levels. The resistance of the external resistor is preferably selected to be one of 16 predetermined standard values. Each of the 16 values of resistance corresponds to one of the 16 output frequency levels. In addition, low precision passive components are preferably used as the external components to reduce cost and inventory. Each external component may have multiple, N, predetermined nominal values that each correspond to the selection of a predetermined characteristic level. If one pin is used, then N different characteristic levels may be selected. If two pins are used, then N² different characteristic levels may be selected, and so forth for an increasing number of selection pins. The types of device characteristics that for example may be selected include output frequency, frequency tolerance, and baseline correction factor. For example, the crystal oscillator emulator 100 may have a single select pin 102 connected to an external resistor that may have a nominal value selected from a group of 16 predetermined values. Each of the 16 predetermined values has a measured value range which corresponds to one of 16 predetermined output frequency levels possibly ranging from 1 MHz to 100 MHz.

[0113] The external impedances 106 and 108 are preferably resistors, capacitors, or combinations of resistors and capacitors, but may be any component that exhibits predominantly an inductance, resistance, capacitance, or combination thereof. The external impedances 106 and 108 may be connected directly or indirectly from any energy source such as Vdd and ground or any suitable reference to the pins 102 and 104. For example, the external impedance 106 may be connected through a resistor/transistor network to Vdd and through a capacitor network to the select pin 102.

[0114] The crystal oscillator emulator 100 may determine a predetermined select value corresponding to the measured value of the impedance connected to a select pin. Preferably, the impedance is selected to have a standard value such as nominal resistance values corresponding to resistors having a 10% tolerance (e.g., 470, 560, 680, . . .) to reduce device and inventory costs. To account for measurement tolerances and the tolerance of the external impedance, a range of impedance values may correspond to a single select value. The select value is preferably a digital value, but may also be an analog value. For example, values of measured resistance from 2400 ohms to 3000 ohms may be associated with a digital value corresponding to 2. While values of measured resistance from 3001 ohms to 4700 ohms are associated with a digital value corresponding to 3. The measured resistance includes variations due to tolerances of the external impedance and the internal measurement circuit. The impedance measured at each select pin is used to determine a corresponding digital value. The range of digital values may include 3 or more digital values and preferably range from 10 to 16 digital values per select pin. The digital values corresponding to each select pin may be used in combination to describe memory addresses. For example, a device having three select pins each to interface to impedances that are mapped into one of 10 digital values, may describe 1000 memory addresses or lookup table values. The contents of the storage locations corresponding to the memory addresses are used to set a value for an output or internal characteristic of the device. Another exemplary device may include two select pins, each configured to interface to external impedances that are mapped to a digital value within a range of 10 values. The digital values in combination may describe 100 memory addresses or lookup table values that may each contain data for setting a characteristic of the crystal oscillator emulator 100.

[0115] FIG. 6 shows a block diagram of an aspect of a crystal oscillator emulator 120. The crystal oscillator emulator 120 includes a select pin 122 to interface to an external impedance 124 that is used for selecting a configuration of the crystal oscillator emulator 120. The external impedance 124 is similar in function and scope to the external impedances 116 and 118.

[0116] A measurement circuit 126 connected to the select pin 122 measures an electrical characteristic that is a function of the external impedance 124. For example, a current may be supplied to the external impedance and the voltage that is developed across the external impedance 124 then measured. Also, a voltage may be impressed across the external impedance 124 and then measure the current. Any measurement technique for measuring passive components may be used to measure the electrical characteristic including dynamic as well as static techniques. Exemplary measurement techniques include timing circuits, analog to digital converters (ADCs), and digital to analog converters (DACs). Preferably, the measurement circuit has a high dynamic range. The measurement circuit 126 may generate an output having a value corresponding to the value of the external impedance 124. The output may be either digital or analog. The same output value preferably represents a range of external impedance values to compensate for value variations such as tolerances in the external impedance values, interconnect losses, and measurement circuit tolerances due to factors including process, temperature, and power. For example, all measured external impedance values ranging
from greater than 22 up to 32 ohms may correlate to a digital output value of “0100”. While measured external impedance values ranging from greater than 22 up to 54 ohms may correlate to a digital output value of “0101”. The actual external impedance values are a subset of the measured external impedance value to account for the value variations. For example, in the above cases the actual external impedance values might be from 24 to 30 ohms and from 36 to 50 ohms. In each case an inexpensive low precision resistor may be selected to have a value centered within the range, such as 27 ohms and 43 ohms. In this way, inexpensive low precision components may be used to select amongst a range of high precision outputs. The select value may be used directly as a variable value to control a device characteristic of the crystal oscillator emulator 120. The variable value may also be determined indirectly from the select value.

[0117] A storage circuit 127 may include variable values that may be selected as a function of the select value. The storage circuit 127 may be any type of storage structure including content addressable memory, static and dynamic memory, and look-up tables.

[0118] For the case that the measurement circuit 126 generates output values that have a one-to-one correspondence to the external impedance values, a digital value determiner 128 may then set the output value to a select value that corresponds to a range of external impedance values.

[0119] FIG. 7A shows a relationship between groups of impedance values 150 and associated select values 154. The groups of impedance values 150 have a one-to-one correspondence to groups of digital output values 152 which are converted to the select values 154 associated with each of the groups of impedance values 150. The impedance values ranging from a minimum impedance value to a maximum impedance are separated into three or more groups, with each group having a nominal impedance. The nominal impedance values of each of the groups may be selected to have a spacing between nominal impedance values. Here, the nominal values, 27 ohms and 43 ohms, of the groups of impedance values have a spacing of 16 ohms. This direct correspondence between the ranges of impedance values 156 and associated select values 158 may be implemented by, for example, a nonlinear analog to digital converter (not shown).

[0121] Referring back to FIG. 6, an address generator 130 may determine memory locations corresponding to the digital output values associated with external impedances connected to the select pins. The memory locations may be grouped in any manner such as a list for a single select pin, a lookup table for two select pins, and a third order table for three select pins.

[0122] A controller 132 may set a device characteristic of the crystal oscillator emulator 120 as a function of the variable value. The variable value may be generated directly by the measurement circuit, determined indirectly from the select value, and determined from the contents of a memory location corresponding to the external impedance values connected to the select pins.

[0123] The select pin 124 may also be used for implementing an additional function such as power down (PD), power enable, mode selection, reset, and synchronous operation. In this aspect, the select pin 124 becomes a multi-purpose select pin 128 for configuring the crystal oscillator emulator 120 as well as implementing the additional function.

[0124] In one aspect, a first range of impedance values connected to the multi-purpose select pin 124 may be used to configure the crystal oscillator emulator 120, while operation of the additional function may be controlled by a voltage or current impressed on the multi-purpose select pin 124, or impedance values outside the first range of impedance values.

[0125] FIG. 8 shows an aspect of an oscillator assembly 200 to generate an output having a periodic waveform. The oscillator assembly 200 includes a crystal oscillator emulator 202 to drive a phase lock loop (PLL) 204. The crystal oscillator emulator 202 may be similar in function and structure to the aspects of the crystal oscillator emulators described above. The oscillator assembly 200 may include any type of PLL 204 such as digital PLLs and analog PLLs.

[0126] Multi-purpose select pins 206 and 208 may be used for the selection of the operating parameters for the PLL 204 such as the divider factor. The multi-purpose select pins 206 and 208 may also be used for control and operation of the crystal oscillator emulator 202 such as output frequency selection and reception of a reference clock for calibration. External resistors 210 and 212 may be connected to the multi-purpose select pins 206 and 208 to select the operating frequency. The ranges of values of the external resistors 210 and 212 correspond to the selection of different operating frequencies. Each external resistor 210 and 212 may be used to select one of 16 predetermined operating frequencies. In combination, the external resistors 210 and 212 may select from amongst 256 operating frequencies. To control multiple functions, each of the multi-purpose select pins 206 and 208 may receive signals within different voltage ranges. For example, one multi-purpose select pin 206 may connect to an external resistor 210 across which a voltage in the range
of 0 to 2 volts may be developed to determine the resistance, and the multi-purpose select pin 206 may also receive a reference clock signal operating in a range of 2 to 3 volts. A decoder 214 may detect signals on the multi-purpose select pins 206 and 208.

[0127] FIG. 9 shows a spread spectrum oscillator 300 for generating an output signal having a variable frequency. The spread spectrum oscillator 300 includes a crystal oscillator emulator 302 connected to a PLL 304. A frequency control device connected to the crystal oscillator emulator 302 may dynamically control the output frequency of the crystal oscillator emulator 302. The frequency control device may be any device or technique including a variable, controlling the bias current source of the semiconductor oscillator, and controlling the control input voltage applied to the resonant capacitors of the semiconductor oscillator.

[0128] FIG. 10 shows the operation of an aspect of a crystal oscillator emulator. At block 400, a semiconductor oscillator is provided for generating an output signal having a periodic waveform. Continuing to block 402, the semiconductor oscillator may be calibrated to generate a constant frequency over a predetermined range of temperature. In one aspect, the calibration may include varying the temperature of the semiconductor die over a predetermined temperature range and measuring calibration information for maintaining a constant output frequency. The die temperature may be measured in the vicinity of the semiconductor oscillator. The calibration information may include control input values versus die temperatures for maintaining a constant output frequency. The calibration information may be stored in non-volatile memory on the semiconductor die. At block 404, an operating frequency may be determined by probing an external component. Continuing to block 406, the semiconductor oscillator generates an output signal having an operating frequency. At block 408, the temperature of the semiconductor die is determined in the vicinity of the semiconductor oscillator. Continuing to block 410, the semiconductor die may be heated or cooled to control the die temperature to one or more predetermined temperature levels. At block 412, the control input may be controlled as a function of the die temperature to compensate for changes in the operating frequency of the output signal caused by temperature changes. The stored calibration information may be used to control the control input. The calibration information may be used directly for die temperatures that correspond to stored temperatures. For other die temperatures, the control input value may be extrapolated from the stored calibration information. Continuing to block 414, the frequency of the output signal may be dynamically varied as a function of a frequency control signal.

[0129] FIG. 11 shows an aspect of a low power oscillator 320 for generating a periodic signal. The low power oscillator 320 includes a crystal oscillator emulator 322 to calibrate an active silicon oscillator 324. The crystal oscillator emulator 322 is normally in the off state to reduce power consumption. At predetermined intervals, the crystal oscillator emulator 322 is switched to the powered on state to calibrate the active silicon oscillator 324. The active silicon oscillator 324 consumes less power than the crystal oscillator emulator 322, so operating the active silicon oscillator 324 continuously while only operating the crystal oscillator emulator 322 intermittently reduces the overall power consumption of the low power oscillator 320. Any type of active silicon oscillator may be used including ring oscillators and RC oscillators. The crystal oscillator emulator 324 may be configured in accordance with any of the aspects of the invention as described and shown in this specification.

[0130] A summer 326 may determine the frequency error between the active silicon oscillator output and the crystal oscillator emulator output. A controller 328 may generate a control signal, based on the frequency error, to control the frequency of the active silicon oscillator 324. The controller 328 may also receive temperature information from the crystal oscillator emulator 322. The temperature information may include temperatures such as the temperature of the semiconductor and the ambient temperature. The controller 328 may include calibration information for the active silicon oscillator 324 similar to the calibration information for the crystal oscillator emulator 322. The frequency error may be used to set an initial value for the control signal and then the temperature information in combination with the active silicon oscillator calibration information may be used to update the control signal while the crystal oscillator emulator 322 is powered down. In one aspect, the temperature sensing circuit of the crystal oscillator emulator 322 may remain continuously powered so that continuous temperature information may be supplied to the controller 328. The control signal 334 may be either digital or analog. If the control signal is digital, a digital-to-analog converter (DAC) 330 may convert the control signal to analog.

[0131] A regulator 332 may, in response to the control signal 334, control the supply of power for the active silicon oscillator 324 to adjust the operating frequency. The supply of voltage and/or current to the active silicon oscillator 324 may be controlled. For example, the regulator 332 may control the voltage level of the supply voltage.

[0132] In operation, the active silicon oscillator 324 is normally in the on state generating a periodic output signal. The crystal oscillator emulator 322 is normally in the off state. In the off state, either all or a portion of the crystal oscillator emulator 322 may be powered off to conserve power. At a predetermined time, power is applied to the crystal oscillator emulator 322. The semiconductor oscillator of the crystal oscillator emulator 322 is then calibrated with the stored calibration information. The frequency of the output signal of the crystal oscillator emulator 322 is compared with the frequency of the output signal of the active silicon oscillator 324 to determine the frequency error of the active silicon oscillator 324. The control signal 334 changes in response to the frequency error, causing a shift in the supply voltage from the voltage regulator 332, leading to a change in the output frequency of the active silicon oscillator 324, reducing the frequency error.

[0133] FIG. 12 shows an aspect of another low power oscillator 350 for generating a periodic signal. The low power oscillator 350 includes a crystal oscillator emulator 352 in communication with a charge pump oscillator 354. The crystal oscillator emulator 352 is normally in the powered down state to reduce power consumption. During the powered down state, either all or a portion of the crystal oscillator emulator 352 may be powered down. At predetermined intervals, the crystal oscillator emulator 352 may be powered up and used to calibrate the charge pump oscillator 354. The predetermined intervals may be deter-
minded as a function of any circuit parameter such as operating time, temperature change of the semiconductor, ambient temperature change, temperature of the semiconductor, and supply voltage change.

[0134] The charge pump oscillator 354 may include a charge pump 356, loop filter 358, voltage controlled oscillator (VCO) 360, and phase detector 362. The charge pump oscillator 354 is similar in operation to conventional charge pump oscillators, except that the reference input of the phase detector 362 receives a reference clock signal from the crystal oscillator emulator 352.

[0135] A multiplexer 364 receives the output signals from the crystal oscillator emulator 352 and the charge pump oscillator 354. One of the output signals is selected and passed through the multiplexer 375 to a phase locked loop 366. The phase locked loop 366 generates an output signal as a function of the output signals from the crystal oscillator emulator 352 and the charge pump oscillator 354.

[0136] In operation, the charge pump oscillator 354 is normally in the on state generating a periodic output signal. The crystal oscillator emulator 352 is normally in the off state. In the off state, either all or a portion of the crystal oscillator emulator 352 may be powered off to reduce power consumption. At a predetermined time, power is applied to the crystal oscillator emulator 352. The semiconductor oscillator of the crystal oscillator emulator 352 is then calibrated with the stored calibration information. The output signal of the crystal oscillator emulator 352 is compared with the output signal of the charge pump oscillator 354 to determine the phase error of the charge pump oscillator 324. The VCO 360 is then controlled to reduce the phase error so that the output signal of the charge pump oscillator 354 is calibrated to the output signal of the crystal oscillator emulator 352. One of the output signals may then be selected and applied to the PLL 366.

[0137] Referring now to FIGS. 13-15, an integrated circuit 500 includes a crystal oscillator emulator 502 that generates a clock signal. One or more circuits 504 in the integrated circuit 500 receive the clock signals. The crystal oscillator emulator 502 can be implemented as described above in conjunction with FIGS. 1-12. The circuits 502 can include a processor 512 as shown in FIG. 14 or other circuits. An external component 506 can optionally be used to select the clock frequency of the crystal oscillator emulator 502 as shown in FIGS. 13 and 15.

[0138] Referring now to FIGS. 16-18, an integrated circuit 518 includes a clock divider 520 that generates clock signals at other one or more other clock frequencies for circuits 522-1, 522-2, . . . , and 522-N (collectively circuits 522). The circuits 522 may be interconnected to each other in any manner. The clock divider 520 divides the clock by an integer such as X or Y without the clock signal by Y for 1/X, Y and/or Y/X adjustments. The clock divider 520 may also use one or more other additional ratios and/or divisors for producing different clock signals for other circuits 522. The clock divider 520 outputs N-1 clock signals as shown to N-1 circuits 522 in the integrated circuit 518.

[0139] In FIG. 17, one of the circuits includes a processor 530. The processor 530 can be connected to the clock divider 520 instead of and/or in addition to the crystal oscillator emulator 502. Additional circuits 532-1, 532-1, and 532-N communicate with the clock divider 520.

[0140] In FIG. 18, the crystal oscillator emulator 502 provides clock signals for a processor 530, a graphics processor 540, memory 542 and/or one or more circuits 544 in the integrated circuit 518. A clock divider (not shown) may also be provided. The processor 530, graphics processor 540, memory 542 and/or other circuits 544 may be interconnected in any suitable manner.

[0141] Referring now to FIG. 19, an integrated circuit 600 includes one or more circuits 602-1, 602-2, . . . , and 602-N (collectively circuits 602) and the low power oscillator 320, which operates as described above in conjunction with FIG. 11. One of the circuits may include a processor as shown at 610. A clock divider (not shown) may also be provided as described above.

[0142] Integrated circuits (IC) are typically encased in a packaging material. The packaging material may include plastic. The IC substrate may include pads that are connected to leads by bondwires. The IC substrate, the bondwires and portions of the leads may be encased in the plastic. The properties of the packaging material that is normally used in packaging the IC may change over time. The changes may cause an oscillation frequency of an on-chip oscillator to drift over time. The changes in the packaging may be due to changes in the dielectric loss of the packaging material over time. The changes in the packaging may also be due to water absorption of the packaging material at different humidity levels. As a result, the packaging material may limit the achievable calibrated accuracy.

[0143] Referring now to FIG. 20, an integrated circuit 700 is encapsulated in a packaging material 704 according to the prior art. As can be appreciated, characteristics of the packaging material 704 may change over time and/or as a function of environmental conditions. For example, when the packaging material 704 includes plastic material, the dielectric loss of the plastic material may change over time, which may have an adverse impact upon calibration accuracy. As used herein, the term dielectric loss refers to loss of energy that eventually produces a rise in temperature of a dielectric placed in an alternating electrical field. Heating is due to “molecular friction” of dipoles within the material as the dipoles try to reorient themselves with the oscillating (electrical) field of the incident wave. For example, when heating food in a microwave, the dipoles associated with water in the food vibrate and are heated. Some materials such as certain plastics are not suitable for use in microwaves since they absorb too much heat. These materials have high dielectric loss characteristics. Other materials such as other types of plastics experience little or no heating. These materials have lower dielectric loss characteristics. Since the circuits described herein may operate at microwave frequencies, low dielectric loss materials are preferred.

[0144] Water absorption of the plastic material over time may also adversely impact calibration accuracy. Since water has a high dielectric loss, increased water content in the packaging material tends to increase the dielectric loss of the packaging material. In other features, the packaging material may also be a low stress material. High stress materials tend to warp, which may affect circuit characteristics of adjacent circuits such as by changing channel lengths. As used herein, the term low stress refers to packaging materials that tend to be stable and not change the electrical characteristics of the
integrated circuit due to changes in stress. In some implementations, the packaging material has a dielectric loss factor (DLF) that is less than or equal to Teflon at the relevant frequency of operation, such as greater than 1 GHz.

[0145] Referring now to FIG. 21, an integrated circuit 710 with an on-chip semiconductor oscillator 711 with temperature compensation is shown encapsulated in a packaging material 714 having a low dielectric loss according to the present invention. The packaging material 714 may be a plastic packaging material having low dielectric loss. As used herein, the term “low dielectric loss” refers to materials having a dielectric loss that is less than or equal to Teflon at a relevant operating frequency of the IC. The operating frequency of the IC may be above 1 GHz and/or 2.4 GHz. The packaging material 714 may also comprise Teflon®, Teflon® PolyChloroTrifluoroethylene (PCTFE), Teflon® Teflon® fluorinated ethylene propylene copolymer (FEP), perfluoroalkoxy (PFA), Tefzel® and Teflon® copolymer of ethylene and tetrafluoroethylene (ETFE), low dielectric loss plastic, high quality glass, air and/or other materials. Any other packaging materials having dielectric loss that is less than or equal to Teflon are contemplated. The packaging material also may have relatively low water absorption.

[0146] Referring now to FIG. 22, an exemplary implementation of the integrated circuit package of FIG. 21 is shown in further detail. An integrated circuit package 718 includes an integrated circuit 724 that includes pads 728. Leads 732 of a lead frame 733 are connected by bondwires 734 to the pads 728 of the integrated circuit. As can be appreciated, the integrated circuit includes an on-chip semiconductor oscillator with temperature compensation as described above. Portions of the leads 732, the bondwires 734 and the integrated circuit 724 are encapsulated in a packaging material 736. The packaging material 736 may be a plastic packaging material having low dielectric loss. As can be appreciated, other types of packaging such as ball grid array (BGA), flip chip and/or any other suitable packaging technique may be employed in this embodiment and/or others that precede or follow.

[0147] Referring now to FIG. 23, an alternate integrated circuit package 738 includes an on-chip, temperature-compensated semiconductor oscillator 741 according to the present invention. In this embodiment, the semiconductor oscillator 741 comprises an integrated circuit inductor 742. A glass layer 744 is bonded to the integrated circuit substrate 740 using a very thin epoxy layer 750. The epoxy layer 750 may have a low dielectric loss. The glass layer 744, the epoxy layer 750 and the integrated circuit substrate 740 are encapsulated in a packaging material 760. In this case, the dielectric loss of the packaging material is less critical due to the distance between the inductor 742 and the packaging material 760. Therefore, changes in the dielectric loss and/or other characteristics of the packaging material 760 are less critical as a function of time. However, the packaging material can be low dielectric loss material. While the glass layer is shown over the entire integrated circuit, the glass layer may be limited to a smaller region immediately adjacent to the semiconductor oscillator.

[0148] Referring now to FIGS. 24 and 25, an alternate integrated circuit package including an on-chip semiconductor oscillator according to the present invention is shown. This embodiment is similar to that shown and described above in conjunction with FIG. 23. However, the glass layer 744 defines a cavity 746. The cavity 746 is adjacent to, aligned with and extends over the inductor 742. An air cavity 752 is formed between the inductor 742 and the glass layer 744. A thin epoxy layer 750 is formed between the glass layer 744 and the integrated circuit substrate 740 in areas other than the cavity 746. The glass layer 744 may be etched to define the cavity and dipped in epoxy. Adjacent, the glass layer may include multiple layers of glass and at least one layer has a cavity formed therein.

[0149] Referring now to FIG. 26, a capacitor of an on-chip semiconductor oscillator may be adjusted based upon temperature compensation as previously described above. As can be appreciated, there are other ways of adjusting the oscillating frequency independent from adjusting the capacitor and/or inductor of the semiconductor oscillator.

[0150] Referring now to FIG. 27, an integrated circuit 830 includes a fractional phase locked loop 831 with a temperature compensation input. The fractional phase locked loop 831 includes a phase frequency detector 836 that receives an output of the integrated circuit oscillator 832, which operates as described above. The phase frequency detector 836 generates a differential signal based on a difference between a reference frequency and a VCO frequency. The differential signal is output to a charge pump 840. An output of the charge pump 840 is input to an optional loop filter 844. An output of the loop filter 844 is input to a voltage controlled oscillator (VCO), which generates a VCO output having a frequency that is related to a voltage input thereto. An output of the VCO 846 is fed back to a scaling circuit 850. The scaling circuit 850 selectively divides the VCO frequency by N or N+1. While N and N+1 divisors are employed, the divisors may have other values.

[0151] An output of the scaling circuit 850 is fed back to the phase frequency detector 836. A temperature sensor 850 measures a temperature of the integrated circuit 830 in the region near the IC oscillator 832. The temperature sensor 850 outputs a temperature signal that is used to address calibration information 858 that is stored in memory 856. The selected calibration information is used to adjust the scaling circuit 850. The selected calibration information adjusts a ratio of the divisors N and N+1 that are used by the scaling circuit 844.

[0152] Referring now to FIG. 28, a Delta-Sigma fractional phase locked loop 858 is shown for an integrated circuit 860 that includes a temperature compensation input. The selected calibration information is used to adjust an output of a Sigma Delta modulator 870. The selected calibration information may adjust a modulation between the divisors N and N+1 that are used by the scaling circuit 844.

[0153] Referring now to FIG. 29, a flow chart 900 illustrates steps for measuring sampling calibration points using a linear curve fitting algorithm to generate the calibration data. Control begins with step 902. In step 904, control measures sample calibration points at a plurality of temperatures. In step 906, linear curve fitting algorithms are used to generate curves for other temperature points between the sample points. In step 908, control ends.

[0154] Referring now to FIG. 30, a flow chart 920 illustrating steps for measuring sampling calibration points and
Referring now to FIGS. 31A-31G, various exemplary implementations of the present invention are shown. Referring now to FIG. 31A, the present invention can be implemented in a hard disk drive 1000. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31A at 1002. In some implementations, the signal processing and/or control circuit 1002 and/or other circuits (not shown) in the HDD 1000 may process data, perform coding and/or encryption, perform calculations, and/or format data that is output to and/or received from a magnetic storage medium 1006.

The HDD 1000 may communicate with a host device (not shown) such as a computer, mobile computing devices such as personal digital assistants, cellular phones, media or MP3 players and the like, and/or other devices via a one or more wired or wireless communication links 1008. The HDD 1000 may be connected to memory 1009 such as random access memory (RAM), low latency nonvolatile memory such as flash memory, read only memory (ROM) and/or other suitable electronic data storage.

Referring now to FIG. 31B, the present invention can be implemented in a digital versatile disc (DVD) drive 1010. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31B at 1012, and/or mass data storage of the DVD drive 1010. The signal processing and/or control circuit 1012 and/or other circuits (not shown) in the DVD 1010 may process data, perform coding and/or encryption, perform calculations, and/or format data that is read from and/or data written to an optical storage medium 1016. In some implementations, the signal processing and/or control circuit 1012 and/or other circuits (not shown) in the DVD 1010 can also perform other functions such as encoding and/or decoding and/or any other signal processing functions associated with a DVD drive.

The DVD drive 1010 may communicate with an output device (not shown) such as a computer, television or other device via a one or more wired or wireless communication links 1017. The DVD 1010 may communicate with mass data storage 1018 that stores data in a nonvolatile manner. The mass data storage 1018 may include a hard disk drive (HDD). The HDD may have the configuration shown in FIG. 31A. The HDD may be a mini HDD that includes one or more platters having a diameter that is smaller than approximately 1.8". The HDD 1018 may be connected to memory 1019 such as RAM, ROM, low latency nonvolatile memory such as flash memory and/or other suitable electronic data storage.

Referring now to FIG. 31C, the present invention can be implemented in a high definition television (HDTV) 1020. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31E at 1022, a WLAN interface and/or mass data storage of the HDTV 1020. The HDTV 1020 receives HDTV input signals in either a wired or wireless format and generates HDTV output signals for a display 1026. In some implementations, signal processing circuit and/or control circuit 1022 and/or other circuits (not shown) of the HDTV 1020 may process data, perform coding and/or encryption, perform calculations, format data and/or perform any other type of HDTV processing that may be required.

The present invention may also be implemented in other control systems 1040 of the vehicle 1030. The control system 1040 may also communicate with any other control systems 1040. The control system 1040 may also support connections with a WLAN via a WLAN network interface 1048. The control system 1040 may also include mass data storage, memory and/or a WLAN interface (not all shown).

Referring now to FIG. 31E, the present invention can be implemented in a cellular phone 1050 that may
include a cellular antenna 1051. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31E at 1052, a WLAN interface and/or mass data storage of the cellular phone 1050. In some implementations, the cellular phone 1050 includes a microphone 1056, an audio output 1058 such as a speaker and/or audio output jack, a display 1060 and/or an input device 1062 such as a keypad, pointing device, voice actuation and/or other input device. The signal processing and/or control circuits 1052 and/or other circuits (not shown) in the cellular phone 1050 may process data, perform coding and/or encryption, perform calculations, format data and/or perform other cellular phone functions.

[0165] The cellular phone 1050 may communicate with mass data storage 1064 that stores data in a nonvolatile manner such as optical and/or magnetic storage devices for example hard disk drives HDD and/or DVDs. At least one HDD may have the configuration shown in FIG. 31A and/or at least one DVD may have the configuration shown in FIG. 31B. The HDD may be a mini HDD that includes one or more platters having a diameter that is smaller than approximately 1.8\". The cellular phone 1050 may be connected to memory 1066 such as RAM, ROM, low latency nonvolatile memory such as flash memory and/or other suitable electronic data storage. The cellular phone 1050 also may support connections with a WLAN via a WLAN network interface 1068.

[0166] Referring now to FIG. 31F, the present invention can be implemented in a set top box 1080. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31F at 1084, a WLAN interface and/or mass data storage of the set top box 1080. The set top box 1080 receives signals from a source such as a broadband source and outputs standard and/or high definition audio/video signals suitable for a display 1088 such as a television and/or monitor and/or other video and/or audio output devices. The signal processing and/or control circuits 1084 and/or other circuits (not shown) of the set top box 1080 may process data, perform coding and/or encryption, perform calculations, format data and/or perform any other set top box function.

[0167] The set top box 1080 may communicate with mass data storage 1090 that stores data in a nonvolatile manner. The mass data storage 1090 may include optical and/or magnetic storage devices for example hard disk drives HDD and/or DVDs. At least one HDD may have the configuration shown in FIG. 31A and/or at least one DVD may have the configuration shown in FIG. 31B. The HDD may be a mini HDD that includes one or more platters having a diameter that is smaller than approximately 1.8\". The set top box 1080 may be connected to memory 1094 such as RAM, ROM, low latency nonvolatile memory such as flash memory and/or other suitable electronic data storage. The set top box 1080 also may support connections with a WLAN via a WLAN network interface 1096.

[0168] Referring now to FIG. 31G, the present invention can be implemented in a media player 1100. The present invention may implement any integrated circuit such as either or both signal processing and/or control circuits, which are generally identified in FIG. 31G at 1104, a WLAN interface and/or mass data storage of the media player 1100. In some implementations, the media player 1100 includes a display 1107 and/or a user input 1108 such as a keypad, touchscreen and the like. In some implementations, the media player 1100 may employ a graphical user interface (GUI) that typically employs menus, drop down menus, icons and/or a point-and-click interface via the display 1107 and/or user input 1108. The media player 1100 further includes an audio output 1109 such as a speaker and/or audio output jack. The signal processing and/or control circuits 1104 and/or other circuits (not shown) of the media player 1100 may process data, perform coding and/or encryption, perform calculations, format data and/or perform any other media player function.

[0169] The media player 1100 may communicate with mass data storage 1110 that stores data such as compressed audio and/or video content in a nonvolatile manner. In some implementations, the compressed audio files include files that are compliant with MP3 format or other suitable compressed audio and/or video formats. The mass data storage may include optical and/or magnetic storage devices for example hard disk drives HDD and/or DVDs. At least one HDD may have the configuration shown in FIG. 31A and/or at least one DVD may have the configuration shown in FIG. 31B. The HDD may be a mini HDD that includes one or more platters having a diameter that is smaller than approximately 1.8\". The media player 1100 may be connected to memory 1114 such as RAM, ROM, low latency nonvolatile memory such as flash memory and/or other suitable electronic data storage. The media player 1100 also may support connections with a WLAN via a WLAN network interface 1116. Still other implementations in addition to those described above are contemplated.

[0170] Referring now to FIGS. 32A-32D, an integrated circuit package is shown that incorporates an annealed glass paste or epoxy as a layer and/or “islands” adjacent to one or more selected features of a silicon wafer. One or more “islands” of the annealed glass paste or epoxy layer can be made on portions of one or both sides of the silicon wafer. In FIG. 32A, an alternate integrated circuit package 1200 includes a silicon wafer 1204. An annealed glass paste layer or portions 1206 is/are formed on the silicon wafer 1204. A molding material 1208 may be used to encapsulate all or part of the silicon wafer 1204. The annealed glass paste layer 1206 also reduces the change in stress over time. The annealed glass paste layer 1206 tends to isolate all or part of the silicon wafer 1204 from variations in the dielectric properties such as dielectric loss of the molding material 1208.

[0171] The silicon wafer 1204 may include a semiconductor oscillator as described above. The annealed glass paste layer 1206 may include a glass paste having a relatively low annealing temperature. The low annealing temperature may be lower than a temperature that would damage the silicon wafer 1204. The glass paste layer 1206 may include glass frit paste. The glass paste layer may be applied in any suitable manner. The glass paste layer may be applied using a screen printing approach, a dipping approach, a masking approach, and/or using any other suitable approach.

[0172] In FIG. 32B, an alternate integrated circuit package 1210 includes a conductive material layer or coating 1212 that is applied to the glass paste or epoxy layer 1204.
The conductive material layer 1212 may include a layer of conductive epoxy. The conductive material layer 1212 may be applied as a liquid and cured. The conductive material layer 1212 may include conductive epoxy paint. The conductive material layer 1212 may be applied in any suitable fashion including dipping the silicon wafer 1204 into a container such as a dish that contains the conductive material. The conductive material layer 1212 tends to reduce electro-magnetic interference from external devices.

[0173] In FIG. 32C, an integrated circuit package 1220 includes the annealed glass paste layer 1206, which is applied to selected portions of the silicon wafer 1204. In FIG. 32D, an integrated circuit package 1230 includes the annealed glass paste or epoxy portions 1206 and the conductive material 1212. The conductive material 1212 may cover the annealed glass paste layer 1206 while touching or not touching the silicon wafer 1204.

[0174] Referring now to FIGS. 33A-33D, alternate integrated circuit packages are shown. In FIG. 33A, an alternate integrated circuit package 1240 includes the annealed glass paste layer 1206 and the conductive material layer 1212, which are located adjacent to circuit components 1242 of the silicon wafer 1204. In FIG. 33B, an alternate integrated circuit package 1250 includes the annealed glass paste layer 1206 and conductive material layer 1212, which are located adjacent to an oscillator 1252 of the silicon wafer 1204.

[0175] In FIG. 33C, an alternate integrated circuit package 1260 includes the annealed glass paste layer 1206 and conductive material layer 1212, which are located adjacent to an inductor 1262 of the silicon wafer 1204. The inductor 1262 may be an on-chip inductor such as a spiral inductor. In FIG. 33D, an alternate integrated circuit package 1270 includes the annealed glass paste layer 1206 and conductive material layer 1212, which are located adjacent to oscillator circuit 1272 with an inductor 1274.

[0176] The annealed glass paste layer also tends to reduce the change in stress over time that can occur. The annealed glass paste layer isolates all or part of the silicon wafer from variations in the dielectric properties such as dielectric loss of the molding material. This can be particularly advantageous when attempting to calibrate using temperature as described above.

[0177] Referring now to FIGS. 34A-34D, alternate integrated circuit packages are shown that include annealed glass paste and/or epoxy portions and a glass or silicon layer that creates an air gap above portions of a silicon wafer. In FIGS. 34A-34B, integrated circuit packages 1300 and 1330 include a silicon wafer 1304. Annealed glass paste portions 1306 are formed on the silicon wafer 1304 in a spaced apart relationship. The AGP portions 1306 may be formed as described above. A molding material 1308 may be used. Post-processing of the AGP portions 1306 may be performed such as polishing or other steps to provide a planar outer surface.

[0178] A glass or silicon layer 1310 is supported above the silicon wafer 1304 by the AGP portions 1306. Epoxy or other adhesive binding material may be used to attach the glass or silicon layer 1310 to the AGP portions 1306. AGP portions 1306 and the glass or silicon layer 1310 form an air gap 1324 above an oscillator 1320 in FIG. 34A and/or any other circuit 1322 in FIG. 34B. The air gap 1324 provides the material (air) having the lowest possible dielectric loss. In contrast, when crystal oscillators are used, the air is needed to allow the crystal to resonate—in other words, the air is used to allow mechanical oscillation.

[0179] In FIGS. 34C-34D, integrated circuit packages 1340 and 1360 include a silicon wafer 1304. Epoxy portions 1342 are formed on the silicon wafer 1304 in a spaced apart relationship. The epoxy portions 1342 may be formed as described above. Post-processing of the epoxy portions 1306 may be performed such as polishing or other steps to provide a planar outer surface. A glass or silicon layer 1310 is supported above the silicon wafer 1304 by the epoxy portions 1342. Epoxy or other adhesive binding material may be used to attach the glass or silicon layer 1310 to the epoxy portions 1342. The portions 1306 and the layer 1310 form an air gap 1324 above an oscillator 1320 in FIG. 34C and/or any other circuit 1322 in FIG. 34D.

[0180] Referring now to FIGS. 35A-35B, alternate integrated circuit packages are shown that include a glass or silicon portion that creates an air gap. In FIG. 35A, an integrated circuit package the 1380 includes a “C”-shaped glass or silicon portion 1382 that defines an air gap 1384. The “C”-shaped glass or silicon portion 1382 may include multiple sections that are joined together. The air gap 1384 is located above an oscillator 1320. In FIG. 35B, an integrated circuit package 1390 includes a “C”-shaped glass or silicon layer 1382 that defines an air gap 1384. The air gap 1384 is located above a circuit 1322.

[0181] Referring now to FIGS. 36A-36C, methods for making integrated circuit packages described above are shown. An integrated circuit structure 1400 includes a silicon wafer 1404, a plurality of spaced AGP and/or epoxy portions 1410A and 1410B (collectively portions 1410), and a glass or silicon layer 1408. The integrated circuit structure 1400 is cut into sections along dotted cutlines 1414 to create multiple integrated circuits, which can be packaged in a molding material (not shown) as described above.

[0182] In FIG. 36B, the silicon wafer 1404 may include one or more bond pads 1420. Cutting of the layer 1408 at 1414-1 and 1414-2 may be offset from the cutting of the silicon wafer at 1414-3 to provide clearance for attaching bondwires (not shown) to the bond pads 1420. In FIG. 36C, one of the integrated circuits 1450 is shown after being separated from the integrated circuit structure 1400.

[0183] Referring now to FIGS. 37A-37B, an integrated circuit package 1450 includes a silicon wafer with spaced annealed glass paste and/or epoxy portions 1410 that have been coated with a layer of conductive material 1456 are shown. In FIG. 37A, the portions 1410 are dipped into a container 1454 that contains the conductive material 1456. The silicon wafer 1408 may be diced along one or more cutlines 1462 and may include bond pads 1460 as shown.

[0184] Referring now to FIG. 38, steps of a method 1500 for fabricating the integrated circuit packaging of FIGS. 32A-33D are shown. Control begins in step 1502. In step 1504, a glass paste layer 1206 is applied to one or more surfaces of the silicon wafer 1204 and/or select areas of the silicon wafer 1204. In step 1506, the glass paste layer 1204 is annealed by placing the silicon wafer 1204 and the glass paste layer 1204 in an oven. The temperature of the oven may be set to a temperature that is sufficient to cure the glass.
paste layer 1204. For example, a temperature of around 400° C. for a predetermined period is sufficient to anneal the glass frit paste while not damaging the silicon wafer 1204. In step 1508, the conductive material layer 1212 is applied to the annealed glass paste layer 1204. In step 1510, all or part of the silicon wafer 1204 is encased in a molding material 1208 such as plastic, other materials described herein, and/or other suitable molding materials. In step 1520, control ends.

[0185] In each of the foregoing embodiments, the silicon wafer may be replaced by other wafers or other substrates and the annealed glass paste can be replaced by epoxy.

[0186] A number of embodiments of the invention have been described. Nevertheless, it will be understood that various modifications may be made without departing from the spirit and scope of the invention. Accordingly, other embodiments are within the scope of the following claims.

What is claimed is:

1. An integrated circuit comprising:
   a temperature sensor that senses a temperature of said integrated circuit;
   a memory module that stores oscillator data relating to calibrations and that selects one of said oscillator calibrations as a function of said sensed temperature;
   an oscillator module that generates a reference signal having a frequency; and
   a phase locked loop module comprising a feedback loop having a feedback loop parameter, wherein said phase locked loop module selectively adjusts said feedback loop parameter based on said selected one of said oscillator calibrations.

2. The integrated circuit of claim 1 wherein said phase locked loop module comprises a fractional phase locked loop module and said feedback loop parameter is a ratio of a scaling factor.

3. The integrated circuit of claim 2 wherein said fractional phase locked loop module comprises:
   a phase frequency detector module that communicates with said oscillator module and that receives said reference frequency;
   a charge pump module that communicates with said phase frequency detector module;
   a voltage controlled oscillator module that communicates with said charge pump module and that generates an output frequency;
   a scaling module that communicates with said voltage controlled oscillator and said phase frequency detector module and that selectively adjusts said output frequency first and second scaling factors, wherein said scaling module adjusts a ratio of said first and second scaling factors based on said selected one of said oscillator calibrations.

4. The integrated circuit of claim 3, wherein said first and second scaling factors are divisors equal to N and N+1, and wherein N is an integer greater than zero.

5. The integrated circuit of claim 1 wherein said phase locked loop module comprises a Delta Sigma fractional phase locked loop module and said feedback loop parameter includes modulation of a scaling divisor.

6. The integrated circuit of claim 5 wherein said Delta Sigma fractional phase locked loop module comprises:
   a phase frequency detector module that communicates with said oscillator module and that receives said reference frequency;
   a charge pump module that communicates with said phase frequency detector module;
   a voltage controlled oscillator module that communicates with said charge pump module and that generates an output frequency;
   a scaling module that communicates with said voltage controlled oscillator and said phase frequency detector module and that selectively divides said output frequency by first and second scaling factors; and
   a Sigma Delta modulator that adjusts modulation of said scaling module between said first and second scaling factors based on said selected one of said oscillator calibrations.

7. The integrated circuit of claim 6, wherein said first and second scaling factors are divisors equal to N and N+1, where N is an integer greater than zero.

8. An integrated circuit comprising:
   temperature sensing means that senses a temperature of said integrated circuit;
   memory means for storing oscillator data relating to calibrations and for selecting one of said oscillator calibrations as a function of said sensed temperature;
   oscillator means for generating a reference signal having a frequency; and
   phase locked loop means, comprising a feedback loop having a feedback loop parameter, for selectively adjusting said feedback loop parameter based on said selected one of said oscillator calibrations.

9. The integrated circuit of claim 8 wherein said phase locked loop means comprises fractional phase locked loop means for providing feedback and said feedback loop parameter is a ratio of a scaling factor.

10. The integrated circuit of claim 9 wherein said fractional phase locked loop means comprises:
    phase frequency detector means, that communicates with said oscillator means, for receiving said reference frequency;
    charge pump means, that communicates with said phase frequency detector means, for pumping;
    voltage controlled oscillator means, that communicates with said charge pump means, for generating an output frequency;
    scaling means, that communicates with said voltage controlled oscillator and said phase frequency detector means, for selectively adjusting said output frequency first and second scaling factors, wherein said scaling means adjusts a ratio of said first and second scaling factors based on said selected one of said oscillator calibrations.

11. The integrated circuit of claim 10, wherein said first and second scaling factors are divisors equal to N and N+1, and wherein N is an integer greater than zero.
12. The integrated circuit of claim 8 wherein said phase locked loop means comprises Delta Sigma fractional phase locked loop means for providing feedback and said feedback loop parameter includes modulation of a scaling divisor.

13. The integrated circuit of claim 12 wherein said Delta Sigma fractional phase locked loop comprises:

phase frequency detector means, that communicates with said oscillator means, for receiving said reference frequency;

charge pump means, that communicates with said phase frequency detector means, for pumping;

voltage controlled oscillator means, that communicates with said charge pump means, for generating an output frequency;

scaling means, that communicates with said voltage controlled oscillator and said phase frequency detector means, for selectively dividing said output frequency by first and second scaling factors; and

Sigma Delta modulating means for adjusting modulation of said scaling means between said first and second scaling factors based on said selected one of said oscillator calibrations.

14. The integrated circuit of claim 13, wherein said first and second scaling factors are divisors equal to N and N+1, where N is an integer greater than zero.

15. A method for operating an integrated circuit comprising:

sensing a temperature of said integrated circuit;

storing oscillator data relating to calibrations;

selecting one of said oscillator calibrations as a function of said sensed temperature;

generating a reference signal having a frequency; and

selectively adjusting a feedback loop parameter of a phase locked loop based on said selected one of said oscillator calibrations.

16. The method of claim 15 wherein said feedback loop parameter is a ratio of a scaling factor.

17. The method of claim 16 further comprising:

selectively adjusting an output frequency by first and second scaling factors; and

adjusting a ratio of said first and second scaling factors based on said selected one of said oscillator calibrations.

18. The method of claim 17 wherein said first and second scaling factors are divisors equal to N and N+1, and wherein N is an integer greater than zero.

19. The method of claim 15 wherein said feedback loop parameter includes modulation of a scaling divisor.

20. The method of claim 19 further comprising:

selectively dividing said output frequency by first and second scaling factors; and

adjusting modulation between said first and second scaling factors based on said selected one of said oscillator calibrations.

21. The method of claim 20 wherein said first and second scaling factors are divisors equal to N and N+1, where N is an integer greater than zero.
