(54) Title: BATTERY COOLING PLATE AND FLUID MANIFOLD

FIG. 10

(57) Abstract: A battery cooling plate includes a first plate and a second plate that are joined together at their respective edges, and are spaced apart to define a coolant volume therebetween. Turbulating inserts can be arranged side-by-side within the coolant volume and multiple rods can extend through the turbulating inserts to at least partially define flow barriers between coolant flow channels. A fluid manifold for the battery cooling plate includes a non-planar wall that extends along a length-wise direction of the fluid manifold to separate a fluid volume into a first portion and a second portion. A series of apertures are arranged along the length-wise direction and successive ones of the apertures are fluidly connected to the first portion and to the second portion in alternating sequence.

BATTERY COOLING PLATE AND FLUID MANIFOLD

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to United States provisional patent application no. 62/694,201, filed on July 5, 2018, and to United States provisional patent application no. 62/735,236, filed on September 24, 2018, the entire contents of each of which are hereby incorporated by reference in their entirety.

BACKGROUND

[0002] Vehicles such as passenger automobiles are increasingly being electrified in order to replace or augment internal combustion engines. Such electric or hybrid-electric vehicles use electrical motors in order to provide, at least in part, the driving force for the wheels. The electrical power that is supplied to the motors is typically provided by a large number of batteries that are installed within the vehicle. Due to the large power loads associated with vehicular transport, the batteries from which such power is extracted experience substantial heating during operation and during charging. Batteries are known to be particularly sensitive to internal operating temperature, as the battery voltage will vary with the battery's internal temperature. As a result, batteries for electric vehicles often require substantial cooling during operation.

[0003] Heat exchangers for cooling heat-producing devices such as these batteries are known. These heat exchangers maintain the operating temperature of the heat-producing device within an acceptable operating range by efficiently removing the heat generated by the devices, thereby preventing degradation of the device due to excessive temperatures. Typically, the heat is removed by transfer to a fluid stream such as a coolant that is routed through plates. In such applications, it is often desirable to maintain a predominantly uniform temperature profile over the surface of the plate. Such a uniform temperature profile can be especially desirable in the cooling of batteries, particularly in applications such as electric or hybrid motor vehicle battery cooling.

[0004] These heat exchangers are sometimes presented in the form of battery cooling plates. Battery cooling plates to accomplish the requisite cooling of the batteries typically operate by supplying one or more large and generally planar surfaces against which the batteries can be disposed. A liquid (or, in some cases, two-phase liquid-vapor) coolant is

circuited through the battery cooling plate, and heat generated by the batteries is transferred through the surface into the coolant flowing through the plate, thereby reducing the temperature of the batteries to a more desirable level.

[0005] There are, however, still problems with known battery plates. Often the temperature across the cooling surface of the plate is not uniform, which causes some batteries disposed against the cooling surface or surfaces to be at a different temperature than other batteries disposed against the cooling surface or surfaces. This can result in impaired performance and/or reduced life of the batteries, since the batteries will not all be at an equal voltage and therefore will not share load equally. Among other reasons, this non-uniform surface temperature can be caused by the progressive heating of the coolant as it flows through the battery cooling plate, as well as by the presence of flow routing features formed into the otherwise flat surface of the battery cooling plate.

[0006] In order to achieve the desired uniform temperature profile, it can be advantageous to direct the flow of coolant through the heat exchanger in multiple, parallel arranged flow circuits. Such a flow circuiting requires that coolant be manifolded within the heat exchanger in order to distribute the flow of coolant to the multiple parallel flow channels as desired.

SUMMARY

[0007] A battery cooling plate includes a turbulating insert that is arranged between a first planar surface and a second planar surface, and is bonded thereto. A first coolant pass extends through the turbulating insert in a first direction, and a second coolant pass extends through the turbulating insert in a second direction that is opposite to the first direction. The first and the second coolant passes are sequentially arranged so that coolant flows first through the first pass and subsequently through the second pass. A flow barrier is arranged between the first coolant pass and the second coolant pass to prevent bypass flow between the two passes.

[0008] The flow barrier can be at least partially defined by a convolution of the turbulating insert that extends parallel to the first and the second directions, a rod that is arranged within the convolution, and a pocket that is provided within an embossment that extends from at least one of the first and second planar surfaces. An end of the rod can be

received within the pocket. The rod can be joined to the turbulating insert, to at least one of the first and second planar surfaces, and to the embossment by braze alloy.

[0009] In some embodiments, the rod can have a circular cross-section. In other embodiments, the rod can have a non-circular cross-section such as a square cross-section, a hexagonal cross-section, an octagonal cross-section, or some other shape.

[0010] The embossment can be arranged at one end of the battery cooling plate and a fluid space can be arranged at the opposite end of the battery cooling plate. The fluid space can fluidly couple the first coolant pass to the second coolant pass.

[0011] Some embodiments include a first fluid chamber and a second fluid chamber, both of which are located at the same end of the battery cooling plate. The first fluid chamber can be in fluid communication with one of the first and second coolant passes to deliver a flow of coolant thereto, and the second fluid chamber can be in fluid communication with the other of the first and second coolant passes to receive the flow of coolant therefrom. The first and second fluid chambers can be separated from each other by the embossment.

[0012] A third coolant pass can extend through the turbulating insert in either the first direction or the second direction and can be hydraulically in parallel with either the first coolant pass or the second coolant pass. A second flow barrier can be arranged between the third coolant pass and that one of the first and second coolant passes that is not hydraulically in parallel with the third coolant pass.

[0013] The second flow barrier can be similar to the first flow barrier and can be at least partially defined by a convolution of the turbulating insert that extends parallel to the first and the second directions, a rod that is arranged within the convolution, and a pocket that is provided within an embossment that extends from at least one of the first and second planar surfaces, with an end of the rod received within the pocket. The embossment of the first flow barrier and the embossment of the second flow barrier can be arranged at the same end of the battery cooling plate.

[0014] The third coolant pass and that one of the first and second coolant passes that is hydraulically in parallel with the third coolant pass can be arranged upstream of the other one of the first and second coolant passes. During operation of the battery cooling

plate, the other one of the first and second coolant passes can receive the combined flow of coolant from the third coolant pass and from that one of the first and second coolant passes. The third coolant pass and that one of the first and second coolant passes that is hydraulically in parallel with the third coolant pass can also be arranged downstream of the other one of the first and second coolant passes. During operation of the battery cooling plate, a flow of coolant from the other one of the first and second coolant passes can be distributed to the third coolant pass and to that one of the first and second coolant passes.

[0015] In at least some embodiments, the turbulating insert is one of many turbulating inserts. The rod can be arranged within aligned convolutions of the multiple turbulating inserts to at least partially define the flow barrier.

[0016] A battery cooling plate can also or alternatively include a first plate with a first planar surface and a second plate with a second planar surfaces, each of the planar surfaces extending in a length direction and a width direction. The first and the second plates can be joined together at their respective edges, and can be spaced apart to define a coolant volume therebetween. Turbulating inserts can be arranged within the coolant volume and can be joined to the first and the second planar surface. Each one of the turbulating inserts can extend over the full extent of the coolant volume in the width direction, and the turbulating inserts can be arranged side-by-side in the length direction. Multiple rods can extend through the turbulating inserts to at least partially define flow barriers between coolant flow channels that pass through the turbulating inserts.

[0017] Each one of the rods can be received within a convolution of each one of the turbulating inserts. Some or all of the rods can be joined to each one of the turbulating inserts by braze joints. In some embodiments each one of the rods has an end closest to a first end of the battery cooling plate that is received within a pocket provided within an embossment extending from at least one of the first and the second plates. In some such embodiments at least some of the rods have an end furthest from the first end of the battery cooling plate that is additionally received within a pocket provided within an embossment extending from at least one of the first and the second plates.

[0018] A first rod can at least partially define a first flow barrier and a second rod can at least partially define a second flow barrier. The first rod can have an end furthest from

the first end of the battery cooling plate that is received within a pocket provided within a first embossment and the second rod can have an end furthest from the first end of the battery cooling plate that is received within a pocket provided within a second embossment. A fluid space can extend in the width direction and can be bounded at one end by the first embossment and at another end by the second embossment. A first flow channel can be arranged adjacent the first rod, and a second flow channel can be arranged adjacent the second rod. The first and the second flow channels can both extend in the length direction, and can both be fluidly coupled to the fluid space at one end and to a common one of the inlet and outlet manifolds at an opposite end. A third flow channel can be arranged between the first flow channel and the second flow channel. The third flow channel can also extend in the length direction, and can be fluidly coupled to the fluid space at one end and to the other one of the inlet and outlet manifolds at an opposite end. A third flow barrier can be arranged between the first flow channel and the third flow channel, and a fourth flow barrier can be arranged between the second flow channel and the third flow channel. In at least some cases neither the third nor the fourth flow barrier extends into the fluid space.

[0019] A coolant inlet manifold and a coolant outlet manifold can each extend along the width direction and can each be joined to one of the first and second plates. The coolant inlet and coolant outlet manifolds can be arranged at one end of the battery cooling plate and can be in fluid communication with the coolant volume. The coolant flow channels can include a first flow channel that is fluidly connected to one of the coolant inlet manifold and the coolant outlet manifold and a second and a third flow channel that is fluidly connected to the other of the coolant inlet manifold and the coolant outlet manifold. The second and the third flow channels can be arranged on opposite sides of the first flow channel. In some such cases, one or both of the second and the third flow channels is fluidly connected to the first flow channel by a fluid space at an end of the battery cooling plate opposite the end where the coolant inlet and outlet manifolds are located.

[0020] A fluid manifold for a heat exchanger can include a planar top wall and a planar bottom wall that are spaced apart to define a fluid volume therebetween. A non-planar wall can extend along a length-wise direction of the fluid manifold between the top wall and the bottom wall to separate the fluid volume into a first portion and a second

portion. A series of apertures can be arranged along the length-wise direction and can extend through the planar bottom wall. Successive ones of the apertures along the length-wise direction can be fluidly connected to the first portion and to the second portion in alternating sequence.

[0021] In some embodiments, the centers of the apertures are arranged in a straight line that extends along the length-wise direction. In some embodiments only some of the apertures are arranged with their centers aligned along a straight line that extends along the length-wise direction.

[0022] A first fluid port can be connected to the first portion of the fluid volume and a second fluid port can be connected to the second portion of the fluid volume. In some cases at least one of the fluid ports can extend in the lengthwise direction, and in some particular cases both of the fluid ports extend in the length-wise direction. In some cases at least one of the fluid ports extends outwardly from the planar top surface, and in some particular cases both of the fluid ports extend outwardly from the planar top surface. The fluid ports can define a coolant inlet port and a coolant outlet port for the heat exchanger.

[0023] In some embodiments, the fluid manifold can be provided with fastening holes that extend through the planar top wall and through the planar bottom wall. In at least some such embodiments the fastening holes can extend through thickened portions of the non-planar wall. In some embodiments the centers of at least some of the fastening holes can be aligned with the centers of at least some of the apertures in a straight line that extends along the length-wise direction.

[0024] The fluid manifold can be constructed of a plastic material, and in at least some embodiments is constructed of at least two plastic parts that are joined together. A first one of the at least two plastic parts provides the planar top wall, and a second one of the at least two plastic parts provides the planar bottom wall. In some embodiments at least one of the fluid ports is provided by the plastic part that provides the top wall, and in some embodiments both fluid ports are provided by that part. In some embodiments at least one of the fluid ports is provided by that plastic part that provides the bottom wall, and in some embodiments both fluid ports are provided by that part. In some embodiments a portion of the non-planar wall is provided by each of the at least two plastic parts, while in other embodiments the non-planar wall is entirely provided by only

one of the plastic parts. In some embodiments the at least two plastic parts are joined together to provide a leak-free seal around an outer perimeter of the fluid manifold.

[0025] The non-planar wall of the fluid manifold can include a first non-planar surface bounding the first portion of the fluid volume, and a second non-planar surface spaced apart from the first non-planar surface and bounding the second portion of the fluid volume. A cavity can be arranged between the first and the second non-planar surfaces. In some particular cases the cavity is one of several such cavities arranged between the first and the second non-planar surfaces.

[0026] The non-planar wall can include a first set of planar wall sections and a second set of planar wall sections, the wall sections of the first set and the wall sections of the second set each extending along the length-wise direction. The first set of planar wall sections are offset to one side of the apertures, and the second set of planar wall sections are offset to the opposite side of the apertures. A third set of wall sections join ones of the first set of wall sections to ones of the second set of wall sections. In some cases, each one of the third set of wall sections is arranged between two adjacent apertures. In some cases the third set of wall sections have thickened portions, and fastening holes extend through those thickened portions.

BRIEF DESCRIPTION OF THE DRAWINGS

[0027] FIG. 1 is a perspective view of a battery cooling plate according to an embodiment of the invention.

[0028] FIG. 2 is a partially exploded perspective view of a portion of the battery cooling plate of FIG. 1.

[0029] FIG. 3 is a partial perspective view of a single plate used within the battery cooling plate of FIG. 1.

[0030] FIG. 4 is a plan view of the battery cooling plate of FIG. 1 with certain components removed to show the coolant routing through the plate.

[0031] FIG. 5 is a detail view of the portion V-V of FIG. 4.

[0032] FIG. 6 is a partial perspective view of a turbulating insert used within the battery cooling plate of FIG. 1.

[0033] FIG. 7 is a partial cross-sectional view through a flow barrier of the battery cooling plate of FIG. 1.

[0034] FIG. 8 is a partial perspective view of the battery cooling plate of FIG. 1, with select components removed for clarity.

[0035] FIG. 9 is a perspective view of the battery cooling plate of FIG. 1 with a fluid manifold according to another embodiment of the invention.

[0036] FIG. 10 is a partially exploded perspective view of the battery cooling plate of FIG. 9, with certain internal features exposed.

[0037] FIG. 11 is a top plan view of the fluid manifold shown in FIG. 9.

[0038] FIG. 12 is a partial section view of the battery cooling plate of FIG. 9.

[0039] FIG. 13 is partial view of an embodiment of a component of the fluid manifold shown in FIG. 9.

[0040] FIG. 14 is a partial view of an alternative embodiment of the fluid manifold shown in FIG. 9.

DETAILED DESCRIPTION

[0041] Before any embodiments of the invention are explained in detail, it is to be understood that the invention is not limited in its application to the details of construction and the arrangement of components set forth in the following description or illustrated in the accompanying drawings. The invention is capable of other embodiments and of being practiced or of being carried out in various ways. Also, it is to be understood that the phraseology and terminology used herein is for the purpose of description and should not be regarded as limiting. The use of “including,” “comprising,” or “having” and variations thereof herein is meant to encompass the items listed thereafter and equivalents thereof as well as additional items. Unless specified or limited otherwise, the terms “mounted,” “connected,” “supported,” and “coupled” and variations thereof are used broadly and encompass both direct and indirect mountings, connections, supports, and couplings. Further, “connected” and “coupled” are not restricted to physical or mechanical connections or couplings.

[0042] While reference is made herein to a battery cooling plate, which is a heat exchanger that is specifically adapted to cooling heat-producing batteries, it should be understood that such reference is made for exemplary purposes only. The aspects of inventions described herein can be similarly applied and be useful in other heat exchangers for cooling devices other than batteries, as well as to transfer heat between two or more fluid streams, and no limitation strictly to the cooling of batteries should be implied.

[0043] Aspects of a battery cooling plate 1 are depicted in FIGs. 1-7. The battery cooling plate 1 is constructed as a large flat plate having a broad and flat planar heat transfer surface 30 on each side, to which batteries or other electronic devices needing cooling can be mounted. While in some applications it may be desirable to mount such heat producing devices to only one of the sides 30, the battery cooling plate 1 is particularly well-suited to double-sided cooling applications.

[0044] The battery cooling plate 1 is constructed using two flat plates 2 and 3 that are bonded together at their peripheral edges. In some particularly preferable embodiments, the plates 2 and 3 are constructed from sheets of brazeable aluminum material and are joined together by brazing. In any event, it is highly desirable that the material from which the plates are constructed has a high thermal conductivity, so that the heat transfer performance of the battery cooling plate is enhanced.

[0045] While the plates 2 and 3 are referred to as flat, it should be understood that at least one of the plates has a raised periphery so that a coolant volume 4 is arranged between opposing inwardly facing planar surfaces 15, 16 of the plates 2, 3 respectively. In the exemplary embodiment of the battery cooling plate 1, the plate 2 is flat over the entirety of the plate surface, while the plate 3 has a raised periphery along the edges 13. The plates 2 and 3 are joined together at that raised periphery, which contacts the inwardly facing surface 15 of plate 2. In other embodiments, both the plates can have a raised periphery, with the peripheries of the two plates meeting to form a joining surface.

[0046] The battery cooling plate 1 is optionally provided with mounting holes 24 that can be arranged over the surface of the cooling plate. Such mounting holes 24 can be used to mount batteries or other heat producing devices to the heat transfer surfaces 30, as well as to mount the battery cooling plate 1 itself. The mounting holes 24 are fluidly

separated from the coolant volume 4, such as by being arranged in embossments 32 that extend inwardly from one or both of the plates 2, 3.

[0047] The plates 2 and 3, as well as their associated planar surfaces 15 and 16, extend in both a length direction 11 and a width direction 12. As can be seen in FIG. 1, the length direction 11 of the exemplary battery cooling plate 1 is noticeably larger in dimension than the width dimension 12 of the cooling plate. However, it should be noted that this need not be the case in all embodiments, and that “length direction” as used herein is not intended to be interpreted as the direction of the longer dimension and “width direction” as used herein is not intended to be interpreted as the direction of the shorter dimension. Rather, they are used as terms of convenience for describing the arrangement of fluid flows through the cooling plate 1, as will be described hereafter.

[0048] The battery cooling plate 1 is further provided with a coolant inlet manifold 7 and a coolant outlet manifold 8, each of which extend along the width direction 12 and each of which are arranged at a first end 9 of the cooling plate 1 in the length direction 11. The coolant inlet manifold 7 and the coolant outlet manifold 8 are arranged side by side at the end 9, and are fluidly connected to the coolant volume 4 within the battery cooling plate 1. As can be seen in the partially exploded view of FIG. 2, the plate 2 is provided with a first series of flanged apertures 28 and a second series of flanged apertures 29, the apertures of each series being in a linear arrangement. The manifolds 7 and 8 are provided with receiving apertures (not shown) that correspond to the flanged apertures 28 and 29, respectively. The manifolds 7, 8 are joined to the plate 2 (preferably during the same joining operation that joins the plates 2 and 3 together) in order to create the aforementioned fluid connections.

[0049] The coolant inlet manifold 7 is provided with an inlet port 22, and the coolant outlet manifold 8 is provided with an outlet port 23. The battery cooling plate 1 can be operatively coupled to a coolant system that directs a flow of liquid coolant into the battery cooling plate 1 at a first temperature through the inlet port 22, and that receives the flow of liquid coolant from the battery cooling plate at a second temperature higher than the first temperature through the outlet port 23. In this manner, the battery cooling plate 1 can be used within a thermal management system to remove heat that is generated within batteries that are mounted to the heat transfer surface(s) 30 of the plate 1, thereby maintaining the batteries within a suitable operating temperature range. It should be

noted that, while the plate 1 is referred to herein as a battery cooling plate, it can also be used to heat batteries that are mounted to the plate. By way of example, in very cold ambient temperature conditions the batteries might benefit from being elevated in temperature in order to be within the desired operating temperature range. Under such conditions, it is possible for the plate 1 to be used to transfer heat from a heated flow of coolant that is circulated through the coolant volume 4 to the batteries mounted to the heat transfer surface(s) 30. It should further be noted that the plate 1 is not limited to cooling and/or heating batteries, but can also be used to transfer heat to or from other devices that can be mounted to the heat transfer surface(s) 30.

[0050] In order to enhance the heat transfer effectiveness of the battery cooling plate 1, turbulating inserts 5 are located within the coolant volume 4. As can be seen in FIG. 4, multiple turbulating inserts 5 are preferable provided in order to completely fill the coolant volume 4. While in some circumstances (such as when the battery cooling plate 1 is of a particularly small dimension) a single turbulating insert 5 may be used, in most cases it will be preferable to use multiple turbulating inserts 5 due to difficulties in producing a single turbulating insert of sufficient size.

[0051] An exemplary turbulating insert that is particularly well-suited for use within the battery cooling plate 1 is depicted in FIG. 6. This turbulating insert 5 is of a lanced and offset variety, and is typically produced from a thin sheet of metal material that is directed through a fin machine, wherein it is formed by stamping and/or rolling operations. The sheet of material typically enters the fin machine having been pre-slit to a width dimension (extending in the direction indicated by the double-ended arrow 25), and is fed through the machine in the direction indicated by the double-ended arrow 26. The forming of the sheet material produces convolutions 17 that extend in the direction 25. Along that direction, the material is lanced and is then offset in alternately opposing directions parallel to the sheet feed direction 26, thereby creating a series of apertures 27 along each convolution 17. The apertures 27 allow for fluid flow between adjacent convolutions 17, so that the turbulating insert 5 is porous to fluid flow in both the direction 25 and the direction 26. It should be recognized that a fluid will flow more easily along the length of the corrugations 17 (i.e. in the direction 25) than perpendicular to the length of the corrugations 17 (i.e. in the direction 26). Consequently, the direction

25 is often referred to as the “low pressure-drop direction” and the direction 26 is often referred to as the “high pressure-drop direction”.

[0052] The sheet of material from which the turbulating inserts 5 are formed is typically provided in spool form, allowing for a sheet of great length. Consequently, the turbulating inserts 5 can be provided with a dimension in the direction 26 that is practically unlimited. In contrast, the dimension of the turbulating inserts in the direction 25 is limited by the size of the fin machine, as well as by the forces required for the forming operations, which typically are performed on an entire convolution 17 at a time. The turbulating inserts 5 are therefore provided with a dimension in the high-pressure drop direction 26 that is sufficient to extend over the full extent of the coolant volume 4 in the direction 12. The turbulating inserts are arranged side-by-side along the direction 11 in order to extend over the full extent of the coolant volume 4 in that direction. By arranging the turbulating inserts in this manner, the low pressure-drop direction 25 of the turbulating inserts 5 is aligned with the direction 11, so that fluid flowing through the coolant volume 4 can be easily directed between the ends 9 and 10 of the battery cooling plate 1.

[0053] The fluid flow through the coolant volume 4 is illustrated by the use of arrows in FIGs. 4 and 5. The flow is directed through multiple flow paths arranged to be hydraulically in parallel, each encompassing two passes through the coolant volume 4. The first pass of each flow path extends from the end 9 of the battery cooling plate 1 to the end 10, and the second pass of each flow path extends from the end 10 back to the end 9. Each pass is provided by a flow channel 14 that extends successively through each one of the turbulating inserts 5 in the direction 25. Spaces 33 are provided at the end 10 of the battery cooling plate 1 to hydraulically connect each one of the flow channels 14 to at least one, and sometimes two, adjacent flow channels 14. Adjacent flow channels 14 are hydraulically separated from one another along the length direction 25 of the coolant volume 4, other than at the spaces 33, by way of flow barriers 6.

[0054] Each of the flow channels 14 begins or terminates at the end 9 of the battery cooling plate 1 in a fluid chamber 31. The fluid chambers 31 are arranged directly below the coolant inlet and outlet manifolds 7, 8. Along the direction 26, the fluid chambers 31 are fluidly coupled to the coolant inlet manifold 7 and the coolant outlet manifold 8 in alternating sequence, by way of the flanged apertures 28 and 29, respectively. As a

result, the flow channels 14 direct fluid from the end 9 towards the end 10 and from the end 10 towards the end 9 in alternating sequence along the width of the plate 1.

[0055] The fluid chambers are separated from one another, and are at least partially defined, by embossments 19 that extend from at least one of the plates 2, 3. The embossments 19 each extend from the edge 9 of the cooling plate 1 to the nearest one of the turbulating inserts 5, and preferably about the end of the turbulating insert 5.

[0056] As depicted in FIG. 4, some of the flow channels 14 receive fluid flow from both adjacent channels 14, and some other of the flow channels 14 direct fluid flow to both adjacent channels 14. Those flow channels 14 that receive flow from, or direct flow to, two other channels 14 are preferably twice as large in the direction 26 as their adjacent channels 14, so that the amount of fluid flow per cross-sectional area of the flow channels 14 is approximately constant.

[0057] The flow barriers 6 are arranged between adjacent flow channels 14 in order to prevent the undesirable bypass of fluid flow between adjacent channels, other than at the spaces 33. Each flow barrier 6 is at least partially defined by a rod 18 that is received within a convolution of each one of the turbulating inserts 5. The rods 18 extend continuously in the length direction 11 over most, and in some case all, of the length of the flow channels 14. The end 21 of each rod 18 is received within a pocket 20, each of the pockets 20 being provided within an embossment 19.

[0058] The size of the rod 18 is preferably such that is approximately equal to the height of the coolant channel 4 minus the thickness of the sheet material for the turbulating inserts 5, as can be seen in the sectional view of FIG. 7. Furthermore, the convolutions 17 are preferably sized so that a rod 18 can be nestled between the opposing offsets at either side of the convolution 17, as also shown in FIG. 7. In this manner, the rods 18 can be securely retained in position during the assembly of the battery cooling plate 1. The pockets 20 can likewise be sized to precisely and securely retain the ends 21 of the rods 18. While the rods 18 of the exemplary embodiment are circular in cross-section, in other embodiments the rods may have a different, non-circular cross-section. By way of example only, the rod cross-section can be square, rectangular, triangular, hexagonal, octagonal, etc.

[0059] Additional embossments 19 with pockets 20 are provided adjacent the end 10 of the battery cooling plate 1, and can be used to separate adjacent ones of the spaces 33. The number of such embossments at the end 10 is preferably less than the number of embossments 19 at the end 9, so that the locations of the pockets 20 at the end 10 correspond to less than all of the flow barriers 6. The rods 18 of those flow barriers 6 that do correspond to the locations of the pockets 20 at the end 10 are longer in length, such that an end of those rods opposite the ends 21 are also received within those pockets 20, thereby extending those flow barriers 6 to the full length of the coolant volume 4 in the direction 11.

[0060] The components that define each flow barrier 6 are preferably joined together during a brazing of the battery cooling plate 1 in order to create a predominantly fluid-tight flow barrier 6. In some embodiments this joining can be accomplished by providing a layer of braze alloy cladding on the surfaces of one or more of the components, such as (for example) the rods 18, the turbulating inserts 5, the plates 2 and/or 3, etc. In some embodiments the joining can also or alternatively be provided by braze alloy in a paste form that is applied to the rods 18 prior to their insertion into the assembly.

[0061] Forming the flow barriers 6 in this manner is advantageous over forming flow barriers by deforming one or both of the plates 2, 3 to define flow barriers. Forming flow barriers out of the plate surfaces has the undesirable effect of reducing the available surface area to which heat from the batteries mounted to the plates can be rejected. Furthermore, the forming operations required to produce flow barriers that extend over plates having a long dimension in the flow barrier can be difficult and expensive, leading to increased cooling plate cost.

[0062] By separating the coolant volume 4 into the series of flow channels 14, a more uniform temperature profile can be achieved over the heat transfer surface(s) 30. Along the width direction 12, a uniform temperature profile is achieved by the separation of the coolant volume 4 in that direction into multiple flow paths, each of which are hydraulically in parallel. Along the length direction 11, a uniform temperature profile is achieved through the averaging effect that is achieved by having coolant that is progressively further from the inlet manifold 7 in each of the first passes being immediately adjacent to coolant that is progressively further from the outlet manifold 8 in each of the second passes. Since the coolant is heated by the batteries as it passes along

the flow path during the operation of the cooling plate 1, thereby continuously increasing in temperature along the flow path, such an arrangement allows for an averaging of the temperature of the heat transfer surface 30 that is fairly uniform along the direction 11.

[0063] FIGs. 9 and 10 depict a battery cooling plate 101 that is similar in construction to the battery cooling plate 1 described earlier. The battery cooling plate 101 includes a single fluid manifold 51 to replace the separate coolant inlet manifold 7 and coolant outlet manifold 8 of the battery cooling plate 1. It should be understood that, while the fluid manifold 51 may be especially advantageous when applied as a portion of a plate style heat exchanger 101 as shown, it can also be used with a wide variety of heat exchanger styles and types and is not limited to use solely as part of a battery cooling plate.

[0064] The fluid manifold 51 is joined to the top plate 2 of the battery cooling plate 101 in order to deliver the coolant to, and to receive the coolant from, the coolant volume 4. The fluid manifold 51 is arranged at one end of the battery cooling plate 101 and extends along that end of the battery cooling plate 101 in a length-wise direction 60 of the fluid manifold 51, the length-wise direction being generally aligned with the width direction 12 of the battery cooling plate. The fluid manifold 51 includes a top wall 57 and a bottom wall 58, between which is disposed a fluid volume 54. A non-planar wall 59 extends between the top wall 57 and the bottom wall 58, and divides the fluid volume 54 into a first portion 55 and a second portion 56. The non-planar wall 59 extends along the length-wise direction 60 in a meandering fashion in order to provide separation between the first and second portions 55 and 56 of the fluid volume 54.

[0065] As previously described with reference to FIG. 4, and as shown again in FIG. 10, the coolant volume 4 of the battery cooling plate 101 is divided into a series of parallel arranged sections by flow barriers 6 that extend along a length of the battery cooling plate 101 in a direction that is perpendicular to the length-wise direction 10 of the fluid manifold 51. The flow barriers 6 can be provided as separate barrier pieces that are assembled into the formed plate 102, or alternatively can be formed into the plate 102 or into the plate 101. The previously-described turbulating flow inserts 5 can optionally be placed into the fluid space 104 between the flow barriers 106.

[0066] As also previously described with reference to FIG. 4, and as shown again in FIG. 10, the direction of the fluid flow through adjacent ones of the parallel arranged

sections of the battery cooling plate 101 alternates between flowing away from and flowing towards the fluid manifold 51. Although not shown in the FIG. 10, at the end of the battery cooling plate 101 opposite the fluid manifold 51, at least some of the flow barriers 6 terminate prior to the end of the battery cooling plate 101 so that the coolant flowing through each one of the parallel arranged sections wherein the coolant is directed away from the fluid manifold 51 can be redirected to flow through an adjacent one of the parallel arranged sections wherein the coolant flows back to the fluid manifold 51, as seen in FIG. 4.

[0067] In the exemplary embodiment, some of the parallel arranged sections have a flow width (as measured along the length-wise direction 60 of the fluid manifold 51) that is wider than the flow width of adjacent sections, and particularly approximately twice the width of those adjacent sections. Those wider sections can be hydraulically connected to be in series with both of the adjacent sections, so that coolant flowing away from the fluid manifold 51 through the wider sections is divided among the two immediately adjacent narrower sections and flows back to the fluid manifold 51 along those two sections, and so that coolant flowing towards the fluid manifold 51 through the wider sections is the combined flow of coolant from the two immediately adjacent narrower sections. It should be understood, however, that the width of the sections can vary in an alternative manner, or can be uniform along the entire battery cooling plate 101.

[0068] Flowing the coolant through the battery cooling plate 101 along multiple parallel arranged sections in this manner can provide certain advantages, especially when the battery cooling plate 101 is used as a battery cooling plate. Greater temperature uniformity over the cooling surface of the top plate 101 can be achieved with such a flow configuration, both in comparison to multiple sequentially arranged passes through the battery cooling plate 101 and in comparison to a single two-pass circuit. Such greater temperature uniformity is known to improve the performance and the durability of the batteries being cooled by the cooling plate.

[0069] A series of flanged holes 103, similar to the flanged apertures 28 and 29, is provided within the top plate 101 directly below the fluid manifold 51. Each of the flanged holes 103 corresponds to one of the parallel arranged sections of the fluid space 104. As best seen in the detail view of FIG. 4, each of the flanged holes 103 additionally corresponds to one of a series of apertures 61 that extend through the planar bottom wall

58 of the fluid manifold 51. The apertures 61 are preferably sized so that the flange of the hole 103 can extend at least partially into the aperture 11, thereby facilitating the alignment of the fluid manifold 51 to the top plate 2 of the battery cooling plate 101. In other alternative embodiments, the holes 103 can be provided without flanges, and other alignment features can be incorporated into the top plate 2 or into the fluid manifold 51 or both.

[0070] The series of apertures 61 are, in the exemplary embodiment, arranged so that their centers are aligned in a straight line extending along the length-wise direction 60 of the fluid manifold. The non-planar wall 59 is arranged so that the apertures 61 are alternately arranged on opposing sides of the wall 59. In this manner, successive ones of the apertures 61 are alternately in fluid communication with the portion 55 and with the portion 56 of the fluid volume 54. As a result, the holes 103 and their corresponding portions of the coolant volume 4 within the battery cooling plate 101 are also alternately coupled to the portions 55 and 56.

[0071] The fluid manifold 51 is further provide with a pair of fluid ports 22, 23 that function similarly to the like-numbered ports of the embodiment of FIG. 2. In the exemplary embodiment of FIGs. 9 and 10, the fluid ports 22, 23 are both provided as part of the top wall 57 of the manifold, although other arrangements of the fluid ports can be contemplated. The fluid port 22 provides fluid communication with the portion 55 of the fluid volume 4, and the fluid port 23 provides fluid communication with the portion 56. The fluid port 22 thus functions as a fluid inlet port for the battery cooling plate 101 when the heat exchanger is coupled into a thermal system, while the fluid port 23 functions as a fluid outlet port for the battery cooling plate 101. During operation of the battery cooling plate 101, a flow of liquid coolant is received into the inlet port 22, and is directed by way of the corresponding portion 55 of the fluid volume 54 to flow through portions of the coolant volume 4 in a direction away from the fluid manifold 51. The flow of liquid coolant is subsequently directed back to the fluid manifold 51 through other portions of the coolant volume, and is received into the portion 56 of the fluid volume 54 of the fluid manifold 51 and is removed by way of the outlet port 23.

[0072] Particularly, the non-planar wall 59 includes a first set of wall sections 65 that extend in the length-wise direction 60 and that are offset to one side of the apertures 61, and a second set of wall sections 66 that extend in the length-wise direction 60 and that

are offset to the opposite side of the apertures 61. A third set of wall sections 67 extend between ends of the wall sections 65 and ends of the wall sections 66 to join the sections together into the continuous non-planar wall 59. Each one of the third set of wall sections 67 is located between two adjacent ones of the apertures 61. As a result, the non-planar wall 59 defines a first non-planar surface 68 that extends the entire length of the fluid manifold 51 and that bounds the portion 56 of the fluid volume 54, and a second non-planar surface 69 that also extends the entire length of the fluid manifold 51 and that bounds the portion 55 of the fluid volume 54. The surfaces 68 and 69 are spaced apart by the thickness of the non-planar wall 59.

[0073] The fluid manifold 51 can be constructed of several plastic parts that are joined together prior to assembly to the top plate 2. In the exemplary embodiment of FIGs. 9-12, the fluid manifold 51 includes a first part 52 that provides the top wall 57, and a second part 53 that provides the bottom wall 58. The non-planar wall 89 is provided in part by the first part 52, and in part by the second part 53. In other embodiments, the non-planar wall 59 can be provide entirely by only one of the parts 52, 53. The plastic parts 52, 53 are joined together by gluing, hot plate welding, vibration welding, ultrasonic welding, or other known techniques for joining together plastic parts. In this manner, a leak-free seal is provided around an outer perimeter of the fluid manifold 51 to prevent the undesirable leakage of coolant from the fluid manifold 51 during operation of the battery cooling plate 101. A leak-free internal seal between the portions 55 and 56 of the fluid volume 54 can simultaneously be created to prevent the coolant from passing between the portions 55, 56 without passing through the coolant volume 4.

[0074] By constructing the fluid manifold 51 from a low thermal conductivity plastic material, the undesirable transfer of heat through the non-planar wall 59 between the coolant in the first portion 54 and the coolant in the second portion 56 can be reduced. In some particular embodiments, such as the embodiment depicted in FIG. 13, the non-planar wall 59 can additionally be provided with a cavity 70 between the surfaces 68 and 69 along at least some portions of the non-planar wall 59 to further reduce this undesirable transfer of heat.

[0075] The fluid manifold 51 can be mechanically secured to the plates 2, 3 by way of mechanical fasteners such as rivets 109. The rivets 109 extend through fastening holes 63 that are provided by the fluid manifold 51, and further extend through corresponding

holes provided in the plates 2, 3. The fastening holes extend continuously through the fluid manifold 51 from the top wall 57 to the bottom wall 58. Thickened portions 64 of the non-planar wall 59 can be provided at the locations of the fastening holes 63, so that the holes 63 can be fluidly isolated from the fluid volume 54, thereby preventing the leakage of coolant from the fluid manifold 51 through the fastening holes 63.

[0076] In order to prevent leakage of the coolant at the joint between the fluid manifold 51 and the top plate 2, a gasket 108 can be arranged between the manifold and the top plate. The gasket 108 can be provided with openings at the locations of the apertures 61 and the flanged holes 103 to allow for the passage of coolant through the gasket 108, and can have compressible regions surrounding those openings. As the fluid manifold 51 is assembled to the top plate 2 by the rivets 109, the compressible portions of the gasket 108 are compressed between the bottom wall 58 of the fluid manifold 51 and the top plate 2, thereby creating a fluid-tight seal to prevent coolant leakage.

[0077] It should be understood that the rivets 109 depict only one potential type of fastening means for securing the fluid manifold to the plates 2, 3. Various other alternative types of mechanical fasteners such as screws, clips, etc. could alternatively be used to achieve a similar result. In some embodiments it may be desirable to incorporate at least a portion of the fastener into the plates 2 or 3, such as by way of a stud that extends up from the plates. In still other embodiments the fastener can be incorporated into one of the parts of the fluid manifold 51 itself, such as heat staking bosses that project from the bottom wall 58 and that are thermoplastically deformed to secure the fluid manifold 51 to the plates 2, 3.

[0078] FIG. 14 depicts an alternative embodiment 201 of the fluid manifold, constructed of a first plastic part 202 joined to a second plastic part 203. In the alternative embodiment 201, the first part 202 has been simplified to a flat part providing the top wall 207 (including the fastening holes 213), and the majority of the features, including the bottom wall 208, the fluid ports 222 and 223, and the non-planar wall (not shown) are provided by the second part 203. Such an embodiment can allow for lower manufacturing costs by having only the second part 203 be an injection-molded plastic part, with first part 202 being produced by simpler methods such as stamping.

[0079] It should be understood that various aspects of the different embodiments can be combined. By way of example, the embodiment of FIG. 9 shows both fluid ports extending outwardly from the part containing the top wall, whereas the embodiment of FIG. 14 shows both fluid ports extending in the lengthwise direction from the part containing the bottom wall. In some embodiments it may be preferable to have one fluid port provided by the part containing the top wall and extending perpendicular to the top wall, and to have the other fluid port provided by the part containing the bottom wall and extending in the lengthwise direction.

[0080] Various alternatives to the certain features and elements of the present invention are described with reference to specific embodiments of the present invention. With the exception of features, elements, and manners of operation that are mutually exclusive of or are inconsistent with each embodiment described above, it should be noted that the alternative features, elements, and manners of operation described with reference to one particular embodiment are applicable to the other embodiments.

[0081] The embodiments described above and illustrated in the figures are presented by way of example only and are not intended as a limitation upon the concepts and principles of the present invention. As such, it will be appreciated by one having ordinary skill in the art that various changes in the elements and their configuration and arrangement are possible without departing from the spirit and scope of the present invention.

What is claimed is:

1. A battery cooling plate comprising:
 - a turbulating insert arranged between a first planar surface and a second planar surface and bonded thereto;
 - a first coolant pass extending through the turbulating insert in a first direction;
 - a second coolant pass extending through the turbulating insert in a second direction opposite the first direction, the first and the second coolant passes being sequentially arranged; and
 - a flow barrier arranged between the first coolant pass and the second coolant pass to prevent bypass flow between the first and second coolant passes, the flow barrier being at least partially defined by:
 - a convolution of the turbulating insert extending parallel to the first and the second directions;
 - a rod arranged within the convolution; and
 - a pocket provided within an embossment extending from at least one of the first and the second planar surfaces, an end of the rod being received within the pocket.
2. The battery cooling plate of claim 1, wherein the rod is joined to the turbulating insert, to one of the first and second planar surfaces, and to the embossment by braze alloy.
3. The battery cooling plate of claim 1, wherein an end of the turbulating insert abuts the embossment.
4. The battery cooling plate of claim 1, wherein the rod has a circular cross-section.
5. The battery cooling plate of claim 1, wherein the embossment is arranged at a first end of the battery cooling plate, further comprising a fluid space arranged at a second end of the battery cooling plate opposite the first end to fluidly couple the first coolant pass to the second coolant pass.

6. The battery cooling plate of claim 1, further comprising a first fluid chamber arranged at a first end of the battery cooling plate and in fluid communication with one of the first and the second coolant passes to deliver a flow of coolant to that one of the first and the second coolant passes, and a second fluid chamber arranged at the first end of the battery cooling plate and in fluid communication with the other of the first and the second coolant passes to receive the flow of coolant from that other of the first and the second coolant passes, the first fluid chamber and the second fluid chamber being separated from each other by the embossment.
7. The battery cooling plate of claim 1 wherein the flow barrier is a first flow barrier, further comprising:
 - a third coolant pass extending through the turbulating insert in one of the first and second directions, the third coolant pass being hydraulically in parallel with one of the first and second coolant passes; and
 - a second flow barrier similar to the first flow barrier arranged between the third coolant pass and that one of the first and the second coolant passes that is not hydraulically in parallel with the third coolant pass.
8. The battery cooling plate of claim 7, wherein the embossment of the first flow barrier and the embossment of the second flow barrier are arranged at a same end of the battery cooling plate.
9. The battery cooling plate of claim 7, wherein the third coolant pass and that one of the first and second coolant passes that is hydraulically in parallel with the third coolant pass are arranged upstream of the other one of the first and second coolant passes, the other one of the first and second coolant passes receiving the combined flow of coolant from the third coolant pass and from that one of the first and second coolant passes.
10. The battery cooling plate of claim 1 wherein the turbulating insert is one of plurality of inserts, the rod being arranged within aligned convolutions of the plurality of inserts to at least partially define the flow barrier.

11. A battery cooling plate comprising:

a first plate providing a first planar surface extending in a length direction and in a width direction;

a second plate joined to the first plate at edges thereof, the second plate providing a second planar surface extending in the length direction and in the width direction, the first and second planar surfaces being spaced apart to define a coolant volume therebetween;

a plurality of turbulating inserts arranged within the coolant volume and joined to the first and the second planar surfaces, each of the plurality of turbulating inserts extending over the full extent of the coolant volume in the width direction, the plurality of turbulating inserts being arranged side-by-side in the length direction; and

a plurality of rods, each extending through the plurality of turbulating inserts, to at least partially define flow barriers between coolant flow channels that pass through the plurality of turbulating inserts.

12. The battery cooling plate of claim 11, wherein each one of the plurality of rods is received within a convolution of each one of the plurality of turbulating inserts.

13. The battery cooling plate of claim 11, wherein each one of the plurality of rods is joined to each one of the plurality of turbulating inserts by braze joints.

14. The battery cooling plate of claim 11, wherein each one of the plurality of rods has an end closest to a first end of the battery cooling plate that is received within a pocket provided within an embossment extending from at least one of the first and the second plates.

15. The battery cooling plate of claim 14, wherein at least some of the plurality of rods have an end furthest from the first end of the battery cooling plate that is additionally received within a pocket provided within an embossment extending from at least one of the first and the second plates.

16. The battery cooling plate of claim 16, wherein the plurality of rods includes a first rod at least partially defining a first flow barrier and a second rod at least partially defining a second flow barrier, the first rod having an end furthest from the first end of the battery cooling plate that is received within a pocket provided within a first embossment and the second rod having an end furthest from the first end of the battery cooling plate that is received within a pocket provided within a second embossment, further comprising:

- a fluid space extending in the width direction and bounded at one end by the first embossment and at another end by the second embossment;

- a first flow channel adjacent the first rod, the first flow channel extending in the length direction and being fluidly coupled to the fluid space at one end and to one of the inlet and outlet manifolds at an opposite end;

- a second flow channel adjacent the second rod, the second flow channel extending in the length direction and being fluidly coupled to the fluid space at one end and to said one of the inlet and outlet manifolds at an opposite end;

- a third flow channel arranged between the first flow channel and the second flow channel, the third flow channel extending in the length direction and being fluidly coupled to the fluid space at one end and to the other one of the inlet and outlet manifolds at an opposite end;

- a third flow barrier arranged between the first flow channel and the third flow channel;
- and

- a fourth flow barrier arranged between the second flow channel and the third flow channel, wherein the third flow barrier and the fourth flow barrier do not extend into the fluid space.

17. The battery cooling plate of claim 11, further comprising a coolant inlet manifold and a coolant outlet manifold each extending along the width direction and each joined to one of the first and second plates, both the coolant inlet manifold and the coolant outlet manifold being arranged at a first end of the battery cooling plate in the length direction and both being fluidly communicative with the coolant volume, wherein the coolant flow channels include a first flow channel fluidly connected to one of the coolant inlet manifold and the coolant outlet manifold and a second and a third flow channel fluidly connected to the other of the coolant inlet manifold and the coolant outlet manifold, the second and the third flow channels being arranged on opposite sides of the first flow channel.

18. The battery cooling plate of claim 17, wherein at least one of the second and the third flow channels is fluidly connected to the first flow channel by a fluid space at an end of the battery cooling plate opposite the first end in the length direction.

19. The battery cooling plate of claim 18, wherein both the second and the third flow channels are fluidly connected to the first flow channel by a fluid space at an end of the battery cooling plate opposite the first end in the length direction.

20. The battery cooling plate of claim 19, wherein the fluid space is one of a plurality of fluid spaces that are aligned in the width direction, adjacent ones of the plurality of fluid spaces being separated from each other by one of the flow barriers.

21. A fluid manifold for a heat exchanger, comprising:
- a planar top wall and a planar bottom wall spaced apart to define a fluid volume therebetween;
 - a non-planar wall extending along a length-wise direction of the fluid manifold between the planar top wall and the planar bottom wall to separate the fluid volume into a first portion and a second portion;
 - a first fluid port connected to the first portion of the fluid volume and a second fluid port connected to the second portion of the fluid volume;
 - a plurality of apertures arranged along the length-wise direction and extending through the planar bottom wall, successive ones of the plurality of apertures along the length-wise direction being fluidly connected to the first portion and to the second portion in alternating sequence.
22. The fluid manifold of claim 21, wherein the first fluid port is a coolant inlet port and wherein the second fluid port is a coolant outlet port.
23. The fluid manifold of claim 21, wherein the first fluid port and the second fluid port both extend outward from the planar top wall.
24. The fluid manifold of claim 21, wherein at least one of the first fluid port and the second fluid port extends in the length-wise direction.
25. The fluid manifold of claim 21, further comprising a plurality of fastening holes extending through the planar top wall and the planar bottom wall.
26. The fluid manifold of claim 25, wherein the plurality of fastening holes extend through thickened portions of the non-planar wall.
27. The fluid manifold of claim 21, wherein the fluid manifold is constructed of a plastic material.

28. The fluid manifold of claim 27, comprising a first plastic part that provides the planar top wall and a second plastic part that provides the planar bottom wall.

29. The fluid manifold of claim 28, wherein at least one of the first and second fluid ports is provided by the first plastic part.

30. The fluid manifold of claim 28, wherein at least one of the first and second fluid ports is provided by the second plastic part.

31. The fluid manifold of claim 28, wherein a first portion of the non-planar wall is provided by the first plastic part and a second portion of the non-planar wall is provided by the second plastic part.

32. The fluid manifold of claim 28, wherein the first plastic part and the second plastic part are joined together to provide a leak-free seal around an outer perimeter of the fluid manifold.

33. The fluid manifold of claim 21, wherein the non-planar wall includes a first non-planar surface bounding the first portion of the fluid volume, a second non-planar surface spaced apart from the first non-planar surface and bounding the second portion of the fluid volume, and a cavity arranged between the first non-planar surface and the second non-planar surface.

34. The fluid manifold of claim 21, wherein the centers of the plurality of apertures are arranged in a straight line extending along the length-wise direction.

35. The fluid manifold of claim 34, wherein the centers of the fastening holes are aligned with the straight line in which the centers of the plurality of apertures are arranged.

36. The fluid manifold of claim 21, wherein the non-planar wall includes a first plurality of planar wall sections extending along the length-wise direction and offset to one side of the plurality of apertures, a second plurality of wall sections extending along the length-wise direction and offset to another side of the plurality of apertures, and a third plurality of wall sections joining ones of the first plurality of wall sections to ones of the second plurality of wall sections.

37. The fluid manifold of claim 36, wherein each one of the third plurality of wall sections is arranged between two adjacent ones of the plurality of apertures.

38. The fluid manifold of claim 36, further comprising a plurality of fastening holes extending through thickened portions of the third plurality of wall sections.

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:
 -*- See extra sheet -*-

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-20

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- ☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- ☐ No protest accompanied the payment of additional search fees.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US 9,065,158 B2 (Martz) 23 June 2015 (23.06.2015), entire document, especially Fig. 4, col. 4 ln. 33-35	1-20
A	US 2013/0171491 A1 (Wei) 04 July 2013 (04.07.2013), entire document	1-20
A	US 9,627,724 B2 (LG Chem) 18 April 2017 (18.04.2017), entire document	1-20
A	US 2017/0324132 A1 (Dana Canada Corporation) 09 November 2017 (09.11.2017), entire document	1-20
A	US 2018/0166754 A1 (LG Chem, Ltd.) 14 June 2018 (14.06.2018), entire document	1-20

☐ Further documents are listed in the continuation of Box C.☐ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 19/40138

-*- Box III - Observations where unity of invention is lacking -*-

This application contains the following inventions or groups of inventions which are not so linked as to form a single general inventive concept under PCT Rule 13.1. In order for all inventions to be searched, the appropriate additional search fees must be paid.

Group I: Claims 1-20 directed to a battery cooling plate comprising a plurality of turbulating inserts and a plurality of rods.

Group II: Claim 21-38 directed to a fluid manifold comprising a planar top wall, a planar bottom wall, a non-planar wall, a first fluid port, a second fluid port, and a plurality of apertures.

The inventions listed as Groups I-VI do not relate to a single general inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons:

SPECIAL TECHNICAL FEATURES

The invention of Group I includes the special technical features of a battery cooling plate having a plurality of turbulating inserts to be joined to a first and second planar surface and a plurality of rods extending through the plurality of turbulating inserts.

The invention of Group II includes the special technical features of a fluid manifold having a planar top wall, a planar bottom wall, a non-planar wall, a first fluid port, a second fluid port, and a plurality of apertures.

COMMON TECHNICAL FEATURES

Groups I and II do not share any common technical features.

As the common technical features were known in the art at the time of the invention, these cannot be considered special technical feature that would otherwise unify the groups.

Therefore, Groups I-VI lack unity under PCT Rule 13 because they do not share a same or corresponding special technical feature.
