GOVERNMENT SUPPORT

[0002] This invention was made with government support under grant number W81XWH-14-2-0171 awarded by the United States Army Medical Research and Materiel Command. The government has certain rights in the invention.

BACKGROUND OF THE INVENTION

[0003] The most widely distributed kinetoplastid order are the *Leishmania*, which infect individuals in sub-tropical climates around the globe, including Asia, the Middle East, Africa, southern Europe, Central and South America. Diseases caused by *Leishmania* species range from relatively mild and ultimately self-resolving cutaneous leishmaniasis, through disfiguring mucocutaneous leishmaniasis to the potentially fatal visceral leishmaniasis. Since 2005, cutaneous leishmaniasis has been identified as a problem for military forces participating in conflicts in Afghanistan and Iraq. Mucocutaneous leishmaniasis is widely distributed in both southern Europe and the Americas, and represents a significant health problem, particularly in children. The most serious disease caused by *Leishmania* parasites, visceral leishmaniasis (VL), is most prevalent in India and eastern Africa, and significant mortality continues to be an issue in these areas.

[0004] Global incidence of symptomatic leishmaniasis is estimated at 2 million cases per year and is rapidly increasing, making leishmaniasis a top priority for the tropical disease program of the World Health Organization. Of the 2 million new cases of leishmaniasis that occur each year, approximately three-quarters are cases of cutaneous leishmaniasis (CL). Although CL does not result in death; the true socioeconomic impact of cutaneous leishmaniasis is difficult to quantify. Severe disfigurement, disability, and social/psychological stigma often results from CL infections.

[0005] Prevention of CL and VL is limited to personal protective measures such as insect repellent, bed nets, and control of disease reservoirs such as rodents and dogs; no chemoprophylactic or vaccine options are available. Treatment options for CL and VL are similarly limited. The drugs traditionally used to treat leishmaniasis, such as pentavalent antimony, pentamidine, and amphotericin B, have variable efficacy, due in part to resistance, and occasionally produce severe side effects. Newer agents such as nitroimidazoles, miltefosine, paromomycin (injectable and topical), and liposomal amphotericin B are either difficult to use or expensive.

[0006] Chagas disease, caused by the parasite *Trypanosoma cruzi*, is widely distributed across Central and South America, and is considered the leading infectious cause of cardiomyopathy and death due to parasitic infection in the western hemisphere. It is estimated that over 7 million individuals are infected with *T. cruzi* parasites, and over 100 million are at risk. The estimated global burden of the disease is 649,000 disability adjusted life years (the number of healthy years of life lost due to premature death and disability). Causing about 14,000 deaths annually, Chagas disease kills more people in Latin America than any other parasitic disease, including malaria. With continued global warming, northward expansion of *T. cruzi* infections into the United States has been observed. A particular challenge of Chagas disease is that the acute symptoms are relatively minor, such that the majority of patients are undiagnosed for decades; only 30% of chronically infected individuals will develop cardiovascular disease.

[0007] Trypanosomatids are a group of kinetoplastid protozoa distinguished by having only a single flagellum. Trypanosomatids are responsible for diseases such as South American trypanosomiasis (Chagas Disease) and African Animal Trypanosomosis (AAT).

[0008] *T. cruzi* is transmitted by various insect vectors that belong to the Reduviidae family. Transmission to humans is dependent on living conditions as these insects inhabit houses of mud and thatch which are common in lower socioeconomic areas. Infection may also be acquired by consuming contaminated food, congenitally, or via blood transfusion or organ transplantation. The acute phase of *T. cruzi* infection is generally controlled by the emerging immune response and is mild or asymptomatic and thus often undetected. However, the vast majority of infected individuals fail to clear the infection and thus remain chronically infected; 30-40% of these will eventually develop life-threatening heart or gastrointestinal disease. Chronic Chagas remains an incurable disease that causes long term severe disability or death in approximately one-third of

infected individuals. In addition, disability caused by chronic Chagas disease has a great social and economic impact, including unemployment and decreased earning ability. In Brazil alone, losses of over US \$1.3 billion in wages and industrial productivity were due to workers with Chagas disease. In addition to the loss in productivity, the medical costs to treat infected individuals who develop severe cardiac or chronic digestive problems are high.

[0009] It has long been established that *T. cruzi* can infect dogs, particularly those who are housed outdoors in the southern US, Central, and South America. A recent study in Texas suggested that shelter dogs serve as a good sentinel for all dogs, and found that ~9% of shelter dogs evaluated across Texas harbored *T. cruzi*. In Texas, *T. cruzi* infection in dogs is considered a “notifiable condition” – any dog found to be harboring the parasite must be reported to the Texas Department of State Health Services. As there is no approved treatment for Chagas disease in dogs, animals may be euthanized.

[0010] Novel chemical entities with novel mechanisms of action are urgently needed to combat these diseases.

Unless otherwise specified, aliphatic groups contain 1-6 aliphatic carbon atoms. In some embodiments, aliphatic groups contain 1-5 aliphatic carbon atoms. In some embodiments, aliphatic groups contain 1-4 aliphatic carbon atoms. In some embodiments, aliphatic groups contain 1-3 aliphatic carbon atoms, and in yet other embodiments, aliphatic groups contain 1-2 aliphatic carbon atoms. In some embodiments, “cycloaliphatic” (or “carbocyclyl” or “cycloalkyl”) refers to a monocyclic C₃-C₇ hydrocarbon that is completely saturated or that contains one or more units of unsaturation, but which is not aromatic, that has a single point of attachment to the rest of the molecule. Suitable substituents include those described below for a substituted aliphatic group.

[0021] The term “halogen” means F, Cl, Br, or I.

[0022] The term “aryl” used alone or as part of a larger moiety as in “aralkyl,” “aralkoxy,” or “aryloxyalkyl,” refers to monocyclic and bicyclic ring systems having a total of five to 10 ring members, wherein at least one ring in the system is aromatic and wherein each ring in the system contains three to seven ring members. The term “aryl” may be used interchangeably with the term “aryl ring”. In some embodiments, an 8-10 membered bicyclic aryl group is an optionally substituted naphthyl ring. In certain embodiments of the present invention, “aryl” refers to an aromatic ring system which includes, but not limited to, phenyl, biphenyl, naphthyl, anthracyl and the like, which may bear one or more substituents. Also included within the scope of the term “aryl,” as it is used herein, is a group in which an aromatic ring is fused to one or more non-aromatic rings, such as indanyl, phthalimidyl, naphthimidyl, phenanthridinyl, or tetrahydronaphthyl, and the like.

[0023] The terms “heteroaryl” and “heteroar-,” used alone or as part of a larger moiety, e.g., “heteroaralkyl,” or “heteroaralkoxy,” refer to groups having 5 to 10 ring atoms, preferably 5, 6, or 9 ring atoms; having 6, 10, or 14 π electrons shared in a cyclic array; and having, in addition to carbon atoms, from one to five heteroatoms. [0027] As described herein, compounds of the invention may, when specified, contain “optionally substituted” moieties. In general, the term “substituted,” whether preceded by the term “optionally” or not, means that one or more hydrogens of the designated moiety are replaced with a suitable substituent. Unless otherwise indicated, an “optionally substituted” group may have a suitable substituent at each substitutable position of the group, and when more than one position in any given structure may be substituted with more than one substituent selected from a specified group, the substituent may be either the same or different at every position. Combinations of substituents envisioned by this invention are preferably those that

result in the formation of stable or chemically feasible compounds. The term “stable,” as used herein, refers to compounds that are not substantially altered when subjected to conditions to allow for their production, detection, and, in certain embodiments, their recovery, purification, and use for one or more of the purposes disclosed herein.

The term “pharmaceutically acceptable salt” is understood in the context of the provided boron-containing compounds to comprise chemical species resulting from the addition of two or more distinct molecules to form a single chemical entity, including Lewis adducts and hydrates thereof.

[0036] In certain embodiments, the neutral forms of the compounds are regenerated by contacting the salt with a base or acid and isolating the parent compound in the conventional manner. In some embodiments, the parent form of the compound differs from the various salt forms in certain physical properties, such as solubility in polar solvents.

[0037] In some embodiments, a pharmaceutically acceptable salt comprises a compound of formula **I** and arginine. In some embodiments, a pharmaceutically acceptable salt comprises a compound of formula **II** and arginine. In some embodiments, a pharmaceutically acceptable salt comprises a compound of formula **III** (e.g., compound I-84) and arginine. In some embodiments, a pharmaceutically acceptable salt comprises a compound of formula **III** (e.g., compound I-84), arginine, and water. In some embodiments, a pharmaceutically acceptable salt may be hydrated. In some embodiments, a pharmaceutically acceptable salt may be a monohydrate. In some embodiments, a pharmaceutically acceptable salt may be anhydrous.

[0038] Unless otherwise stated, structures depicted herein are also meant to include all isomeric (e.g., enantiomeric, diastereomeric, and geometric (or conformational)) forms of the structure; for example, the R and S configurations for each asymmetric center, Z and E double bond isomers, and Z and E conformational isomers. Therefore, single stereochemical isomers as well as enantiomeric, diastereomeric, and geometric (or conformational) mixtures of the present compounds are within the scope of the invention. Unless otherwise stated, all tautomeric forms of the compounds of the invention are within the scope of the invention. Additionally, unless otherwise stated, structures depicted herein are also meant to include compounds that differ only in the presence of one or more isotopically enriched atoms. For example, compounds having the present structures including the replacement of hydrogen by deuterium or tritium, or the replacement of a carbon by a ^{13}C - or ^{14}C -enriched carbon are within the scope of this invention. Such compounds are useful, for example, as analytical tools, as probes in biological assays, or as therapeutic agents in accordance with the present invention.

[0039] The symbol “~”, except when used as a bond to depict unknown or mixed stereochemistry, denotes the point of attachment of a chemical moiety to the remainder of a molecule or chemical formula.

Pharmaceutical Compositions

[0087] In another aspect, the present invention provides pharmaceutical compositions comprising a compound of formula **I** or a compound of formula **I** in combination with a pharmaceutically acceptable excipient (e.g., carrier).

[0088] The pharmaceutical compositions include optical isomers, diastereomers, or pharmaceutically acceptable salts of the inhibitors disclosed herein. The compound of formula **I** included in the pharmaceutical composition may be covalently attached to a carrier moiety, as described above. Alternatively, the compound of formula **I** included in the pharmaceutical composition is not covalently linked to a carrier moiety.

[0089] A “pharmaceutically acceptable carrier,” as used herein refers to pharmaceutical excipients, for example, pharmaceutically, physiologically, acceptable organic or inorganic carrier substances suitable for enteral or parenteral application that do not deleteriously react with the active agent. Suitable pharmaceutically acceptable carriers include water, salt solutions (such as Ringer's solution), alcohols, oils, gelatins, and carbohydrates such as lactose, amylose or starch, fatty acid esters, hydroxymethylcellulose, and polyvinyl pyrrolidone. Such preparations can be sterilized and, if desired, mixed with auxiliary agents such as lubricants, preservatives, stabilizers, wetting agents, emulsifiers, salts for influencing osmotic pressure, buffers, coloring, and/or aromatic substances and the like that do not deleteriously react with the compounds of the invention.

[0090] The compounds of the invention can be administered alone or can be coadministered to the subject. Coadministration is meant to include simultaneous or sequential administration of the compounds individually or in combination (more than one compound). The preparations can

also be combined, when desired, with other active substances (e.g. to reduce metabolic degradation).

Combinations

[0091] The compounds of the invention may also be used in combination with additional therapeutic agents. The invention thus provides, in a further aspect, a combination comprising a compound described herein or a pharmaceutically acceptable salt thereof together with at least one additional therapeutic agent. In an exemplary embodiment, an additional therapeutic agent is a compound of the invention. In an exemplary embodiment, an additional therapeutic agent includes a boron atom.

[0092] When a compound of the invention is used in combination with a second therapeutic agent active against the same disease state, the dose of each compound may differ from that when the compound is used alone. Appropriate doses will be readily appreciated by those skilled in the art. It will be appreciated that the amount of a compound of the invention required for use in treatment will vary with the nature of the condition being treated and the age and the condition of the patient and will be ultimately at the discretion of the attendant physician or veterinarian.

Formulations

[0093] Compounds of the present invention can be prepared and administered in a wide variety of oral, parenteral, and topical dosage forms. Thus, the compounds of the present invention can be administered by injection (e.g. intravenously, intramuscularly, intracutaneously, subcutaneously, intraduodenally, or intraperitoneally). Also, the compounds described herein can be administered by inhalation, for example, intranasally. Additionally, the compounds of the present invention can be administered transdermally. It is also envisioned that multiple routes of administration (e.g., intramuscular, oral, transdermal) can be used to administer the compounds of the invention. Accordingly, the present invention also provides pharmaceutical compositions comprising a pharmaceutically acceptable carrier or excipient and one or more compounds of the invention.

[0094] For preparing pharmaceutical compositions from the compounds of the present invention, pharmaceutically acceptable carriers can be either solid or liquid. Solid form

preparations include powders, tablets, pills, capsules, cachets, suppositories, and dispersible granules. A solid carrier can be one or more substance that may also act as diluents, flavoring agents, binders, preservatives, tablet disintegrating agents, or an encapsulating material.

[0095] In powders, the carrier is a finely divided solid in a mixture with the finely divided active component. In tablets, the active component is mixed with the carrier having the necessary binding properties in suitable proportions and compacted in the shape and size desired.

[0096] The powders and tablets preferably contain from 5% to 70% of the active compound. Suitable carriers are magnesium carbonate, magnesium stearate, talc, sugar, lactose, pectin, dextrin, starch, gelatin, tragacanth, methylcellulose, sodium carboxymethylcellulose, a low melting wax, cocoa butter, and the like. The term "preparation" is intended to include the formulation of the active compound with encapsulating material as a carrier providing a capsule in which the active component with or without other carriers, is surrounded by a carrier, which is thus in association with it. Similarly, cachets and lozenges are included. Tablets, powders, capsules, pills, cachets, and lozenges can be used as solid dosage forms suitable for oral administration.

[0097] For preparing suppositories, a low melting wax, such as a mixture of fatty acid glycerides or cocoa butter, is first melted and the active component is dispersed homogeneously therein, as by stirring. The molten homogeneous mixture is then poured into convenient sized molds, allowed to cool, and thereby to solidify.

[0098] Liquid form preparations include solutions, suspensions, and emulsions, for example, water or water/propylene glycol solutions. For parenteral injection, liquid preparations can be formulated in solution in aqueous polyethylene glycol solution.

[0099] When parenteral application is needed or desired, particularly suitable admixtures for the compounds of the invention are injectable, sterile solutions, preferably oily or aqueous solutions, as well as suspensions, emulsions, or implants, including suppositories. In some embodiments, suitable carriers for parenteral administration will be selected for human administration. In some embodiments, suitable carriers for parenteral administration will be selected for veterinary administration. In particular, carriers for parenteral administration include aqueous solutions of dextrose, saline, pure water, ethanol, glycerol, glycerol formal, polyethylene glycol, propylene glycol, peanut oil, sesame oil, polyoxyethylene-block polymers, pyrrolidine, N-methyl pyrrolidone, and the like. Ampoules are convenient unit dosages. The

compounds of the invention can also be incorporated into liposomes or administered via transdermal pumps or patches. Pharmaceutical admixtures suitable for use in the present invention include those described, for example, in Pharmaceutical Sciences (17th Ed., Mack Pub. Co., Easton, PA) and WO 96/05309, the teachings of both of which are hereby incorporated by reference.

[0100] Aqueous solutions suitable for oral use can be prepared by dissolving the active component in water and adding suitable colorants, flavors, stabilizers, and thickening agents as desired. Aqueous suspensions suitable for oral use can be made by dispersing the finely divided active component in water with viscous material, such as natural or synthetic gums, resins, methylcellulose, sodium carboxymethylcellulose, and other well-known suspending agents.

[0101] Also included are solid form preparations that are intended to be converted, shortly before use, to liquid form preparations for oral administration. Such liquid forms include solutions, suspensions, and emulsions. These preparations may contain, in addition to the active component, colorants, flavors, stabilizers, buffers, artificial and natural sweeteners, dispersants, thickeners, solubilizing agents, and the like.

[0102] The pharmaceutical preparation is preferably in unit dosage form. In such form the preparation is subdivided into unit doses containing appropriate quantities of the active component. The unit dosage form can be a packaged preparation, the package containing discrete quantities of preparation, such as packeted tablets, capsules, and powders in vials or ampoules. Also, the unit dosage form can be a capsule, tablet, cachet, or lozenge itself, or it can be the appropriate number of any of these in packaged form.

[0103] The quantity of active component in a unit dose preparation may be varied or adjusted from 0.1 mg to 10000 mg, more typically 1.0 mg to 1000 mg, most typically 10 mg to 500 mg, according to the particular application and the potency of the active component. The composition can, if desired, also contain other compatible therapeutic agents.

[0104] Some compounds may have limited solubility in water and therefore may require a surfactant or other appropriate co-solvent in the composition. Such co-solvents include: Polysorbate 20, 60, and 80; Pluronic F-68, F-84, and P-103; cyclodextrin; and polyoxyl 35 castor oil. Such co-solvents are typically employed at a level between about 0.01 % and about 2% by weight.

[0105] Viscosity greater than that of simple aqueous solutions may be desirable to decrease variability in dispensing the formulations, to decrease physical separation of components of a suspension or emulsion of formulation, and/or otherwise to improve the formulation. Such viscosity building agents include, for example, polyvinyl alcohol, polyvinyl pyrrolidone, methyl cellulose, hydroxy propyl methylcellulose, hydroxyethyl cellulose, carboxymethyl cellulose, hydroxy propyl cellulose, chondroitin sulfate and salts thereof, hyaluronic acid and salts thereof, and combinations of the foregoing. Such agents are typically employed at a level between about 0.01% and about 2% by weight.

[0106] The compositions of the present invention may additionally include components to provide sustained release and/or comfort. Such components include high molecular weight, anionic mucomimetic polymers, gelling polysaccharides, and finely-divided drug carrier substrates. These components are discussed in greater detail in U.S. Pat. Nos. 4,911,920; 5,403,841; 5,212,162; and 4,861,760. The entire contents of these patents are incorporated herein by reference in their entirety for all purposes.

[0107] For administration to non-human animals, the composition containing the therapeutic compound may be added to the animal's feed or drinking water. Also, it will be convenient to formulate animal feed and drinking water products so that the animal takes in an appropriate quantity of the compound in its diet. It will further be convenient to present the compound in a composition as a premix for addition to the feed or drinking water. The composition can also be formulated as a food or drink supplement for humans.

Effective Dosage

[0108] Pharmaceutical compositions provided by the present invention include compositions wherein the active ingredient is contained in a therapeutically effective amount, i.e., in an amount effective to achieve its intended purpose. The actual amount effective for a particular application will depend, *inter alia*, on the condition being treated. For example, when administered in methods to a parasitic infection, such compositions will contain an amount of active ingredient effective to achieve the desired result.

[0109] The dosage and frequency (single or multiple doses) of compound administered can vary depending upon a variety of factors, including route of administration; size, age, sex, health, body weight, body mass index, and diet of the recipient; nature and extent of symptoms of the

disease being treated; presence of other diseases or other health-related problems; kind of concurrent treatment; and complications from any disease or treatment regimen. Other therapeutic regimens or agents can be used in conjunction with the methods and compounds of the invention.

[0110] For any compound described herein, the therapeutically effective amount can be initially determined from cell culture assays. Target concentrations will be those concentrations of active compound(s) that are capable of killing parasites and/or controlling their growth or reproduction as measured, for example, using the methods described.

[0111] Therapeutically effective amounts for use in humans may be determined from animal models. For example, a dose for humans can be formulated to achieve a concentration that has been found to be effective in animals. The dosage in humans can be adjusted by monitoring kinase inhibition and adjusting the dosage upwards or downwards, as described above. Therapeutically effective amounts for use in animals (e.g., cattle) may be determined from animal models (e.g., mouse models).

[0112] Dosages may be varied depending upon the requirements of the patient and the compound being employed. The dose administered to a patient, in the context of the present invention, should be sufficient to effect a beneficial therapeutic response in the patient over time. The size of the dose also will be determined by the existence, nature, and extent of any adverse side effects. Generally, treatment is initiated with smaller dosages, which are less than the optimum dose of the compound. Step 1

[0115] To a solution of ethyl acetoacetate (1.2 equiv.) in a mixture of DMSO: H₂O (9:1, 10 vol) was added piperidine (0.2 equiv.) and was stirred at RT for 30 min. Then compound **1-1** (5.0 g, 1.0 equiv.) was added to the reaction mixture and stirring was continued at RT for 24 h. The progress of the reaction was monitored by TLC. TLC indicated formation a polar spot with completed consumption of starting material. After work-up and column purification 1.9 g of compound **1-2** was isolated.

Step 2

[0116] To a stirred solution of compound **1-2** (1.9 g) in THF:H₂O (3:1, 10 vol) was added LiOH•H₂O (3 equiv.) at RT. The reaction mixture was stirred at RT for 16 h. The progress of the reaction was monitored by TLC. TLC indicated formation of a polar spot with completed consumption of starting material. The solvent was removed under reduced pressure to get the residue, which was acidified with 2N HCl at 0 °C until pH 3.0 to get solid compound. Example 105. *Trypanosoma brucei brucei* High-Throughput Screening Assay Procedure

[0283] All experiments were conducted with the bloodstream-form trypanosome *T. brucei brucei* 427 strain obtained from Seattle Biomedical Research Institute (Seattle, WA). Parasites were cultured in T-25 vented cap flasks and kept in humidified incubators at 37 °C and 5% CO $_2$. The parasite culture media was complete HMI- 9 medium containing 10% FBS, 10% Serum Plus medium and penicillin/streptomycin. To ensure log growth phase, trypanosomes were sub-cultured at appropriate dilutions every 2-3 days. Approximately 50 microliters of log phase

cultures were diluted 1:10 in HMI-9 and 10 μ L of the diluted culture was removed and counted using a hemocytometer to determine parasite concentration. Parasites were diluted by addition of an appropriate volume of HMI-9 to achieve a final parasite concentration of 2×10^5 /mL. Compounds of the invention to be tested were serially diluted in DMSO and 0.5 μ L added to 49.5 μ L HMI-9 in triplicate 96-well plates using a Biomek NX liquid handler. Parasites from the diluted stock were added to each well (50 μ L) using a Multidrop 384 dispenser to give a final concentration of 1.0×10^5 /ml parasites in 0.4% for DMSO. Trypanosomes were incubated with compounds for 72 hrs at 37 °C with 5% CO₂. Resazurin (20 μ L of 12.5 mg/ml stock) from Sigma-Aldrich was added to each well and plates were incubated for an additional 2-4 hrs. Assay plates were read using an EnVision plate reader at an excitation wavelength of 544 nm and emission of 590 nm. Triplicate data points were averaged to generate sigmoidal dose response curve and determine IC₅₀ values using XLfit curve fitting software from IDBS (Guildford, UK). Data are shown below in Table 1, where compounds having an activity designated as “A” provided an IC₅₀ < 0.075 μ M; compounds having an activity designated as “B” provided an IC₅₀ of 0.075 – 0.150 μ M; and compounds having an activity designated as “C” provided an IC₅₀ of 0.151 – 10.0 μ M.

Example 106. In vitro Alamar Blue 72 h drug sensitivity assay for *T. congolense*

[0284] Compounds were tested in vitro for chemotherapeutic potency against the IL3000 *T. congolense* (drug sensitive) strain, using the Alamar Blue assay with several modifications. Test compounds were prepared as 10 mg/mL DMSO stocks for each assay run. Compounds were assayed in at least three separate, independent test runs and an 11-point dilution curve was used to determine the IC₅₀ values. Bloodstream form trypanosomes were supported in HMI media containing 20 % bovine serum and were incubated with test compounds for 69 h at 34 °C in a humidified atmosphere containing 5% CO₂. Thereafter, 10 μ L of Resazurin dye (12.5 mg in 100 mL of phosphate buffered saline, Sigma-Aldrich, Buchs, Switzerland) were added for an additional 3 h. Plates were then read using a fluorescent plate reader (Spectramax, Gemini XS, Bucher Biotec, Basel, Switzerland) using an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Data points were averaged to generate sigmoidal dose-response curves and IC₅₀ values were determined using Softmax Pro 5.2 software. Data are shown below in

Table 1, where compounds having an activity designated as “A” provided an $IC_{50} < 0.1 \mu M$; compounds having an activity designated as “B” provided an IC_{50} of $0.1 - 0.3 \mu M$; compounds having an activity designated as “C” provided an IC_{50} of $0.31-100 \mu M$; compounds having an activity designated as “D” provided an inhibition of greater than or equal to 75% at a concentration of $1.0 \mu M$; compounds having an activity designated as “E” provided an inhibition of less than 75% at a concentration of $1.0 \mu M$.

Example 107. Assay for *Leishmania major* intracellular amastigote assay in RAW 264.7 macrophages

[0285] The intracellular amastigote assay is a microtiter plate drug sensitivity assay that uses the activity of luciferase as a measure of proliferation of luciferase-expressing *L. major* parasites developing intracellularly inside RAW 264.7 macrophages in the presence of antileishmanial drugs or experimental compounds. (Buckner, F.S., and A.J. Wilson. *Am J Trop Med Hyg*, **2005**, 72(5): 600-605.) As the activity of luciferase and its associated luminescence after addition of the substrate, luciferin, is relative to parasite growth, a test compound that inhibits the growth of the parasite will result in a lower luminescence. The luciferase-expressing *L. major* parasite used in this assay is genetically modified by adding the luciferase coding region to the pLEXSY-hyg2 vector (Jena Biosciences). The luciferase expression construct was created by digesting the luciferase coding region (1.66kbp) of pGL3-Basic (Promega) by using two restriction enzymes, NcoI/EagI, followed by electrophoretic separation of the luciferase coding region on a 1% agarose gel. The luciferase coding region was then ligated into pLEXSY-hyg2 vector (Jena Biosciences) which had previously been digested with NcoI/NotI. The vector was linearized with SwaI and subsequently gel purified prior to transfection into *L. major* parasites. Transfections were carried out by electroporation at 480V, 13 Ω , and 500 μF (0.4 mL of 1×10^8 parasites/mL, and 0.1 mL of 10 μg DNA). Selection for transfectants was then carried out using hygromycin B (100 μg /mL). RAW 264.7 macrophages were cultured in DMEM media (ATCC Cat# 30-2002) supplemented with heat-inactivated 10% FBS (Invitrogen Cat# 10438-034). To begin the assay, macrophages were harvested from culture by removing all spent media, adding in 10 mL fresh media, scraping cells, and counted using Trypan Blue. The cells were resuspended in DMEM/10% HIFBS media at 2.0×10^5 cells/mL, and then dispensed in a volume of 50 μL to yield a final concentration of 10,000 macrophages/well in 384 well tissue-

culture treated sterile white plates (Nunc Cat# 12-565-343) using a Tecan EVO Freedom robotics system. The plates were then incubated at 37 °C overnight in 5% CO₂ atmosphere for 24 hours. After overnight incubation, the media was removed from each well using the Tecan EVO Freedom robot, and L. major promastigotes were added to each well and allowed to invade the RAW macrophages. Promastigotes were cultured in Schneider's medium (Invitrogen Cat# 11720-067) supplemented with 20% heat inactivated FBS. Metacyclic stage promastigotes provide the best invasion for this assay, and cultures should be grown to increase the percentage of metacyclic promastigotes for best results. Promastigotes were harvested from culture, counted, suspended at 2×10^6 promastigotes/mL in DMEM/HIFBS media, and 100,000 promastigotes were dispensed per well in a volume of 50 μ L. After overnight incubation, the media was removed from each well using the Tecan Freedom EVO robot, and each well was subsequently washed three times with 40 μ L of fresh DMEM/HIFBS medium to remove all extracellular promastigotes. After the third wash, 69.2 μ L of DMEM/HIFBS medium was added to each well using the Tecan EVO Freedom robot. Drug plates were prepared with the Tecan EVO Freedom using sterile 96 well plates containing twelve duplicate two-fold serial dilutions of each test compound suspended in DMSO. 7.8 μ L of diluted test compound was added to the 69.2 μ L of media present in each well providing a 10 fold final dilution of compound. The final concentration range tested was 0.5 to 10,000 ng/ml for all assays. The plates were next incubated at 37°C and 5% CO₂ for 96 hours. After 96 hours of incubation, 7.5 μ L of a luciferin solution (Caliper Life Science) diluted to 150 μ g/mL was added to each well, and the plates were incubated for 30 minutes at 37 °C, in the dark. Each plate was read using a Infinite M200 plate reader. The 50% inhibitory concentrations (IC₅₀s) were then generated for each dose response test using GraphPad Prism (GraphPad Software Inc., San Diego, CA) using the nonlinear regression (sigmoidal dose-response/variable slope) equation. Data are shown below in Table 1, where compounds having an activity designated as "A" provided an IC₅₀ $\leq$ 1.0 μ M; compounds having an activity designated as "B" provided an IC₅₀ of 1.1-9.9 μ M; and compounds having an activity designated as "C" provided an IC₅₀ of 10-50 μ M.

Example 108. *Leishmania major* promastigote growth inhibition assay

[0286] The promastigote assay is a microtiter plate drug sensitivity prescreen assay used to determine antileishmanial activity of candidate drugs against promastigote forms of *L. major*. (Sharlow et al., PLOS Neglected Tropical Diseases, **2009**, e311.) Alamar Blue, or resazurin, is a non-fluorescent indicator dye that is converted to bright red–fluorescent resorufin via the activity of mitochondrial reductases. As the activity of mitochondrial reductases is reduced in cells that are dead or dying, and the intensity of the fluorescence is relative to cell number, a test compound that kills or inhibits growth of a particular target cell, such as *L. major*, will result in a lower production of fluorescent signal. Pre-dosed microtiter drug plates for use in the promastigote drug prescreen assay were produced using sterile 384-well black optical bottom tissue culture plates (Nunc Cat#12-565-344). Candidate drugs were diluted in dimethyl sulfoxide in four 96-well plates to either 10,000 ng/ml or 1,000 ng/ml, and 4.25 μ L of diluted drug was subsequently dispensed into each well of a 384-well plate. Duplicate 384 well plates were made at each test concentration (10,000ng/mL and 1,000ng/mL) and amphotericin B was used as a batch control. The Tecan EVO Freedom liquid handling system (Tecan US, Inc., Durham, NC) was used to produce all drug assay plates and conduct all pipetting operations for this assay. *L. major* parasites were cultured in Schneider's medium (Lonza Cat# 04-351Q) supplemented with 20% heat inactivated FBS (Invitrogen Cat# 16140-089). Promastigotes in early log growth phase were harvested from culture, counted, suspended at 1.32×10^5 cells/mL and 5,000 promastigotes were dispensed into each well of the 384 well plate in a volume of 38.8 μ L. The 384 well plates were subsequently incubated at 28 °C for 44 hours. 8.4 μ L of Alamar Blue (Promega, Cat # G8081) was added to each well, the plates were subsequently incubated at 28 °C and 5% CO₂ for 4 hours and then examined for the relative fluorescence units (RFU) per well using the Tecan Genios Plus (Tecan US, Inc., Durham, NC) with excitation set at 560 nm and emission set at 590 nm. The relative fluorescence from each well was used to determine the percent growth inhibition of each candidate compound tested. Compounds with 50% or greater inhibition of growth were selected for further analysis to determine IC₅₀ values. Data are shown below in Table 1, where compounds having an activity designated as “A” provided an IC₅₀ < 0.6 μ M; compounds having an activity designated as “B” provided an IC₅₀ of 0.6-2.5 μ M; and compounds having an activity designated as “C” provided an IC₅₀ of 2.51-20 μ M.

Example 109. Ex vivo Alamar Blue 48 h drug sensitivity assay for *T. vivax*

[0287] Compounds were tested ex vivo for chemotherapeutic potency against the STIB719 / ILRAD560 *T. vivax* (drug sensitive) strain, using the Alamar Blue assay with several modifications. Test compounds were prepared as 10 mg/mL DMSO stocks for each assay run. Compounds were assayed in at least three separate, independent test runs and an 11-point dilution curve was used to determine the IC₅₀ values. Bloodstream form trypanosomes were propagated and harvested from a highly parasitemic mouse (via cardiac puncture) and were incubated with test compounds for 45 hrs at 37 °C in a humidified atmosphere containing 5% CO₂, supported in HMI media containing 20% bovine serum. Thereafter, 10 µL of Resazurin dye (12.5 mg in 100 mL of phosphate buffered saline, Sigma-Aldrich, Buchs, Switzerland) were added for an additional 3 hrs. Plates were then read using a fluorescent plate reader (Spectramax, Gemini XS, Bucher Biotec, Basel, Switzerland) using an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Data points were averaged to generate sigmoidal dose-response curves and IC₅₀ values were determined using Softmax Pro 5.2 software. Data are shown below in Table 1, where compounds having an activity designated as “A” provided an IC₅₀ ≤ 0.2 µM; compounds having an activity designated as “B” provided an IC₅₀ of 0.201-0.5 µM; and compounds having an activity designated as “C” provided an IC₅₀ of 0.51-10 µM.

Example 110. *T. brucei rhodesiense* STIB 900 Growth Inhibition Assay

[0288] The parasite strain used in this assay was isolated in 1982 from a human patient in Tanzania and after several mouse passages cloned and adapted to axenic culture conditions. ((a) Baltz, T., D. Baltz, C. Giroud, and J. Crockett. EMBO Journal, 1985, 4:1273-1277. (b) Thuita, J. K., S. M. Karanja, T. Wenzler, R. E. Mdachi, J. M. Ngotho, J. M. Kagira, R. Tidwell, and R. Brun. Minimum Essential Medium (50 µl) supplemented with 25 mM HEPES, 1 g/l additional glucose, 1% MEM non-essential amino acids (100x), 0.2 mM 2-mercaptoethanol, 1mM Na-pyruvate and 15% heat inactivated horse serum was added to each well of a 96-well microtiter plate. Serial drug dilutions of seven 3-fold dilution steps covering a range from 90 to 0.123 µg/ml were prepared. Then 10⁴ bloodstream forms of *T. b. rhodesiense* STIB 900 in 50 µl was added to each well and the plate incubated at 37 °C under a 5 % CO₂ atmosphere for 72 h. 10 µl Alamar Blue (resazurin, 12.5 mg in 100 ml double-distilled water)

was then added to each well and incubation continued for a further 2–4 h. (Räz, B., M. Iten, Y. Grether-Buhler, R. Kaminsky, and R. Brun. *Acta Trop* 1997, 68:139-47.) Then the plates were read with a Spectramax Gemini XS microplate fluorometer (Molecular Devices Cooperation, Sunnyvale, CA, USA) using an excitation wave length of 536 nm and an emission wave length of 588 nm. Data were analyzed using the microplate reader software Softmax Pro (Molecular Devices Cooperation, Sunnyvale, CA, USA). Data are shown below in Table 1, where compounds having an activity designated as “A” provided an $IC_{50} < 0.1 \mu M$; compounds having an activity designated as “B” provided an IC_{50} of 0.1-0.3 μM ; and compounds having an activity designated as “C” provided an IC_{50} of 0.31-10 μM .

Example 111. *Leishmania infantum* intracellular amastigote assay in mouse macrophages

[0289] *L. infantum* MHOM/MA(BE)/67 amastigotes were collected from the spleen of an infected donor hamster and used to infect primary peritoneal mouse macrophages. (Kaiser, M., Maes, L., Tadoori, L.P., Spangenberg, T., Ioset, J.-R. *J. Biomol. Screen.* **2015** 20(5), 634-35.) To determine in vitro antileishmanial activity, 3×10^4 macrophages were seeded in each well of a 96-well plate. Culture medium was RPMI-1640 supplemented with L-glutamine (20 mM), 16.5 mM sodium hydrogen carbonate, and 10% fetal calf serum (FCS). After 2 d of outgrowth, 5×10^5 amastigotes/well were added and incubated for 2 h at 37 °C. Prediluted samples to be tested were subsequently added, and the plates were further incubated for 5 d at 37 °C and 5% CO₂. Total parasite burdens in the well were microscopically assessed after Giemsa staining and expressed as a percentage of the total burden in the blank controls without compound. In treated wells with high amastigote burdens, an overall estimate of the total burden per well was made without discrimination between the number of infected macrophages and the number of amastigotes per infected cell. In treated wells with low burdens, exact counting was performed. The 50% inhibitory concentrations (IC_{50} s) were then generated for each dose response test using GraphPad Prism (GraphPad Software Inc., San Diego, CA) using the nonlinear regression (sigmoidal dose-response/variable slope) equation. Data are shown below in Table 1, where compounds having an activity designated as “A” provided an $IC_{50} < 3.0 \mu M$; compounds having an activity designated as “B” provided an IC_{50} of 3.0-19.9 μM ; and compounds having an activity designated as “C” provided an IC_{50} of 20-100 μM .

Example 112. *In vitro* IC₅₀ measurement of *T. cruzi* amastigote killing using TdTomato-modified *T. cruzi* (CL strain):

[0290] The *T. cruzi* parasites used in this assay were genetically modified to express TdTomato fluorescent protein. Vero cells (African green monkey kidney epithelial cells) were harvested from continuous cultures using trypsin and added to the inner 60 wells of 96-well Greiner Bio One plates (plate catalog # 655090) at 200 μ L/well of 2.5×10^6 cells/mL. Cells were allowed to adhere for 1h before infection with *T. cruzi*. *T. cruzi* for infection were harvested from previously-infected Vero cells, washed, pelleted and resuspended at 5×10^6 /mL. 50 μ L of parasites were added to each well containing Vero cells. Compounds were prepared from 5 mM stock concentrations in DMSO to final concentrations in wells ranging from 5 μ M to 5 nM. Wells were provided for negative controls, lacking compounds. Plates were placed into a 37 °C incubator for 20 min, then a “Day 0” reading was taken on a Synergy H4 plate reader to record initial fluorescence levels, at 544 (excitation) and 612 nm (emission). 96-well plates were placed in Tupperware containers with wet paper towels and incubated at 37 °C incubator for 72 h. After 72 h plates were reread (Day 3 reading) and data analyzed using Excel and/or Graphpad software. Day 0 fluorescence was subtracted from Day 3 to remove input parasite fluorescence. Growth curves are generated and 50% and 90% inhibitory concentrations are determined by nonlinear regression analysis. Data are shown below in Table 1, where compounds having an activity designated as “A” provided an IC₅₀ < 0.6 μ M; compounds having an activity designated as “B” provided an IC₅₀ of 0.6-1.0 μ M; and compounds having an activity designated as “C” provided an IC₅₀ of 1.1-10 μ M.

After 24 h the medium was removed and replaced by 100 μ L per well containing 5×10^3 trypomastigote forms of *T. cruzi* Tulahuen strain C2C4 containing the β -galactosidase (Lac Z) gene (Buckner, et al., *Antimicrobial Agents and Chemotherapy*, 40: 2592-2597 (1996)). After 48 h the medium was removed from the wells and replaced by 100 μ L fresh medium with or without a serial drug

dilution of the seven 3-fold dilution steps covering a range from 90 to 0.123 $\mu\text{g/mL}$. After 96 h of incubation the plates were inspected under an inverted microscope to assure growth of the controls and sterility. The substrate (50 μL) chlorophenol red- β -D-galactopyranoside (CPRG, Roche Diagnostics, Ltd) in 0.25% Nonidet P-40/PBS was added to all wells and a color reaction developed within 2 – 6 h which was read photometrically at 540 nm. Data were transferred into the graphic program Softmax Pro (Molecular Devices), which calculated IC_{50} values. Data are shown below in Table 1, where compounds having an activity designated as “A” provided an $\text{IC}_{50} < 0.06 \mu\text{M}$; compounds having an activity designated as “B” provided an IC_{50} of 0.06-0.10 μM ; and compounds having an activity designated as “C” provided an IC_{50} of 0.11-1.0 μM .
