(54) Title: STEERABLE ULTRASOUND CATHETER

(57) Abstract: Ultrasound catheter devices and methods provide enhanced disruption of blood vessel obstructions. Ultrasound catheter devices generally include an elongate flexible catheter body with one or more lumens, an ultrasound transmission member extending longitudinally through the catheter body lumen and a distal head coupled with the transmission member and positioned adjacent the distal end of the catheter body for disrupting occlusions. Improved features of ultrasound catheters include catheter bodies and ultrasound transmission members with increasing distal flexibility, guidewire tubes allowing contact between a guidewire and an ultrasound transmission member, distal heads with improved guidewire lumens, and torquable proximal housings for enhancing disruption of blood vessel occlusions.

STEERABLE ULTRASOUND CATHETER

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to U.S. Patent Application Serial No. 10/722,209 (Attorney Docket No. 021577-000900US), filed November 24, 2003, the full disclosure of which is hereby incorporated by reference. This application is related to the following pending U.S. Patent Applications, the full disclosures of which are all hereby incorporated by reference: Application Serial No. 10/229,371, filed August 26, 2002, entitled "Ultrasound Catheter for Disrupting Blood Vessel Obstructions," (Attorney Docket No. 21577-000400US); Application Serial No. 10/345078, filed January 14, 2003, entitled "Ultrasound Catheter and Methods for Making and Using Same," (Attorney Docket No. 21577-000600US); Application Serial No. 10/375,903, filed February 26, 2003, entitled "Ultrasound Catheter Apparatus," (Attorney Docket No. 21577-000700US); and Application Serial No. 10/410617, filed April 8, 2003, entitled "Improved Ultrasound Catheter Devices and Methods."

BACKGROUND OF THE INVENTION

[0002] The present invention relates generally to medical devices and methods. More specifically, the present invention relates to ultrasound catheter devices and methods for treating occlusive intravascular lesions.

[0003] Catheters employing various types of ultrasound transmitting members have been successfully used to ablate or otherwise disrupt obstructions in blood vessels. Specifically, ablation of atherosclerotic plaque or thromboembolic obstructions from peripheral blood vessels such as the femoral arteries has been particularly successful. Various ultrasonic catheter devices have been developed for use in ablating or otherwise removing obstructive material from blood vessels. For example, U.S. Patent Nos. 5,267,954 and 5,380,274, issued to an inventor of the present invention and hereby incorporated by reference, describe ultrasound catheter devices for removing occlusions. Other examples of ultrasonic ablation devices for removing obstructions from blood vessels include those described in U.S. Patent Nos. 3,433,226 (Boyd), 3,823,717 (Pohlman, et al.), 4,808,153 (Parisi), 4,936,281 (Stasz), 3,565,062 (Kuris), 4,924,863 (Sterzer), 4,870,953 (Don Michael, et al), and 4,920,954 (Alliger, et al.), as well as other patent publications W087-05739 (Cooper), W089-06515 (Bernstein, et al.), W090-0130 (Sonic Needle Corp.), EP, EP3 16789 (Don Michael, et al.),

DE3,821,836 (Schubert) and DE2438648 (Pohlman). While many ultrasound catheters have been developed, however, improvements are still being pursued.

[0004] Typically, an ultrasonic catheter system for ablating occlusive material includes three basic components: an ultrasound generator, an ultrasound transducer, and an ultrasound catheter. The generator converts line power into a high frequency current that is delivered to the transducer. The transducer contains piezoelectric crystals which, when excited by the high frequency current, expand and contract at high frequency. These small, high-frequency expansions (relative to an axis of the transducer and the catheter) are amplified by the transducer horn into vibrational energy. The vibrations are then transmitted from the transducer through the ultrasound catheter via an ultrasound transmission member (or wire) running longitudinally through the catheter. The transmission member transmits the vibrational energy to the distal end of the catheter where the energy is used to ablate or otherwise disrupt a vascular obstruction.

[0005] To effectively reach various sites for treatment of intravascular occlusions, ultrasound catheters of the type described above typically have lengths of about 150 cm or longer. To permit the advancement of such ultrasound catheters through small and/or tortuous blood vessels such as the aortic arch, coronary vessels, and peripheral vasculature of the lower extremities, the catheters (and their respective ultrasound transmission wires) must typically be sufficiently small and flexible. Also, due to attenuation of ultrasound energy along the long, thin, ultrasound transmission wire, a sufficient amount of vibrational energy must be applied at the proximal end of the wire to provide a desired amount of energy at the distal end.

[0006] A number of ultrasound catheter devices have been described, for example in Patent Application Serial Nos. Application Serial No. 10/229,371, 10/345078, 10/375,903, and 10/410617, which were previously incorporated by reference. Improvements, however, are always being sought. For example, it continues to be challenging to develop a catheter that is stiff enough to be pushable or "steerable" through vasculature yet flexible enough, at least along part of its length, to navigate small, tortuous blood vessels, such as the coronary arteries or tortuous peripheral vasculature. It is also sometimes difficult to manipulate currently available ultrasound catheter devices, for example to twist or torque the proximal end of the catheter to move the distal end in a way that helps with navigation through the vasculature. Passage of a guidewire through an ultrasound catheter may also be improved

upon, such that the guidewire does not interfere with, and may even enhance, disruption of vascular occlusions.

[0007] Therefore, a need exists for improved ultrasound catheter devices and methods that provide ablation or disruption of vascular occlusions. Ideally, such ultrasound catheters would have enhanced ability to navigate through small, tortuous blood vessels such as the coronary arteries. It would also be advantageous to have catheters that could be easily manipulated by a user. Ideally, such devices would allow for passage of a guidewire without interfering with, and perhaps even enhancing, disruption of vascular occlusions. At least some of these objectives will be met by the present invention.

BRIEF SUMMARY OF THE INVENTION

[0008] Ultrasound catheter devices and methods provide enhanced disruption of blood vessel obstructions. Generally, ultrasound catheters include an elongate flexible catheter body with one or more lumens, an ultrasound transmission member extending longitudinally through the catheter body lumen, and a distal head coupled with the transmission member and positioned adjacent the distal end of the catheter body for disrupting occlusions. Improved features include but are not limited to catheter bodies and ultrasound transmission members with increasing flexibility toward their distal ends, devices that bend concomitantly with one or more bends in a guidewire and/or a blood vessel, a proximal housing coupled with an ultrasound catheter body for enhancing manipulation of the catheter body, a guidewire lumen configured to allow contact between a guidewire and an ultrasound transmission member, distal heads with improved guidewire lumens and the like.

[0009] In one aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels is provided, which can be guided from an access site on a patient's body to a target site adjacent an occlusion. The ultrasound catheter generally includes an elongate flexible catheter body, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. The catheter body has a proximal portion, a distal portion and at least one lumen, the proximal portion being stiffer than the distal portion, and the distal portion being more flexible near the distal end of the catheter body than near the proximal portion of the catheter body. The ultrasound transmission member has a

proximal end and a distal end and is more flexible near its distal end than near its proximal end. Thus, both the distal portion of the catheter body and the ultrasound transmission member are more flexible toward the distal end of the device.

[0010] The increasing flexibility of the catheter body and the ultrasound transmission wire toward the distal end of the catheter device may be achieved by any suitable fabrication method. In some embodiments, for example, the ultrasound transmission wire, catheter body, or both may be tapered, such that their cross-sectional diameters decrease distally. In one embodiment, for example, the cross-sectional diameter of a catheter body may range from between about 0.102 cm and about 0.178 cm along its proximal end to between about 0.076 cm and about 0.127 cm along its distal end, and the cross-sectional diameter of an ultrasound transmission member may range from between about 0.051 cm and about 0.102 cm near its proximal end to between about 0.013 cm and about 0.038 cm near its distal end. Additionally or alternatively, the wall thickness of the catheter body may decrease from proximal to distal. For example, in one embodiment, the wall thickness of a catheter body may measure about 0.007 cm to about 0.020 cm along its proximal portion and about 0.005 cm to about 0.013 cm along its distal portion. In these or other embodiments, various combinations of materials may be used to give the catheter body, transmission wire or both a desired flexibility profile. Providing an ultrasound catheter with a catheter body and ultrasound transmission wire that both increase in flexibility toward the distal end of the device will enhance navigation of the distal end of the device through tortuous blood vessels. In one embodiment, for example, the distal portion of the device will be sufficiently flexible to pass, without kinking, through at least 5 cm length of a blood vessel having at least one bend and an inner diameter of between about 2 mm and about 5 mm. A "tortuous vessel," for the purposes of this application, means having at least one bend or curve, and the bend or curve may have any angle or radius of curvature. In some embodiments, for example, at least one bend in a vessel may have a radius of about 1.0 cm or less. In some instances, of course, a tortuous blood vessel will have multiple bends or curves.

[0011] In another aspect of the invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided along a guidewire from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and

disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect, the catheter body has a proximal portion, a distal portion and at least one lumen, the proximal portion has a larger cross-sectional diameter than the distal portion, the proximal portion is sufficiently stiff to push the distal portion through a blood vessel having at least one bend, and the distal portion is sufficiently flexible to pass through the bend in the blood vessel. The ultrasound transmission member has a proximal end and a distal end, the cross-sectional diameter of the ultrasound transmission member is less near its distal end than near its proximal end, and a distal portion of the ultrasound transmission member is sufficiently flexible to pass through the bend in the blood vessel. Again, in some embodiments the wall of the catheter body may be thinner along the distal portion than along the proximal portion.

[0012] In another aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect, the distal portion of the catheter body is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body, and the ultrasound transmission member is more flexible near its distal end than near its proximal end. Additionally, the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly with at least one bend in a guidewire extended through the at least one lumen.

[0013] By "conforming concomitantly" it is meant that the catheter body and the ultrasound transmission member conform to the at least one bend in the guidewire such that the catheter body, transmission member and guidewire bend at an approximately similar angle. In some embodiments, the distal portion of the catheter body and the ultrasound transmission wire are sufficiently flexible to conform concomitantly to multiple bends in the guidewire. Also in some embodiments, the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly to multiple bends in a blood vessel. In various embodiments, the catheter may be advanced over a guidewire, a guidewire

may be passed through the catheter body, or the catheter body, ultrasound transmission wire and guidewire may be advanced through a blood vessel simultaneously. Thus, in various embodiments, the distal portion of the catheter body, the ultrasound transmission wire and the guidewire may be passed together or sequentially through the multiple bends in the blood vessel while conforming concomitantly to the multiple bends.

[0014] In another aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect, the distal portion of the catheter body has at least one bend, and at least one lumen, the proximal portion of the catheter body is stiffer than the distal portion, and the distal portion is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body. The ultrasound transmission member is more flexible near its distal end than near its proximal end, the ultrasound transmission member conforms to the at least one bend in the distal portion of the catheter body, and the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly to at least one bend in a guidewire.

[0015] In still another aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect, the catheter body includes a guidewire tube disposed within the lumen, and the proximal portion of the body is stiffer than the distal portion. The guidewire tube includes at least one opening within the catheter body

for providing contact between a guidewire extending through the guidewire tube and the ultrasound transmission member.

[0016] Allowing a guidewire to contact the ultrasound transmission member may facilitate passage of the guidewire into or through a vascular occlusion, by allowing a portion of the ultrasound energy transmitted by the transmission member to be transferred to the guidewire. In various embodiments, the guidewire may contact the transmission member near the proximal end of the catheter device, near the distal end, near the middle, or some combination thereof. In some embodiments, the guidewire tube includes two openings within the catheter body, to allow the transmission member to pass through the tube. Any other configuration for allowing contact between a guidewire and the ultrasound transmission member is also contemplated.

[0017] In another aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect, the distal head includes a guidewire aperture in the center of its distal end and a guidewire lumen extending through the distal head. The guidewire lumen, in turn, has a different longitudinal axis than the longitudinal axis of the catheter body.

[0018] Having a guidewire lumen that exits from the center of the distal head is advantageous for advancing the guidewire as well as the catheter device. Angling the guidewire lumen away from the longitudinal axis of the catheter body allows a guidewire and the ultrasound transmission member to pass through a narrower catheter body, thus decreasing the diameter of the catheter device and facilitating passage through tortuous vessels. In some embodiments, the guidewire lumen in the distal head includes a cavity in which a distal end of a guidewire tube of the catheter body is disposed. In some embodiments, the cavity extends through the distal end of the distal head, such that the distal end of the guidewire tube is flush with the distal end of the distal head. In other

embodiments, the cavity extends partially through the distal head, such that the distal end of the guidewire tube is disposed proximal to the distal end of the distal head.

[0019] In another aspect of the present invention, an ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion includes an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, an ultrasound transmission member extending longitudinally through the lumen of the catheter body, a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, and at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy. In this aspect of the invention, the at least one coupling member comprises a housing fixedly coupled with the proximal end of the catheter body such that torque applied to the housing is transmitted along the catheter body to its distal portion.

[0020] In yet another aspect of the invention, a method for disrupting an occlusion in a blood vessel involves: advancing an ultrasound catheter through a blood vessel having at least one bend, the catheter conforming concomitantly to the at least one bend, wherein advancing includes contacting an ultrasound transmission member of the ultrasound catheter with a guidewire at one or more locations within the catheter; positioning a distal end of the ultrasound catheter adjacent an occlusion in the blood vessel; and transmitting ultrasound energy to the ultrasound transmission member to disrupt the occlusion into multiple occlusion fragments, wherein transmitting includes transmitting ultrasound energy to the guidewire. Optionally, the method may further include removing at least some of the occlusion fragments from the blood vessel via the ultrasound catheter. In some embodiments, the ultrasound catheter is advanced along the guidewire. Alternatively, the guidewire may be passed through the catheter, or the catheter and the guidewire may be advanced together through the blood vessel. Positioning may also involve advancing the ultrasound catheter and the guidewire along multiple bends in the blood vessel, wherein a catheter body of the catheter, the ultrasound transmission member and the guidewire conform concomitantly to the multiple bends. Bends may have any suitable angle or radius of curvature. In one embodiment, for example, one or more bends may have a radius of about 1.0 cm or less. The method may also involve applying radial force to a proximal housing of the ultrasound catheter to radially turn the distal end of the ultrasound catheter in the blood vessel.

[0021] Further aspects and specific embodiments of the invention will be described below, in reference to the attached drawing figures.

BRIEF DESCRIPTION OF THE DRAWINGS

[0022] FIG. 1 is a perspective view of an ultrasound catheter system including an ultrasound catheter device and ultrasound energy source according to an embodiment of the present invention;

DETAILED DESCRIPTION OF THE INVENTION

[0031] Ultrasound catheter devices and methods of the present invention generally provide for enhanced treatment of occlusive intravascular lesions. Catheter devices generally include a catheter body, an ultrasound energy transmission member disposed within the catheter body

and a distal head coupled with the energy transmission member and disposed adjacent the distal end of the catheter body. The ultrasound transmission member transmits ultrasound energy from an ultrasound transducer to the distal head, causing the head to vibrate and, thus, disrupt vascular occlusions. A number of improved features of such ultrasound catheter devices are described more fully below.

[0032] Referring now to Figure 1, one embodiment of an ultrasound catheter system 20 suitably includes an ultrasound catheter device 10, including a proximal end connector 12 for coupling device 10 with an ultrasound transducer 14, and an ultrasound generator 16 coupled with transducer 14 and a foot-actuated on/off switch 18 to provide ultrasonic energy to transducer 14 and, thus, to ultrasound catheter 10. Generally, catheter 10 includes an ultrasound transmission member, or wire (not shown), for transmitting energy from the transducer 14 to a distal head 26 of catheter 10. In some embodiments, transducer 14 further includes a securing device 15 for enhancing coupling of catheter 10 to transducer 14. Components of system 20 may be coupled via any suitable means, such as connecting wires of any kind, wireless connections or the like.

[0033] In addition to proximal connector 12, ultrasound catheter device 10 may include one or more other various components, such as a Y-connector 11 or the like for providing access for irrigation, guidewire passage, suction or the like. Some embodiments of device include a monorail guidewire 13, some include a proximal guidewire port 17 for over the wire guidewire delivery, and some embodiments include both. In some embodiments, Y-connector may include an irrigation port, for providing access for an irrigation tube 24. Irrigation tube 24, in some embodiments, may be used for introducing one or more fluids, applying vacuum, or both. Generally, catheter device 10 may include any suitable number of side-arms or ports for passage of a guidewire, infusing and/or withdrawing irrigation fluid, dye and/or the like, or any other suitable ports or connections. Also, ultrasound catheters 10 of the present invention may be used with any suitable proximal devices, such as any suitable ultrasound transducer 14, ultrasound generator 16, coupling device(s) and/or the like. Therefore, exemplary Figure 1 and any following descriptions of proximal apparatus or systems for use with ultrasound catheters 10 should not be interpreted to limit the scope of the present invention as defined in the appended claims.

[0034] Referring now to Figure 1A, a cross-sectional side view of one embodiment of ultrasound catheter device 10 is shown. Generally, ultrasound catheter 10 suitably includes

an elongate catheter body 22 with an ultrasound transmission member 24 disposed longitudinally through a catheter lumen 21 and ending in distal head (not shown). Catheter body 22 is generally a flexible, tubular, elongate member, having any suitable diameter and length for reaching a vascular occlusion for treatment. In one embodiment, for example, catheter body 22 preferably has an outer diameter of between about 0.5 mm and about 5.0 mm. In other embodiments, as in catheters intended for use in relatively small vessels, catheter body 22 may have an outer diameter of between about 0.25 mm and about 2.5 mm. Catheter body 22 may also have any suitable length. As discussed briefly above, for example, some ultrasound catheters have a length in the range of about 150 cm. However, any other suitable length may be used without departing from the scope of the present invention. Examples of catheter bodies similar to those which may be used in the present invention are described in U.S. Patent Nos. 5,267,954 and 5,989,208, which were previously incorporated herein by reference.

[0035] In some embodiments, catheter body 22 is made from a polymeric material. Sometimes the polymer will have a desired amount of flexibility, such as in one embodiment where catheter body 22 is made of a polymer having a flexural modulus of less than about 160 Psi. In some embodiments, such a polymer will be one of any number of polyether block amides, although other polymers may of course be used. In some embodiments, such polyether block amides may have a Shore D hardness value ranging from about 55 to about 75, while in other embodiments they may have a Shore D hardness value ranging from about 25 to about 55. In some embodiments, the polymeric material includes up to about 5 weight percent of a colorant.

[0036] In most embodiments, ultrasound transmission member 24, which may comprise a wire, wave guide or the like, extends longitudinally through catheter body lumen 21 to transmit ultrasonic energy from ultrasound transducer 14 (Fig. 1) to the distal end of catheter 10. Ultrasound transmission member 24 may be formed of any material capable of effectively transmitting ultrasonic energy from ultrasound transducer 14 to the distal end of catheter body 22, including but not limited to metals such as pure titanium or aluminum, or titanium or aluminum alloys. In accordance with one aspect of the invention, all or a portion of ultrasound transmission member 24 may be formed of one or more materials which exhibit superelastic properties. Such material(s) should preferably exhibit superelasticity consistently within the range of temperatures normally encountered by ultrasound

transmission member 24 during operation of ultrasound catheter apparatus 10. For example, in some embodiments, the material is an alloy having a tensile strength of between about 170,000 Psi and about 250,000 Psi. In some embodiments, the alloy exhibits elongation of between about 7% and about 17%. For example, in some embodiments the alloy is a nickel-titanium alloy having nickel content of between about 50.50 and about 51.50 atomic weight.

[0037] Use of superelastic metal alloys in ultrasound transmission members is described in U.S. Patent No. 5,267,954, previously incorporated by reference. Examples of superelastic metal alloys which may be used are described in detail in U.S. Patent Nos. 4,665,906 (Jervis); 4,565,589 (Harrison); 4,505,767 (Quin); and 4,337,090 (Harrison), the entire disclosures of which are hereby incorporated by reference insofar as they describe the compositions, properties, chemistries and behavior of specific metal alloys which are superelastic within the temperature range at which ultrasound transmission member 24 of the present invention operates, any and all of which superelastic metal alloys may be used to form ultrasound transmission member 24 of the present invention. In some embodiments, for example, the alloy exhibits a superelastic temperature range of about 10 degrees Celsius to about 50 degrees Celsius.

[0038] With continued reference to Figure 1A, one embodiment of proximal end connector 12 suitably includes a housing 42 with a hollow inner bore 44. Bore 44 may have a uniform inner diameter along its length or, alternatively, may have multiple segments, such as a proximal segment 47, a middle segment 45 and a distal segment 49, each of which may surround one or more various components of proximal end connector 12. Generally, proximal segment 47 of bore 44 is configured to allow coupling with ultrasound transducer 14 (not shown) via any suitable coupling means, such as a pressure fit, complementary threads or the like. Proximal segment 47 includes a sonic connector 52 for transmitting vibrational energy from transducer 14 to ultrasound transmission member 24. Sonic connector 52 may be held within housing 42 by any suitable means. In some embodiments, for example, a dowel pin may extend through sonic connector 52 to hold it within housing 42. In another embodiment, sonic connector 52 may be secured within housing 42 by means of a cavity in housing 42.

[0039] Middle segment 45 of bore 44, in some embodiments, may surround a portion of sonic connector 52, while in other embodiments, sonic connector 52 may be housed only within proximal segment 47. Sonic connector 52 is coupled with the proximal end of

ultrasound transmission member 24 by any suitable means for transmitting ultrasound energy to transmission member 24 from transducer 14. Absorber members 50, such as O-rings, surround a portion of ultrasound transmission member 24 for providing absorption of transverse vibration. Absorber members 50 may be used in any number or combination and have and suitable size and configuration, depending on the desired level of vibration absorption or dampening. Alternatively or additionally, other dampening structures may be used. Thus, the invention is not limited to the combination shown in Figure 1A.

[0040] Distal segment 49 of bore 44 typically surrounds a portion of ultrasound transmission member 24 and may also contain one or more additional sets of absorber members 50. Distal segment 49 may also contain a portion of a Y-connector 11, which is coupled with the distal end of housing 42. Coupling of Y-connector 11 with the distal end of housing 42 may be accomplished via complementary threads, pressure fitting, or any other suitable means. A Y-connector lumen 48 of Y-connector 11 allows passage of ultrasound transmission member 24 and is in fluid communication with catheter body lumen 21.

[0041] Generally, pressurized fluid such as a coolant liquid may be infused through a side-arm 13 of Y-connector, through Y-connector lumen 48 and through catheter body lumen 21 so that it flows out of one or more fluid outflow apertures in distal head 26. The temperature and flow rate of such coolant liquid may be specifically controlled to maintain the temperature of ultrasound transmission member 24 at a desired temperature within its optimal working range. In particular, in embodiments of the invention wherein ultrasound transmission member 24 is formed of a metal alloy which exhibits optimal physical properties (e.g. super elasticity) within a specific range of temperatures, the temperature and flow rate of coolant liquid infused through fluid infusion side-arm 13 may be specifically controlled to maintain the temperature of ultrasound transmission member 24 within a range of temperatures at which it demonstrates its most desirable physical properties. For example, in embodiments of the invention wherein ultrasound transmission member 24 is formed of a shape memory alloy which exhibits super elasticity when in its martensite state, but which loses super elasticity as it transitions to an austenite state, it will be desirable to adjust the temperature and flow rate of the coolant liquid infused through fluid infusion side-arm 13 so as to maintain the shape memory alloy of ultrasound transmission member 24 within a temperature range at which the alloy will remain in its martensite state and will not transition to an austenite state. The temperature at which such shape memory alloys transition from a

martensite state to an austenite state is known as the "martensite transition temperature" of the material. Thus, in these embodiments, the fluid infused through side-arm 13 will be at such temperature, and will be infused at such rate, as to maintain the shape memory alloy of ultrasound transmission member 24 below its martensite transition temperature.

[0042] Referring now to Figure 2, an ultrasound catheter device 100 may be used in to treat one or more coronary arteries CA in a human heart H. Some embodiments include a flexible distal portion configured to navigate one or more bends 102 in a coronary artery CA or other vessel. In some embodiments, catheter device 100 will be positioned in a coronary artery CA or other vessel by advancing it over (or along with) a guidewire 104. Some embodiments may also include or be used with a guide catheter 106.

[0043] As mentioned above, a "tortuous blood vessel," for the purposes of this application, means a vessel having at least one bend (which may also be referred to as a "curve" or the like), having any angle of curvature. In some cases, of course, tortuous vessels also have relatively small inner diameters and multiple bends, and various embodiments of ultrasound catheter device 100 are configured to navigate multiple bends in a vessel. In some embodiments, ultrasound catheter device 100 is configured to conform to one or more bends in a vessel such that two or more components of the device bend concomitantly with one another. For example, in some embodiments, when device 100 extends through a bend in a vessel, an ultrasound transmission member and a catheter body of device 100 will bend with approximately the same angle. In some embodiments, the ultrasound transmission member, the catheter body and a guidewire extending through the catheter may all bend concomitantly to conform to a bend in a blood vessel. Such concomitant bending is in contrast with some prior art devices, wherein the ultrasound transmission member, for example, is relatively stiffer than a distal portion of the catheter body, so that when the device is placed in a bend in a blood vessel, the catheter body bends at a more acute angle than the transmission member.

[0044] Referring now to Figure 3, in one embodiment an ultrasound catheter device 110 of the present invention includes a catheter body 116 having a proximal portion 112 and a distal portion 114, an ultrasound transmission member 118, and a distal head 111. As discussed above, catheter body 116, transmission member 118 and distal head 111 may be fabricated from any suitable material(s) and may have any of a number of suitable configurations, dimensions, and the like. In fact, Figure 3 is not drawn to scale, and distal portion 114, for example, may be relatively much longer than shown in Figure 3.

[0045] Proximal portion 112 of catheter body 116 is generally stiffer than distal portion 114, such proximal portion 112 is used for pushing or steering, and distal portion 114 is sufficiently flexible to navigate through a tortuous blood vessel to reach an occlusion site. The difference in stiffness/flexibility may be achieved by using different materials for the different portions, by configuring proximal portion 112 with a thicker wall than distal portion 114, by giving proximal portion 112 a larger outer diameter, any combination of these, or any other suitable technique. In some embodiments, proximal portion 112 and distal portion 114 are made from one piece of material, or one extrusion, while in other embodiments two or more pieces of material may be joined together. Ultrasound transmission member 118 also becomes more flexible (less stiff) toward its distal end. This is typically achieved by tapering transmission member 118, and the taper may be gradual, as shown in Figure 3, or may be achieved in one or more less-gradual steps. By providing catheter body 116 and ultrasound transmission member 118 with progressively increasing flexibility toward the distal end, catheter device 110 may provide enhanced "pushability" or "steerability," while also facilitating navigation of tortuous vessels with distal portion 114.

[0046] With reference now to Figure 4, another embodiment of an ultrasound catheter device 120 includes a catheter body 126, an ultrasound transmission member 128 and a guidewire tube 124 disposed within body 126, and a distal head coupled with ultrasound transmission member 121. Guidewire tube 124 may enter catheter body 126 at any suitable location and may extend distally up to, partially through, or completely through distal head 121, as will be explained more fully below. In one embodiment, guidewire tube 124 includes at least one opening 125 disposed within catheter body 126, for allowing a guidewire 122 to contact ultrasound transmission member 128 at one or more locations. In the embodiment shown, guidewire tube 124 includes two openings 125 to allow ultrasound transmission member 128 to pass through tube 124. Any other suitable opening(s) is also contemplated within the scope of the invention. By allowing guidewire 122 to contact ultrasound transmission member 128, an amount of ultrasound energy may be transferred from transmission member 128 to guidewire 122. This transferred energy may cause guidewire 122 to vibrate, and such vibrational energy may enhance the ability of guidewire 122 to cross a vascular occlusion. In many procedures, it is often advantageous to penetrate or cross an occlusion with guidewire 122, and utilizing ultrasound energy transferred to guidewire 122 from transmission member 128 will enhance such procedures.

[0047] Referring now to Figures 5 and 6, another embodiment of an ultrasound catheter device 130 suitably includes a catheter body 136, an ultrasound transmission member 138 and a guidewire tube 134 disposed within catheter body 136, and a distal head 131 coupled with the distal ends of transmission member 128 and guidewire tube 134. In this embodiment, distal head 131 includes a guidewire lumen 135. Guidewire lumen 135 has a cavity at its proximal end for accepting the distal end of guidewire tube 134. In alternative embodiments, distal head 131 may not include a cavity, and guidewire tube 134 may abut the proximal end of distal head 131, or the cavity may extend all the way through distal head 131, so that guidewire tube 134 extends all the way through distal head 131 and is flush with the distal end of distal head 131. Also in the embodiment depicted in Figures 5 and 6, guidewire lumen 135 of distal head 131 has a longitudinal axis 139 which is not parallel to the overall longitudinal axis 137 of catheter device 130. Thus, at least a distal portion of guidewire tube 134 is also disposed on the longitudinal axis 139 that is not parallel to the catheter device's 130 longitudinal axis 137. At the same time, guidewire lumen 135 of distal head 131 exits approximately at the center of the distal end of distal head 131. Typically, it is advantageous to have guidewire 132 exit approximately the center of distal head 131, to facilitate tracking of catheter device 130 along guidewire 132. It may also be advantageous, however, to offset guidewire tube 134 within catheter body 136, so that guidewire tube 134 and ultrasound transmission member 138 may fit within a catheter body having a smaller inner diameter. Smaller diameter catheters, of course, are more easily advanced through tortuous vasculature.

[0048] Generally, any coupled components described above may be coupled by any suitable means, such as adhesives, complementary threaded members, pressure fittings, and the like. For example, distal head 131 may be coupled with ultrasound transmission member 138, guidewire tube 134, and/or catheter body 136 with any suitable adhesive substance or via welding, bonding, pressure fitting, threaded fittings or the like. Adhesives may include, but are not limited to cyanoacrylate (eg. Loctite™, Loctite Corp., Ontario, CANADA or Dron Alpha™, Borden, Inc., Columbus, OH.) or polyurethane (e.g. Dymax™, Dymax Engineering Adhesive, Torrington, CT) adhesives. Some embodiments may also include one or more anchoring members for further securing distal head 131 to the ultrasound catheter device 130. Examples of such anchoring members are described more fully in Application Serial No. 10/410617, which was previously incorporated by reference.

[0049] Referring now to Figure 7, another embodiment of an ultrasound catheter device 140 includes a catheter body 146, ultrasound transmission member 148, guidewire tube 144 and distal head 141 having a guidewire lumen 145. In this embodiment, as mentioned briefly above, guidewire lumen 145 is configured such that guidewire tube 144 extends through the whole length of distal head 141 and ends flush with the distal end of distal head 141. Generally, distal head 141 and guidewire lumen 145 may have any suitable sizes, shapes, configurations, dimensions and the like, and the invention is in no way limited by the embodiments shown.

[0050] With reference now to Figure 8, some embodiments of an ultrasound catheter device 150 include a proximal housing 152 that is fixedly coupled with a catheter body 156. Housing 152 may be a handle, a coupling member for coupling the device 150 to an ultrasound transducer, or any other suitable proximal device for allowing a user to manipulate catheter device 150. By providing fixed coupling between housing 152 and catheter body, a proximal rotational force 155a (or torque, or twisting) applied at housing 152 will be transmitted to catheter body 156 to cause the distal end of catheter body 156 and distal head 151 to rotate 155b. It has been found that torquing, twisting or rotating ultrasound catheter device 150 may facilitate navigation of the device through tortuous vasculature and/or dissolution of a vascular occlusion using the device.

[0051] Although the invention has been described above with specific reference to various embodiments and examples, it should be understood that various additions, modifications, deletions and alterations may be made to such embodiments without departing from the spirit or scope of the invention. Accordingly, it is intended that all reasonably foreseeable additions, deletions, alterations and modifications be included within the scope of the invention as defined in the following claims.

WHAT IS CLAIMED IS:

1. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:
 - an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, wherein the proximal portion is stiffer than the distal portion, and the distal portion is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body;
 - an ultrasound transmission member extending longitudinally through the lumen of the catheter body and having a proximal end and a distal end, wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end;
 - a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and
 - at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy.
2. An ultrasound catheter as in claim 1, wherein the distal portion is sufficiently flexible to pass, without kinking, through at least 5 cm of a blood vessel having at least one bend and an inner diameter of between about 2 mm and about 5 mm.
3. An ultrasound catheter as in claim 2, wherein the at least one bend has a radius of about 1.0 cm or smaller.
4. An ultrasound catheter as in claim 1, wherein cross-sectional diameter of the catheter body is less along the distal portion than along the proximal portion, and wherein a cross-sectional diameter of the ultrasound transmission wire is less near the distal end than near the proximal end.
5. An ultrasound catheter as in claim 4, wherein the cross-sectional diameter of the catheter body is between about 0.102 cm and about 0.178 cm along its proximal end and between about 0.076 cm and about 0.127 cm along its distal end, and the cross-sectional diameter of the ultrasound transmission member is between about 0.051 cm

and about 0.102 cm near its proximal end and between about 0.013 cm and about 0.038 cm near its distal end.

6. An ultrasound catheter as in claim 4, wherein a wall thickness of the catheter body is less along the distal portion than along the proximal portion.

7. An ultrasound catheter as in claim 6, wherein the wall thickness is between about 0.007 cm to about 0.020 cm along its proximal portion and about 0.005 cm to about 0.013 cm along its distal portion.

8. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided along a guidewire from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, wherein the proximal portion has a larger cross-sectional diameter than the distal portion, the proximal portion is sufficiently stiff to push the distal portion through a blood vessel having at least one bend, and the distal portion is sufficiently flexible to pass through the bend in the blood vessel;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body and having a proximal end and a distal end, wherein a cross-sectional diameter of the ultrasound transmission member is less near its distal end than near its proximal end, and a distal portion of the ultrasound transmission member is sufficiently flexible to pass through the bend in the blood vessel;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy.

9. An ultrasound catheter as in claim 8, wherein the distal portion is sufficiently flexible to pass, without kinking, through at least 5 cm of the blood vessel, wherein the blood vessel has an inner diameter of between about 2 mm and about 5 mm, and the at least one bend has a radius of about 1.0 cm or smaller.

10. An ultrasound catheter as in claim 8, wherein a wall thickness of the catheter body is less along the distal portion than along the proximal portion.

11. An ultrasound catheter as in claim 10, wherein the wall thickness is between about 0.007 cm to about 0.020 cm along its proximal portion and about 0.005 cm to about 0.013 cm along its distal portion.

12. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided along a guidewire from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, wherein the proximal portion is stiffer than the distal portion, and the distal portion is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body and having a proximal end and a distal end, wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end, and wherein the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly with at least one bend in a guidewire extended through the at least one lumen;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy.

13. An ultrasound catheter as in claim 12, wherein the distal portion of the catheter body and the ultrasound transmission wire are sufficiently flexible to conform concomitantly to multiple bends in the guidewire.

14. An ultrasound catheter as in claim 13, wherein the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly to multiple bends in a blood vessel.

15. An ultrasound catheter as in claim 14, wherein the distal portion of the catheter body, the ultrasound transmission wire and the guidewire may be passed together or sequentially through the multiple bends in the blood vessel while conforming concomitantly to the multiple bends.

16. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided along a guidewire from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion having at least one bend, and at least one lumen, wherein the proximal portion is stiffer than the distal portion, and the distal portion is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body and having a proximal end and a distal end, wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end, wherein the ultrasound transmission member conforms to the at least one bend in the distal portion of the catheter body, and wherein the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly to at least one bend in a guidewire extended through the at least one lumen;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy.

17. An ultrasound catheter as in claim 16, wherein the distal portion of the catheter body and the ultrasound transmission wire are sufficiently flexible to conform concomitantly to multiple bends in the guidewire.

18. An ultrasound catheter as in claim 17, wherein the distal portion of the catheter body and the ultrasound transmission member are sufficiently flexible to conform concomitantly to multiple bends in a blood vessel.

19. An ultrasound catheter as in claim 18, wherein the distal portion of the catheter body, the ultrasound transmission wire and the guidewire may be passed together or sequentially through the multiple bends in the blood vessel while conforming concomitantly to the multiple bends.

20. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion, at least one lumen, and a guidewire tube disposed within the lumen, wherein the proximal portion is stiffer than the distal portion;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy;

wherein the guidewire tube includes at least one opening within the catheter body for providing contact between a guidewire extending through the guidewire tube and the ultrasound transmission member.

21. An ultrasound catheter as in claim 20, wherein the distal portion of the catheter body is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body.

22. An ultrasound catheter as in claim 20, wherein the ultrasound transmission member comprises a proximal end and a distal end, and wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end.

23. An ultrasound catheter as in claim 20, wherein the guidewire contacts the ultrasound transmission wire nearer the distal end of the catheter body than a proximal end of the catheter body.

24. An ultrasound catheter as in claim 20, wherein the guidewire contacts the ultrasound transmission wire nearer a proximal end of the catheter body than the distal end of the catheter body.

25. An ultrasound catheter as in claim 20, wherein the guidewire contacts the ultrasound transmission wire near the middle of the catheter body.

26. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, wherein the proximal portion is stiffer than the distal portion;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body, the distal head including:

a guidewire aperture in a center of a distal end of the distal head; and

a guidewire lumen extending through the distal head, the guidewire lumen having a different longitudinal axis than a longitudinal axis of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy.

27. An ultrasound catheter as in claim 26, wherein the distal portion of the catheter body is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body.

28. An ultrasound catheter as in claim 26, wherein the ultrasound transmission member comprises a proximal end and a distal end, and wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end.

29. An ultrasound catheter as in claim 26, wherein the guidewire lumen includes a cavity in which a distal end of a guidewire tube of the catheter body is disposed.

30. An ultrasound catheter as in claim 29, wherein the cavity extends through the distal end of the distal head, such that the distal end of the guidewire tube is flush with the distal end of the distal head.

31. An ultrasound catheter as in claim 29, wherein the cavity extends partially through the distal head, such that the distal end of the guidewire tube is disposed proximal to the distal end of the distal head.

32. An ultrasound catheter for disrupting occlusions in blood vessels which can be guided from an access site on a patient's body to a target site adjacent an occlusion, the ultrasound catheter comprising:

an elongate flexible catheter body having a proximal portion, a distal portion and at least one lumen, wherein the proximal portion is stiffer than the distal portion, and the distal portion is more flexible near a distal end of the catheter body than near the proximal portion of the catheter body;

an ultrasound transmission member extending longitudinally through the lumen of the catheter body and having a proximal end and a distal end, wherein the ultrasound transmission member is more flexible near its distal end than near its proximal end;

a distal head coupled with the distal end of the ultrasound transmission member and disposed adjacent the distal end of the catheter body; and

at least one coupling member for coupling the ultrasound transmission member with a source of ultrasound energy, the at least one coupling member comprising a housing fixedly coupled with the proximal end of the catheter body such that torque applied to the housing is transmitted along the catheter body to its distal portion.

33. A method for disrupting an occlusion in a blood vessel, the method comprising:

advancing an ultrasound catheter through a blood vessel having at least one bend, the catheter conforming concomitantly to the at least one bend, wherein advancing includes contacting an ultrasound transmission member of the ultrasound catheter with a guidewire at one or more locations within the catheter;

positioning a distal end of the ultrasound catheter adjacent an occlusion in the blood vessel; and

transmitting ultrasound energy to the ultrasound transmission member to disrupt the occlusion into multiple occlusion fragments, wherein transmitting includes transmitting ultrasound energy to the guidewire.

34. A method as in claim 33, further including removing at least some of the occlusion fragments from the blood vessel via the ultrasound catheter

35. A method as in claim 33, wherein the ultrasound catheter is advanced along the guidewire.

36. A method as in claim 33, wherein the guidewire is passed through the catheter.

37. A method as in claim 33, wherein the catheter and the guidewire are advanced together through the blood vessel.

38. A method as in claim 33, wherein the ultrasound catheter is advanced through at least one bend having a radius of about 1.0 cm or less.

39. A method as in claim 33, wherein the ultrasound catheter and the guidewire are advanced along multiple bends in the blood vessel, wherein a catheter body of the catheter, the ultrasound transmission member and the guidewire are sufficiently flexible to conform concomitantly to the multiple bends.

40. A method as in claim 33, further comprising applying radial force to a proximal housing of the ultrasound catheter to radially turn the distal end of the ultrasound catheter in the blood vessel.
