(54) Title: USER-INTERFACES FOR AUDIO-AUGMENTED-REALITY

FIG. 4

(57) Abstract: The technology described in this document can be embodied in a computer-implemented method of controlling a wearable audio device configured to provide an audio output. The method includes receiving data indicating the wearable audio device is proximate a geographic location associated with a plurality of localized audio messages, and presenting, using one or more user-interfaces, a representation of the plurality of localized audio messages. The method also includes receiving information indicative of a selection of a portion of the one or more user interfaces, and initiating playback of one or more of the plurality of localized audio messages that correspond to the selection, on the wearable audio device.

(84) Designated States (*unless otherwise indicated, for every kind of regional protection available*): ARIPO (BW, GH, GM, KE, LR, LS, MW, MZ, NA, RW, SD, SL, ST, SZ, TZ, UG, ZM, ZW), Eurasian (AM, AZ, BY, KG, KZ, RU, TJ, TM), European (AL, AT, BE, BG, CH, CY, CZ, DE, DK, EE, ES, FI, FR, GB, GR, HR, HU, IE, IS, IT, LT, LU, LV, MC, MK, MT, NL, NO, PL, PT, RO, RS, SE, SI, SK, SM, TR), OAPI (BF, BJ, CF, CG, CI, CM, GA, GN, GQ, GW, KM, ML, MR, NE, SN, TD, TG).

USER-INTERFACES FOR AUDIO-AUGMENTED-REALITY

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Application No. 62/640,524, filed on
5 March 8, 2018, the disclosure of which is incorporated by reference in its entirety.

TECHNICAL FIELD

[0002] This disclosure generally relates to audio devices. More particularly, the disclosure
relates to audio devices, such as wearable audio devices, including a location based audio
10 module for providing location-specific audio to the user at the wearable audio device.

BACKGROUND

[0003] Various types of portable speaker devices such as headphones or other wearable
acoustic devices are used for listening to music and other audio. These devices can be
15 connected with a source device such as a smartphone, which provides geo-location
information associated with the user.

SUMMARY

[0004] In one aspect, this document describes a computer-implemented method of
20 controlling a wearable audio device configured to provide an audio output. The method
includes receiving data indicating the wearable audio device is proximate a geographic
location associated with a plurality of localized audio messages, and presenting, using one or
more user-interfaces, a representation of the plurality of localized audio messages. The
method also includes receiving information indicative of a selection of a portion of the one or
25 more user interfaces, and initiating playback of one or more of the plurality of localized audio
messages that correspond to the selection, on the wearable audio device.

[0005] In another aspect, this document describes a computing device that includes
memory and a location-based audio engine that includes one or more processing devices.
The one or more processing devices are configured to receive data indicating that a wearable
30 audio device is proximate a geographic location associated with a plurality of localized audio
messages, and present, using one or more user-interfaces, a representation of the plurality of
localized audio messages. The one or more processing devices are further configured to
receive information indicative of a selection of a portion of the one or more user interfaces,

and initiate playback of one or more of the plurality of localized audio messages that correspond to the selection, on the wearable audio device.

[0006] Implementations of the above aspects can include one or more of the following features. The one or more user-interfaces can include an audio-based interface in which audio clips are presented to the user based on a gaze direction of a user of the wearable audio device. A volume of playback of an audio clip can be a function of the gaze direction of the user. The one or more user-interfaces can include an audio-based interface in which audio clips are binaurally played back on the wearable audio device such that an audio clip is perceived as coming from a location corresponding to one of the plurality of localized messages associated with the audio clip. A volume of playback of the audio clip can be a function of a distance of the location from a user of the wearable audio device. The representation of the plurality of localized audio messages can include one or more audio clips each corresponding to one of the plurality of localized audio messages. The audio clips can each include a portion of the corresponding localized audio message. Receiving the information indicative of the selection can include receiving motion sensor inputs indicating a gaze direction of a user of the wearable audio device. Receiving the information indicative of the selection can include receiving motion sensor inputs indicating a gesture of a user of the wearable audio device. Receiving the information indicative of the selection can include receiving motion sensor inputs indicating a motion of a user of the wearable audio device.

[0007] Two or more features described in this disclosure, including those described in this summary section, may be combined to form implementations not specifically described herein. The details of one or more implementations are set forth in the accompanying drawings and the description below. Other features, objects and advantages will be apparent from the description and drawings, and from the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] FIG. 1 is a block diagram depicting an example personal audio device according to various disclosed implementations.

[0009] FIG. 2 shows a schematic depiction of data flows in a system including the personal audio device of FIG. 1, connected with an audio gateway device, according to various implementations.

[0010] FIG. 3 shows a schematic depiction of an environment including a user interacting with the audio device of FIGS. 1 and 2, according to various implementations.

[0011] FIG. 4 is a diagram showing some examples of user-interfaces usable with the technology described herein.

[0012] FIG. 5 is a schematic diagram illustrating the presentation of an example user-interface in accordance with technology described herein.

5 [0013] FIG. 6 is a flowchart of an example process for controlling a wearable audio device in accordance with technology described herein.

[0014] It is noted that the drawings of the various implementations are not necessarily to scale. The drawings are intended to depict only typical aspects of the disclosure, and therefore should not be considered as limiting the scope of the implementations. In the
10 drawings, like numbering represents like elements between the drawings.

DETAILED DESCRIPTION

[0015] This disclosure is based, at least in part, on the realization that a directional audio selection system can be beneficially incorporated into a wearable audio device to provide for
15 added functionality. For example, a directional audio selection system can enable, among other things, audio source selection using gestures or inertial commands.

[0016] Commonly labeled components in the FIGURES are considered to be substantially equivalent components for the purposes of illustration, and redundant discussion of those components is omitted for clarity.

20 [0017] It has become commonplace for those who either listen to electronically provided audio (e.g., audio from an audio source such as a mobile phone, tablet, computer, CD player, radio or MP3 player), those who simply seek to be acoustically isolated from unwanted or possibly harmful sounds in a given environment, and those engaging in two-way
25 communications to employ personal audio devices to perform these functions. For those who employ headphones or headset forms of personal audio devices to listen to electronically provided audio, it is commonplace for that audio to be provided with at least two audio channels (e.g., stereo audio with left and right channels) to be acoustically presented with separate earpieces to each ear. For those simply seeking to be acoustically isolated from
30 unwanted or possibly harmful sounds, it has become commonplace for acoustic isolation to be achieved through the use of active noise reduction (ANR) techniques based on the acoustic output of anti-noise sounds in addition to passive noise reduction (PNR) techniques based on sound absorbing and/or reflecting materials. Further, it is commonplace to combine ANR with other audio functions in headphones.

[0018] Aspects and implementations disclosed herein may be applicable to a wide variety of personal audio devices, such as a portable speaker, headphones, and wearable audio devices in various form factors, such as watches, glasses, neck-worn speakers, shoulder-worn speakers, body-worn speakers, etc. Unless specified otherwise, the term headphone, as used in this document, includes various types of personal audio devices such as around-the-ear, over-the-ear and in-ear headsets, earphones, earbuds, hearing aids, or other wireless-enabled audio devices structured to be positioned near, around or within one or both ears of a user. Unless specified otherwise, the term wearable audio device, as used in this document, includes headphones and various other types of personal audio devices such as head, shoulder or body-worn acoustic devices that include one or more acoustic drivers to produce sound without contacting the ears of a user. Some particular aspects disclosed may be particularly applicable to personal (wearable) audio devices such as glasses or other head-mounted audio devices. It should be noted that although specific implementations of personal audio devices primarily serving the purpose of acoustically outputting audio are presented with some degree of detail, such presentations of specific implementations are intended to facilitate understanding through provision of examples and should not be taken as limiting either the scope of disclosure or the scope of claim coverage.

[0019] Aspects and implementations disclosed herein may be applicable to personal audio devices that either do or do not support two-way communications, and either do or do not support active noise reduction (ANR). For personal audio devices that do support either two-way communications or ANR, it is intended that what is disclosed and claimed herein is applicable to a personal audio device incorporating one or more microphones disposed on a portion of the personal audio device that remains outside an ear when in use (e.g., feedforward microphones), on a portion that is inserted into a portion of an ear when in use (e.g., feedback microphones), or disposed on both of such portions. Still other implementations of personal audio devices to which what is disclosed and what is claimed herein is applicable will be apparent to those skilled in the art.

[0020] FIG. 1 is a block diagram of an example of a personal audio device 10 having two earpieces 12A and 12B, each configured to direct sound towards an ear of a user. Reference numbers appended with an “A” or a “B” indicate a correspondence of the identified feature with a particular one of the earpieces 12 (e.g., a left earpiece 12A and a right earpiece 12B). Each earpiece 12 includes a casing 14 that defines a cavity 16. In some examples, one or more internal microphones (inner microphone) 18 may be disposed within cavity 16. In implementations where personal audio device 10 is ear-mountable, an ear coupling 20 (e.g.,

an ear tip or ear cushion) attached to the casing 14 surrounds an opening to the cavity 16. A passage 22 is formed through the ear coupling 20 and communicates with the opening to the cavity 16. In some examples, an outer microphone 24 is disposed on the casing in a manner that permits acoustic coupling to the environment external to the casing.

5 [0021] In implementations that include ANR, the inner microphone 18 may be a feedback microphone and the outer microphone 24 may be a feedforward microphone. In such implementations, each earphone 12 includes an ANR circuit 26 that is in communication with the inner and outer microphones 18 and 24. The ANR circuit 26 receives an inner signal generated by the inner microphone 18 and an outer signal generated by the outer microphone
10 24 and performs an ANR process for the corresponding earpiece 12. The process includes providing a signal to an electroacoustic transducer (e.g., speaker) 28 disposed in the cavity 16 to generate an anti-noise acoustic signal that reduces or substantially prevents sound from one or more acoustic noise sources that are external to the earphone 12 from being heard by the user. As described herein, in addition to providing an anti-noise acoustic signal,
15 electroacoustic transducer 28 can utilize its sound-radiating surface for providing an audio output for playback, e.g., for a continuous audio feed.

[0022] A control circuit 30 is in communication with the inner microphones 18, outer microphones 24, and electroacoustic transducers 28, and receives the inner and/or outer microphone signals. In certain examples, the control circuit 30 includes a microcontroller or
20 processor having a digital signal processor (DSP), and the inner signals from the two inner microphones 18 and/or the outer signals from the two outer microphones 24 are converted to digital format by analog to digital converters. In response to the received inner and/or outer microphone signals, the control circuit 30 can take various actions. For example, audio playback may be initiated, paused or resumed, a notification to a user (e.g., wearer) may be
25 provided or altered, and a device in communication with the personal audio device may be controlled. The personal audio device 10 also includes a power source 32. The control circuit 30 and power source 32 may be in one or both of the earpieces 12 or may be in a separate housing in communication with the earpieces 12. The personal audio device 10 may also include a network interface 34 to provide communication between the personal audio
30 device 10 and one or more audio sources and other personal audio devices. The network interface 34 may be wired (e.g., Ethernet) or wireless (e.g., employ a wireless communication protocol such as IEEE 802.11, Bluetooth, Bluetooth Low Energy, or other local area network (LAN) or personal area network (PAN) protocols).

[0023] Network interface 34 is shown in phantom, as portions of the interface 34 may be located remotely from personal audio device 10. The network interface 34 can provide for communication between the personal audio device 10, audio sources and/or other networked (e.g., wireless) speaker packages and/or other audio playback devices via one or more communications protocols. The network interface 34 may provide either or both of a wireless interface and a wired interface. The wireless interface can allow the personal audio device 10 to communicate wirelessly with other devices in accordance with any communication protocol noted herein. In some particular cases, a wired interface can be used to provide network interface functions via a wired (e.g., Ethernet) connection.

[0024] In some cases, the network interface 34 may also include a network media processor for supporting, e.g., Apple AirPlay® (a proprietary protocol stack/suite developed by Apple Inc., with headquarters in Cupertino, Calif., that allows wireless streaming of audio, video, and photos, together with related metadata between devices) or other known wireless streaming services (e.g., an Internet music service such as: Pandora®, a radio station provided by Pandora Media, Inc. of Oakland, California, USA; Spotify®, provided by Spotify USA, Inc., of New York, NY, USA); or vTuner®, provided by vTuner.com of New York, NY, USA); and network-attached storage (NAS) devices). For example, if a user connects an AirPlay® enabled device, such as an iPhone or iPad device, to the network, the user can then stream music to the network connected audio playback devices via Apple AirPlay®. Notably, the audio playback device can support audio-streaming via AirPlay® and/or DLNA's UPnP protocols, and all integrated within one device. Other digital audio coming from network packets may come straight from the network media processor through (e.g., through a USB bridge) to the control circuit 30. As noted herein, in some cases, control circuit 30 can include a processor and/or microcontroller, which can include decoders, DSP hardware/software, etc. for playing back (rendering) audio content at electroacoustic transducers 28. In some cases, network interface 34 can also include Bluetooth circuitry for Bluetooth applications (e.g., for wireless communication with a Bluetooth enabled audio source such as a smartphone or tablet). In operation, streamed data can pass from the network interface 34 to the control circuit 30, including the processor or microcontroller. The control circuit 30 can execute instructions (e.g., for performing, among other things, digital signal processing, decoding, and equalization functions), including instructions stored in a corresponding memory (which may be internal to control circuit 30 or accessible via network interface 34 or other network connection (e.g., cloud-based connection). The control circuit 30 may be implemented as a chipset of chips that include separate and multiple analog and

digital processors. The control circuit 30 may provide, for example, for coordination of other components of the personal audio device 10, such as control of user interfaces (not shown) and applications run by the personal audio device 10.

[0025] In addition to a processor and/or microcontroller, control circuit 30 can also include one or more digital-to-analog (D/A) converters for converting the digital audio signal to an analog audio signal. This audio hardware can also include one or more amplifiers which provide amplified analog audio signals to the electroacoustic transducer(s) 28, which each include a sound-radiating surface for providing an audio output for playback. In addition, the audio hardware may include circuitry for processing analog input signals to provide digital audio signals for sharing with other devices.

[0026] The memory in control circuit 30 can include, for example, flash memory and/or non-volatile random access memory (NVRAM). In some implementations, instructions (e.g., software) are stored in an information carrier. The instructions, when executed by one or more processing devices (e.g., the processor or microcontroller in control circuit 30), perform one or more processes, such as those described elsewhere herein. The instructions can also be stored by one or more storage devices, such as one or more (e.g. non-transitory) computer- or machine-readable mediums (for example, the memory, or memory on the processor/microcontroller). As described herein, the control circuit 30 (e.g., memory, or memory on the processor/microcontroller) can include a control system including instructions for controlling directional audio selection functions according to various particular implementations. It is understood that portions of the control circuit 30 (e.g., instructions) could also be stored in a remote location or in a distributed location, and could be fetched or otherwise obtained by the control circuit 30 (e.g., via any communications protocol described herein) for execution. The instructions may include instructions for controlling directional audio selection-based processes (i.e., the software modules include logic for processing inputs from a user and/or sensor system to manage audio streams), as well as digital signal processing and equalization. Additional details may be found in U.S. Patent Application Publication 20140277644, U.S. Patent Application Publication 20170098466, and U.S. Patent Application Publication 20140277639, the disclosures of which are incorporated herein by reference in their entirety. This application also incorporates by reference the following co-filed applications: (i) US Provisional Application 62/640,372, titled “Audio Content Engine for Audio Augmented Reality,” (ii) US Provisional Application 62/640,445, titled “Augmented Reality Software Development Kit,” and (iii) US Provisional Application

62/640,427, titled "Prioritizing Delivery of Location-Based Personal Audio," each of which was filed on March 8, 2018.

[0027] Personal audio device 10 can also include a sensor system 36 coupled with control circuit 30 for detecting one or more conditions of the environment proximate personal audio device 10. Sensor system 36 can include inner microphones 18 and/or outer microphones 24, sensors for detecting inertial conditions at the personal audio device and/or conditions of the environment proximate personal audio device 10 as described herein. The sensors may be on-board the personal audio device 10, or may be remote or otherwise wireless (or hard-wired) connected to the personal audio device 10. As described further herein, sensor system 36 can include a plurality of distinct sensor types for detecting inertial information, environmental information, or commands at the personal audio device 10. In particular implementations, sensor system 36 can enable detection of user movement, including movement of a user's head or other body part(s). In particular, portions of sensor system 36 may incorporate one or more movement sensors, such as accelerometers gyroscopes and/or magnetometers. In some particular implementations, sensor system 36 can include a single IMU having three-dimensional (3D) accelerometers, gyroscopes and a magnetometer.

[0028] Advances in MEMS (microelectromechanical systems) technologies have enabled the manufacture of relatively low cost multi-axis accelerometers, gyroscopes, and magnetometers of small size and having relatively low power consumption using processes based on those employed in the microelectronics industry. Developments in this field have also resulted in the creation of relatively low cost MEMS devices that combine a multi-axis accelerometer, gyroscope, and/or magnetometer (sometimes referred to as an IMU or inertial measurement unit). In employing accelerometer(s), gyroscope(s) and/or magnetometer(s) in sensor system 36 to detect movement and/or orientation, and in employing these observations concerning movement of the human body, it is possible both to detect movement imparted to the personal audio device 10 and to distinguish instances of that movement being caused by a user of that personal audio device 10 from instances of that movement being caused by some other influence. For example, where a user is traveling in a vehicle, it is possible to distinguish between movements made by the user from movement made by the vehicle. In this way, it is possible to detect that a personal audio device 10 is not in position on a user's head or body, even if that personal audio device 10 has been placed on a seat or elsewhere in moving vehicle, despite the fact that a moving vehicle will subject the personal audio device 10 to changes in acceleration and/or orientation as the vehicle moves.

[0029] In various implementations, the sensor system 36 can be located at the personal audio device 10, e.g., where an IMU is physically housed in the personal audio device 10. In some examples, the sensor system 36 (e.g., including the IMU) is configured to detect a position, or a change in position, of the personal audio device 10. This inertial information can be used to control various functions described herein. For example, the inertial information can be used to trigger a command function, such as activating an operating mode of the personal audio device 10 (e.g., a spatial audio mode), modify playback of an audio sample in the spatial audio mode, or initiate playback of audio content associated with one or more samples.

[0030] The sensor system 36 can also include one or more interface(s) for receiving commands at the personal audio device 10. For example, sensor system 36 can include an interface permitting a user to initiate functions of the personal audio device 10. In a particular example implementation, the sensor system 36 can include, or be coupled with, a capacitive touch interface for receiving tactile commands on the personal audio device 10.

[0031] In other implementations, as illustrated in the phantom depiction in FIG. 1, one or more portions of the sensor system 36 can be located at another device capable of indicating inertial information about the user of the personal audio device 10. For example, in some cases, the sensor system 36 can include an IMU physically housed in a hand-held device such as a pointer, or in another wearable audio device. In particular example implementations, at least one of the sensors in the sensor system 36 can be housed in a wearable audio device distinct from the personal audio device 10, such as where personal audio device 10 includes headphones and an IMU is located in a pair of glasses, a watch or other wearable electronic device.

[0032] According to various implementations, the audio playback devices (which may be, for example, personal audio device 10 of FIG. 1) described herein can be configured to operate in a spatial audio mode according to one or more factors. These particular implementations can allow a user to select between a plurality of choices conveyed to a user via audio, for example a plurality of audio playback sources, using directional commands detectable at the personal audio device 10, or another device connected with the personal audio device 10. In some cases, these implementations allow a user to sample a plurality of audio content sources and select audio content source(s) for playback using inertial commands. These inertial commands can be executed at the personal audio device 10 (or another connected device), and can permit control of audio playback without the need to interface with an audio gateway device (e.g., a mobile phone, personal computer (PC), e.g.,

tablet), or provide voice commands to a control device. These implementations can enhance the user experience in comparison to conventional audio systems, e.g., audio systems requiring commands at an audio gateway interface or voice commands at a control device.

[0033] As described with respect to FIG. 1, control circuit 30 can execute (and in some cases store) instructions for controlling directional audio selection in personal audio device 10 and/or other audio playback devices in a network of such devices. As shown in FIG. 2, control circuit 30 can include a location-based audio engine 210 configured to implement modifications in audio outputs at the transducer (e.g., speaker) 28 (FIG. 1) in response to a change in location-based or other conditions. In various particular embodiments, location-based audio engine 210 is configured to receive data about an environmental condition from sensor system 36, and modify the audio output at transducer(s) 28 in response to a change in the environmental condition. In particular implementations, the audio output includes a localized audio message provided at a specific geographic location, or proximate a specific geographic location, which is configured to vary with the change(s) in location and/or environmental condition. In certain cases, the localized audio message can only be provided to the user at or proximate the geographic location, providing an immersive experience at that location.

[0034] According to various implementations, control circuit 30 includes the location based audio engine 210, or otherwise accesses program code for executing processes performed by location-based audio engine 210 (e.g., via network interface 34). Location based audio engine 210 can include logic for processing sensor data 230 (e.g., receiving data indicating proximity of personal audio device 10 to a geographic location) from sensor system 36, and providing a prompt 240 to the user 225 to initiate playback of a localized audio message 250 to the user 225 at the personal audio device 10. In various implementations, in response to actuation (e.g., feedback 260) of the prompt 240 by the user 225, the location-based audio engine 210 initiates playback of the localized audio message 250 at the personal audio device 10. In additional implementations, location-based audio engine 210 can provide a beacon 255 to user 225 to indicate a direction of a localized audio message 250 based upon the sensor data 230. In some cases, this logic can include sensor data processing logic 270, library lookup logic 280 and feedback logic 290.

[0035] Location-based audio engine 210 can be coupled (e.g., wirelessly and/or via hardwired connections in personal audio device 10) with an audio library 300, which can include audio files 310 for playback (e.g., streaming) at personal audio device 10 and/or a profile system 320 including user profiles 330 about one or more user(s) 225. Audio library

300 can include any library associated with digital audio sources accessible via network interface 34 (FIG. 1) described herein, including locally stored, remotely stored or Internet-based audio libraries. Audio files 310 can additionally include audio pins or caches created by other users, and made accessible according to various functions described herein. User profiles 330 may be user-specific, community-specific, device-specific, location-specific or otherwise associated with a particular entity such as user 225. User profiles 330 can include user-defined playlists of digital music files, audio messages stored by the user 225 or another user, or other audio files available from network audio sources coupled with network interface 34 (FIG. 1), such as network attached storage (NAS) devices, and/or a DLNA server, which may be accessible to the personal audio device 10 (FIG. 1) over a local area network such as a wireless (e.g., Wi-Fi) or wired (e.g., Ethernet) home network, as well as Internet music services such as Pandora®, vTuner®, Spotify®, etc., which are accessible to the audio personal audio device 10 over a wide area network such as the Internet. In some cases, profile system 320 is located in a local server or a cloud-based server, similar to any such server described herein. User profile 330 may include information about frequently played audio files associated with user 225 or other similar users (e.g., those with common audio file listening histories, demographic traits or Internet browsing histories), “liked” or otherwise favored audio files associated with user 225 or other similar users, frequency with which particular audio files are changed by user 225 or other similar users, etc.

[0036] Profile system 320 can be associated with any community of users, e.g., a social network, subscription-based music service (such as a service providing audio library 300), and may include audio preferences, histories, etc. for user 225 as well as a plurality of other users. In particular implementations, profile system 320 can include user-specific preferences (as profiles 330) for audio messages and/or related notifications (e.g., beacons or beckoning messages). Profiles 330 can be customized according to particular user preferences, or can be shared by users with common attributes.

[0037] Location-based audio engine 210 can also be coupled with a smart device 340 that has access to a user profile (e.g., profile 330) or biometric information about user 225. It is understood that smart device 340 can include one or more personal computing devices (e.g., desktop or laptop computer), wearable smart devices (e.g., smart watch, smart glasses), a smart phone, a remote control device, a smart beacon device (e.g., smart Bluetooth beacon system), a stationary speaker system, etc. Smart device 340 can include a conventional user interface for permitting interaction with user 225, and can include one or more network interfaces for interacting with control circuit 30 and other components in personal audio

device 10 (FIG. 1). In some example implementations, smart device 340 can be utilized for: connecting personal audio device 10 to a Wi-Fi network; creating a system account for the user 225; setting up music and/or location-based audio services; browsing of content for playback; setting preset assignments on the personal audio device 10 or other audio playback devices; transport control (e.g., play/pause, fast forward/rewind, etc.) for the personal audio device 10; and selecting one or more personal audio devices 10 for content playback (e.g., single room playback or synchronized multi-room playback). In some cases smart device 340 may also be used for: music services setup; browsing of content; setting preset assignments on the audio playback devices; transport control of the audio playback devices; and selecting personal audio devices 10 (or other playback devices) for content playback. Smart device 340 can further include embedded sensors for measuring biometric information about user 225, e.g., travel, sleep or exercise patterns; body temperature; heart rate; or pace of gait (e.g., via accelerometer(s)).

[0038] As shown in FIG. 2, sensor system 36 can include one or more of the following sensors 350: a position tracking system 352; an accelerometer/gyroscope 354; a microphone (e.g., including one or more microphones) 356 (which may include or work in concert with microphones 18 and/or 24); and a wireless transceiver 358. These sensors are merely examples of sensor types that may be employed according to various implementations. It is further understood that sensor system 36 can deploy these sensors in distinct locations and distinct sub-components in order to detect particular environmental information relevant to user 225.

[0039] The position tracking system 352 can include one or more location-based detection systems such as a global positioning system (GPS) location system, a Wi-Fi location system, an infra-red (IR) location system, a Bluetooth beacon system, etc. In various additional implementations, the position tracking system 352 can include an orientation tracking system for tracking the orientation of the user 225 and/or the personal audio device 10. The orientation tracking system can include a head-tracking or body-tracking system (e.g., an optical-based tracking system, accelerometer, magnetometer, gyroscope or radar) for detecting a direction in which the user 225 is facing, as well as movement of the user 225 and the personal audio device 10. Position tracking system 352 can be configured to detect changes in the physical location of the personal audio device 10 and/or user 225 (where user 225 is separated from personal audio device 10) and provide updated sensor data 230 to the location-based audio engine 210 in order to indicate a change in the location of user 225. Position tracking system 352 can also be configured to detect the orientation of the user 225,

e.g., a direction of the user's head, or a change in the user's orientation such as a turning of the torso or an about-face movement. In some example implementations, this position tracking system 352 can detect that user 225 has moved proximate a location 400 with a localized audio message 250, or that the user 225 is looking in the direction of a location 400 with a localized audio message 250. In particular example implementations, the position tracking system 352 can utilize one or more location systems and/or orientation systems to determine the location and/or orientation of the user 225, e.g., relying upon a GPS location system for general location information and an IR location system for more precise location information, while utilizing a head or body-tracking system to detect a direction of the user's viewpoint. In any case, position tracking system 352 can provide sensor data 230 to the location-based audio engine 210 about the position (e.g., location and/or orientation) of the user 225.

[0040] The accelerometer/gyroscope 354 can include distinct accelerometer components and gyroscope components, or could be collectively housed in a single sensor component. This component may be used to sense gestures based on movement of the user's body (e.g., head, torso, limbs) while the user is wearing the personal audio device 10 or interacting with another device (e.g., smart device 340) connected with personal audio device 10. As with any sensor in sensor system 36, accelerometer/gyroscope 354 may be housed within personal audio device 10 or in another device connected to the personal audio device 10. In some example implementations, the accelerometer/gyroscope 354 can detect an acceleration of the user 225 and/or personal audio device 10 or a deceleration of the user 225 and/or personal audio device 10.

[0041] The microphone 356 (which can include one or more microphones, or a microphone array) can have similar functionality as the microphone(s) 18 and 24 shown and described with respect to FIG. 1, and may be housed within personal audio device 10 or in another device connected to the personal audio device 10. As noted herein, microphone 356 may include or otherwise utilize microphones 18 and 24 to perform functions described herein. Microphone 356 can be positioned to receive ambient audio signals (e.g., audio signals proximate personal audio device 10). In some cases, these ambient audio signals include speech/voice input from user 225 to enable voice control functionality. In some other example implementations, the microphone 356 can detect the voice of user 225 and/or of other users proximate to or interacting with user 225. In particular implementations, location-based audio engine 210 is configured to analyze one or more voice commands from user 225 (via microphone 356), and modify the localized audio message 250 based upon that

command. In some cases, the microphone 356 can permit the user 225 to record a localized audio message 250 for later playback at the location 400a, 400b, 400c, etc., by the user 225 or another user. In various particular implementations, the location-based audio engine 210 can permit the user 225 to record a localized audio message 250 to either include or exclude ambient sound (e.g., controlling ANR during recording), based upon the user preferences. In some examples, user 225 can provide a voice command to the location-based audio engine 210 via the microphone 356, e.g., to control playback of the localized audio message 250. In these cases, sensor data processing logic 270 can include logic for analyzing voice commands, including, e.g., natural language processing (NLP) logic or other similar logic.

[0042] Returning to sensor system 36, wireless transceiver 358 (comprising a transmitter and a receiver) can include, for example, a Bluetooth (BT) or Bluetooth Low Energy (BTLE) transceiver or other conventional transceiver device, and may be configured to communicate with other transceiver devices in distinct locations. In some example implementations, wireless transceiver 358 can be configured to detect an audio message (e.g., an audio message 250 such as an audio cache or pin) proximate personal audio device 10, e.g., in a local network at a geographic location or in a cloud storage system connected with the geographic location 400. For example, another user, a business establishment, government entity, tour group, etc. could leave an audio message 250 (e.g., a song; a pre-recorded message; an audio signature from: the user, another user, or an information source; an advertisement; or a notification) at particular geographic (or virtual) locations, and wireless transceiver 358 can be configured to detect this cache and prompt user 225 to initiate playback of the audio message.

[0043] As noted herein, in various implementations, the localized audio message 250 can include a pre-recorded message, a song, or an advertisement. However, in other implementations, the localized audio message can include an audio signature such as a sound, tone, line of music or a catch phrase associated with the location at which the audio message 250 is placed and/or the entity (e.g., user, information source, business) leaving the audio message 250. In some cases, the localized audio message 250 can include a signature akin to an “audio emoji”, which identifies that localized audio message 250, e.g., as an introduction and/or closing to the message. In these examples, an entity could have a signature tone or series of tones indicating the identity of that entity, which can be played before and/or after the content of the localized audio message 250. These audio signatures can be provided to the user 225 (e.g., by location-based audio engine 210) generating the localized audio message 250 as standard options, or could be customizable for each user 225. In some additional

cases, the localized audio message 250 can be editable by the user 225 generating that message. For example, the user 225 generating a localized audio message 250 can be provided with options to apply audio filters and/or other effects such as noise suppression and/or compression to edit the localized message 250 prior to making that localized message
5 250 available (or, “publishing”) to other user(s) 225 via the location-based audio engine 210. Additionally, the localized audio message 250 can enable playback control (e.g., via location-based audio engine 210), permitting the listening user 225 to control audio playback characteristics such as rewind, fast-forward, skip, accelerated playback (e.g., double-time), etc.

10 [0044] In particular example implementations, the user 225 can “drop” a localized audio message 250 such as a pin when that user 225 is physically present at a particular geographic location. For example, the user 225 can share a live audio recording, sampled using microphone 356 or another microphone to provide a snapshot of the audio at that location. This localized audio message 250 can then be associated (linked) with the geographic
15 location and made available to the user 225 or other users at a given time (or for a particular duration) when those users are also proximate to the geographic location. In other example, the localized audio message 250 can be generated from a remote location, that is, a location distinct from the particular geographic location associated with the localized audio message 250. As described herein, access to localized audio message(s) 250 and creation of such
20 message(s) 250 can be tailored to various user and group preferences. However, according to various implementations, the localized audio message 250 is only accessible to a user 225 that is proximate the geographic location associated with that message 250, e.g., a user 225 physically located within the proximity of the geographic location.

[0045] It is understood that any number of additional sensors 360 could be incorporated in
25 sensor system 36, and could include temperature sensors or humidity sensors for detecting changes in weather within environments, sensors for detecting whether a device 10 is in a case or being worn by a user, optical/laser-based sensors and/or vision systems for tracking movement or speed, light sensors for detecting time of day, additional audio sensors (e.g., microphones) for detecting human or other user speech or ambient noise, etc.

30 [0046] As noted herein, location-based audio engine 210 can include logic for performing audio control functions according to various implementations. FIG. 3 shows a flow diagram illustrating processes in location-based audio control performed by location-based audio engine 210 and its associated logic. In FIG. 3, location-based audio engine 210 receives sensor data 230 from sensor system 36 (410) indicating that the personalized audio device (or

simply, audio device) 10 is proximate a geographic location associated with a localized audio message 250. Based upon that sensor data 230, location-based audio engine 210 provides a prompt 240 to initiate playback of the localized audio message 250 at audio device 10 (420). The location based audio engine 210 can initiate playback of the localized audio message 250 in response to actuation of the prompt 240 by the user 225 (430). If the user 225 does not actuate the prompt 240, in some implementations based upon user settings (Set: Terminate), the location-based audio engine 210 can terminate the prompt (end), e.g., after a timeout period or when user 225 leaves the geographic location (435). In other cases, user settings are set (Set: Feedback) to provide a feedback prompt (e.g., in a similar manner as prompt 240 to initiate playback, or via another prompt approach described herein) to elicit feedback 260 about the localized audio message 250, method of notification, or general notification settings (440, illustrated as optional in dashed lines). Additionally, this feedback 260 can be elicited during or after playback of the localized audio message 250, even in the case that the user 225 actuates the prompt 240 and initiates playback of that message 250. The feedback from user 225 can be treated according to user settings or default settings for the location-based audio engine 210. For example, in some cases, the location-based audio engine 210 can continue playing the localized audio message 250 in response to positive feedback from the feedback prompt (450). In these cases, where the user 225 provides negative feedback relative to the feedback prompt, the location-based audio engine 210 can check user settings (e.g., in user profile(s) 330) and take corresponding action. For example, user settings can indicate that negative feedback should continue play of the localized audio message 250 (process 450, FIG. 3). In other instances, user settings can indicate that negative feedback should trigger a halt (stop) of the localized audio message 250, or revert back to a prior audio output (e.g., audio output that was interrupted by localized audio message) (process 460, FIG. 3).

[0047] As noted herein, sensor data 230 can include data about one or more location-based or environmental conditions detected by sensor system 36, and may include data about a plurality of environmental conditions. For example, sensor data 230 can include data about a position and/or orientation of the personal audio device 10 (e.g., from position tracking system 352) data about an acceleration of personal audio device 10 (e.g., from accelerometer/gyroscope 354), data about the ambient audio conditions proximate personal audio device 10 (e.g., from microphone 356) or data about nearby audio, video or other data caches (e.g., from wireless transceiver 358).

[0048] Returning to FIG. 2, in various implementations, sensor data processing logic 270 is configured to process the sensor data 230 and provide a weighted localized representation to library lookup logic 280 to enable fetching a type of audio file 310 for providing in the localized audio message 250. That is, sensor data processing logic 270 can include

5 weightings or factoring for one or more of user preferences (e.g., user profile(s) 330), sensor data about past events (e.g., position and/or acceleration information about personal audio device 10 over given periods), audio files (e.g., audio samples of user's voices, or audio signatures such as ambient audio signatures, as sampled by microphone 356), and other readily available data (e.g., a demographic profile of a plurality of users with at least one

10 common attribute with the user 225 or a categorical popularity of an audio file 310). The weighted localized representation may indicate a general characteristic of the location 400a, 400b, 400c, etc., as a combination of factors from sensor data 230, profile(s) 330 and/or information from smart device 340.

[0049] After processing the sensor data 230 with sensor data processing logic 270, library

15 lookup logic 280 can search audio library 300 for audio files 310 using the weighted localized representation from sensor data processing logic 270. Library lookup logic 280 may include a relational database with relationships between the weighted localized representation and audio files 310. As noted herein, audio library 300 can be locally stored at personal audio system 10, smart device 340, (FIG. 1) and/or stored at one or more remote or cloud-based

20 servers. Library lookup logic 280 can be continually updated based upon changes in audio library 300 in order to provide accurate, timely associations between the weighted localized representation from sensor data processing logic 270 and audio files 310. In various implementations, as noted herein, the localized audio message 250 is selected based upon a proximity of the personal audio device 10 to a particular geographic location. The library

25 lookup logic 280 can utilize the weighted localized representation to determine which, if any, localized audio message(s) 250 should be provided to the user 225 (e.g., via prompt 240 and related processes) according to the user profile 330 and/or proximity to geographic locations. For example, the library lookup logic 280 can be configured to select a localized audio message 250 from the audio files 310 when the user 225 is moving between multiple

30 locations, as well as when the user 225 approaches a location, leaves a location, or turns toward or away from a location. Additionally, as discussed herein, library lookup logic 280 can be configured to select a beacon 255 to direct the user 225 to one or more localized audio message(s) 250 based upon the weighted localized representation.

[0050] In some example implementations, location-based audio engine 210 (e.g., using sensor data processing logic 270 and/or library lookup logic 280) is configured to perform one or more of the following logic processes using sensor data 230 and/or other data accessible via profile system 320, smart device 340, etc.: speech recognition, speaker
5 identification, speaker verification, word spotting (e.g., wake word detection), speech end pointing (e.g., end of speech detection), speech segmentation (e.g., sentence boundary detection or other types of phrase segmentation), speaker diarization, affective emotion classification on voice, acoustic event detection, two-dimensional (2D) or three-dimensional (3D) beam forming, source proximity/location, volume level readings, acoustic saliency
10 maps, ambient noise level data collection, signal quality self-check, gender identification (ID), age ID, echo cancellation/barge-in/ducking, language identification, and/or other environmental classification such as environment type (e.g., small room, large room, crowded street, etc.; and quiet or loud).

[0051] In some implementations, location-based audio engine 210 is configured to work in
15 concert with sensor system 36 to continually monitor changes in one or more environmental conditions. In some cases, sensor system 36 may be set in an active mode, such as where position tracking system 352 pings nearby Wi-Fi networks to triangulate location of the personal audio device 10, or microphone 356 (or microphones 18 and/or 24) remains in a “listen” mode for particular ambient sounds. In other implementations, sensor system 36 and
20 location-based audio engine 210 can be configured in a passive mode, such as where wireless transceiver 358 detects signals transmitted from nearby transceiver devices or network devices. In still other implementations, distinct sensors in the sensor system 36 can be set in distinct modes for detecting changes in environmental conditions and transmitting updated sensor data 230 to location-based audio engine 210. For example, some sensors in sensor
25 system 36 can remain in an active mode while audio device 10 is active (e.g., powered on), while other sensors may remain in a passive mode for triggering by an event.

[0052] The weighted localized representation calculated based upon the sensor data 230 can be used to select the appropriate localized audio message 250 for playback at the audio device 10. In various implementations, the geographic location 400 is defined according to at
30 least one of a geo-fence, a local area network, a Bluetooth network, a cellular network, or a global positioning system (GPS), though other techniques may be used. According to particular implementations, the range of detection or actuation of the localized audio message 250, is defined at the time of generation of that localized audio message 250. In particular cases, the range is defined as a radius surrounding the location 400 of the localized audio

message 250. However, the range can be defined according to any variety of shapes and/or sizes. For example, the range can take the form of a radius such as a circle or other polygon shape (e.g., square, rectangle, triangle) surrounding the location 400. In some cases, the user 225 can define the range (or, radius) of the localized audio message 250 at the time of generation. In certain implementations, the radius can be centered on the location 400 of the localized audio message 250 or a point of interest. However, in other cases, the center of the radius around location 400 can be shifted by the generating user 225. Additionally, localized audio message(s) 250 can be placed at locations which are distinct from the subject of the localized audio message 250. In one example, a business located on the corner of a busy, urban intersection may prefer that its localized audio message 250 be located across the street from the business in order to capture more visitors and/or interest. In other cases, the radius can be shifted to account for a higher density of potential users 225, e.g., where a location 400 is proximate a natural barrier such as a body of water or major roadway, and users 225 are likely to be located on one side of that barrier. In various implementations, the location-based audio engine 210 can generate a weighted localized representation based upon a proximity to one or more of these indicators of geographic location. In some cases, the location-based audio engine 210 utilizes user-specific or environment-specific criteria to define “proximity” to a geographic location. For example, sensor data 230 can indicate that a user 225 is located within a one-block radius of a localized audio message 250, but that additional localized audio messages 250 are also within one block of the user 225. The location-based audio engine 210 could rely more heavily upon data from sensors having a higher degree of certainty (e.g., via weighting) to determine a closest localized audio message 250.

[0053] In some implementations, the location-based audio engine 210 can include a radius setting for determining access to prompts 240 and associated localized audio messages 250. That is, the accessible proximity to the geographic location 400 (e.g., range in which a prompt 240 will be sent, and a localized audio message 250 can be received) can be adjustable according to various implementations. In some particular aspects, the accessible proximity to the geographic location 400 is adjustable based upon a density of a geographic region, such as the population density of a region or the localized audio message density of a region. In other aspects, the accessible proximity to the geographic location 400 is adjustable based upon user profile data (in user profile(s) 330) of the user 225 or the provider of the localized audio message 250. In these examples, the user 225 could define an accessible proximity in order to avoid over-stimulation from prompts 240 in a region with a high density

of localized audio messages 250, or to avoid a message “desert”, where localized audio messages 250 are separated by significant distances. Additionally, the provider of the localized audio message 250 can define the proximity to the geographic location. This scenario could be useful for an advertiser or proprietor looking to draw users 225 toward a particular location, such as with localized audio message(s) 250 about product sales, time-sensitive offers, or events. In other implementations, default settings or common settings can be used to define the proximity to a geographic location of the localized audio message 250. In still other implementations, a provider of the localized audio message(s) 250 can adjust the accessible radius of those messages 250, and in particular cases, could provide payment or other crediting to expand or contract that radius.

[0054] In some implementations, the location-based audio engine 210 includes a directional audio selection engine 242 that is configured to select one or more audio files 310 for delivery to the device 10 based on a direction of gaze of the user 225. In some implementations, the audio files 310 selected by the directional audio selection engine 242 can be settings-specific, location-specific or otherwise tailored to particular user experiences. In some cases, directional audio selection engine 242 selects, for presentation to the user, one or more audio files 310 that are related to a particular location, e.g., when the user approaches that location. In example implementations, when a user is at an intersection, directional audio selection engine 242 can present audio prompts, beacons or other indicators to the user based upon the direction in which the user is facing (detected according to various implementations described herein). For example, when the user at an intersection activates the spatial audio mode (or has already activated the spatial audio mode or otherwise triggers settings to activate spatial audio mode), looking left can provide an audio sample (e.g., an audio prompt or audio beacon) indicating areas of interest in that direction. Looking right can trigger directional audio selection engine 242 to provide an audio sample indicating areas of interest in that direction. Additionally, looking straight ahead can trigger directional audio selection engine 242 to provide an audio sample indicating areas of interest in that direction. In these cases, an audio sample can provide introductory information about audio content 265 associated with one or more of the directions. In the intersection example: a) when looking right (during operation of the spatial audio mode), directional audio selection engine 242 can provide an audio sample such as: “Fenway Park is 0.5 miles from your current location in this direction; nod your head to hear highlights from last night’s game”; b) when looking left (during operation of the spatial audio mode), directional audio selection engine 242 can provide an audio sample such as: “Boston Public Garden is 0.4 miles from your current

location in this direction; tap your audio device to hear fun facts about this historic public gathering place”; and/or c) when looking straight ahead (during operation of the spatial audio mode), directional audio selection engine 242 can provide an audio sample such as: “You are two blocks from Newbury Street; walk forward to hear a listing of top-rated restaurants for lunch.” It is understood that this example is merely illustrative of the various array layouts and audio sample types that can be utilized by directional audio selection engine 240 in spatial audio mode.

[0055] In particular implementations, as noted herein, audio content or audio files 310 can include any audibly presentable material that can be provided to the user after selection in the spatial audio mode. As described herein, audio files 310 can include one or more associated audio samples, which may include a portion (or all) of the corresponding audibly presentable material. That is, in certain cases, the term “audio sample” can refer to any audibly presented material associated with an audio pin, and can include a portion of the audio pin, or other audibly presented material altogether, which indicates the source of the corresponding audio pin. This sample need not be a part of the underlying audio content, and may merely serve to identify the audio content and/or its source. In some example implementations, when the user activates the spatial audio mode, directional audio selection engine 242 provides the user with audio samples in an array of spatially delineated zones. The user can select between these samples in the array to actuate additional functions of the directional audio selection engine 242, e.g., to initiate playback of the source of audio content associated with the selected audio sample. Samples (and associated content) can include music choices, navigation/direction choices, news source choices, audio messages, general information about a location, safety alerts, location-specific audio pins, audio beacons, etc. Additional description of audio pins, location-specific messages, audio beacons and related content can be found in US Provisional Patent Application No. 62/626967, which is hereby incorporated by reference in its entirety. Additional description of the directional audio selection engine can be found in US Application No. 15/908,183, titled “Directional Audio Selection,” and filed on February 28, 2018, which is incorporated herein by reference in its entirety.

[0056] In some implementation, for a particular geographic location, multiple audio pins/caches of audio information may be determined as relevant, and therefore available for delivery to an acoustic device. In such cases, the multiple audio pins may be filtered/prioritized such that an audio pin may be selected for delivery over the others at a given time. This can be done, for example, by a prioritization engine 285 disposed within the

control circuit 30. While the example in FIG. 2 shows the prioritization engine 285 disposed as a part of the location based audio engine 210, the prioritization engine 285 may also be disposed as a standalone module within the control circuit 30. The prioritization engine 285 can include one or more processing devices that are configured to filter/prioritize multiple audio pins/prompts/audio samples or other location-based audio content available for delivery to a user device 10 at a given location such that a particular audio file is delivered to the device at a given time. In some implementations, the prioritization engine 285 can be implemented as a combination of software and hardware components. In some implementations, the prioritization engine can be 285 can be include computer-readable instructions encoded on a non-transitory storage medium, the instructions being executable by one or more processing devices to provide one or more functionalities described herein.

[0057] In some implementations, the prioritization engine 285 can be configured to filter available audio content based on user-preferences indicated, for example, via the feedback 260 and/or user-input 262. For example, if a user-input 262 specifies a particular type of information (e.g., “I am looking for coffee,” “show me bookstores,” or “seafood restaurants”), audio content pertaining to such information may be prioritized over other types of audio content. In some Implementations, if the user-feedback 260 indicates a preference or dislike towards a particular type of audio content, corresponding types of audio content may be prioritized or deprioritized, respectively. For example, if the feedback 260 indicates that the user prefers Asian cuisine over Mexican, the prioritization engine audio content providing information about a Chinese restaurant may be delivered preferentially over audio content providing information about a Mexican joint. In some implementations, the user’s preferences may be determined/predicted by analyzing user-behavior. For example, the prioritization engine 285 (or another portion of the control circuit 30) can determine, based on audio detected by one or more microphones of the device 10, that the user has mentioned the word “coffee” multiple times within a few minutes. Responsive to such a determination, the prioritization engine 285 can be configured to select/prioritize audio pins pertaining to coffee shops in the vicinity of the user.

[0058] In some implementations, the prioritization engine 285 can be configured to prioritize one audio pin over another based on the geo-location of the user as well as effective radii of audio pins in the vicinity of the user. As a user moves into a new location, new audio pins may become available, and such new audio pins may be prioritized over audio pins

corresponding to a relatively more distant location. As described above, in some cases, the prioritization engine 285 can be configured to select a “teaser” audio sample to draw a user towards a specific audio pin location. In some implementations, audio pins may be filtered/prioritized based on the effective radius associated with the pins. The effective

5 "radius" of a pin (e.g., the distance from which a user would need to be for that pin to become active) may be different for different audio pins based on various factors. For example, the radius of a pin may be defined by the content creator/generator. In some cases, the ability of the content creator/generator to define a larger radius for a pin may be tied to one or more attributes associated with the creator, including, for example, the number of followers,

10 popularity of their existing pins, etc. For example, a popular content creator (e.g., as defined by the number of followers) may be allowed to define a larger radius for generated pins. In another example, positively reviewed or highly liked pins may be allowed to have a larger radius. In some implementations, the radius of generated pins may be tied to financial accounts. For example, commercial entities may be allowed to increase the effective radius

15 of their pins based on payments. In some cases, exclusivity of a pin may be represented via a small radius, such that the pin is triggered only within a small area.

[0059] In some implementations, the prioritization engine 285 can be configured to filter/prioritize audio pins based on user-preferences. In some cases, the prioritization engine 285 can be configured to adjust the radius of one or more audio pins, and select prioritize the

20 pins based on the adjusted radii of the pins. This way, the radius of the same pins can be different for different users. For example, if a first user indicates being a fan of the Boston Red Sox, the originally assigned radii of pins related to the Red Sox can be increased for that user. Similarly, if a second user indicates being a fan of the Boston Bruins, the pins related to the Bruins can be configured have increased radii for that particular user.

[0060] User preferences may be specified in various ways. For example, user-preferences may specify broad categories such as “revolutionary war history,” or “Italian food,” or something particular such as “Boston Red Sox.” In some implementations, a user may specify preferences for receiving audio pins generated by a particular content generator. For example, user-preferences corresponding to the particular user can specify that the user is

25 interested in a particular retail chain or a particular singer, and the prioritization engine 285 can be configured to prioritize content from such content providers. In some implementations, a user could “follow” or subscribe to the content generated by a particular

30

content generator, and the prioritization engine 285 can be configured to alert the user to the availability of content from the particular content generator if the user enters a geographic area where such content is available. For example, if the user subscribes to content generated by a friend, the prioritization engine 285 can be configured to check for audio pins (e.g.,
5 reviews) left by the friend whenever the user enters a new geographical location (e.g., a restaurant). In some implementations, a user could create one or more channels, streams, or feeds, and/or specify one or more favorite interests, and the prioritization engine 285 can be configured to select, filter or prioritize audio content accordingly. In some implementations, the prioritization engine 285 can be configured to select/prioritize content based on whether
10 the content provider or the user participates in a subscription plan. For example, the content from a subscribing content generator may be prioritized over non-subscribing content generators.

[0061] In some implementations, the prioritization engine 285 can be configured to select/prioritize audio content that form a part of a sequence. For example, a user could
15 specify an interest in sequential audio pins that constitute, for example, a scavenger hunt, an expedition, or a story, and the prioritization engine 285 can be configured to prioritize audio pins from such a sequence, particularly if an audio pin from such a sequence has already been delivered to the user. In some implementations, a content generating entity may use such a sequence of audio pins to promote/advertise a new product. For example, a particular chain
20 of coffee shops may have a new drink coming out at particular stores, and they may promote the drink by leaving a trail of audio pins for users to uncover access to the new drink. In some implementations, the prioritization engine 285 can be configured to alert a user to the availability of such sequences in a geographical area, if the user has indicated preference for such sequences.

[0062] In some implementations, the prioritization engine 285 can be configured to automatically present audio pins relating to user-preferred content. In some implementations, the prioritization engine 285 (or another portion of the control circuit 30) can be configured to present a user interface for navigating between the various favorites/channels/presets specified by the user. An example of such an interface is the virtual audio carousel user-
30 interface, as described in US Application No. 15/908,183, titled "Directional Audio Selection," and filed on February 28, 2018, the entire content of which is incorporated herein by reference. In some implementations, a user can use such an interface to browse through

various options to discover if any related audio pins are available in a given geo-location.

For example, standing in the North End in Boston, a user may cycle through his/her favorite audio pin feeds (e.g., Revolutionary War history, the Boston Red Sox, Italian food, Taylor Swift, and a predefined group of friends) and learn whether corresponding audio pins

5 regarding are available in the vicinity. In some implementations, the prioritization engine 285 can be configured to pre-filter the user's favorite audio pin feeds based on the location of the user. For example, based on a location of the user, the prioritization engine 285 can be configured to determine that there are no pins related to certain audio pin feeds, and thus filter such feeds out of a list presented through the user-interface

10 [0063] In some implementations, the prioritization engine 285 can be configured to select/prioritize an audio pin based on a level of importance or popularity of the content. The level of importance or popularity can be determined, for example, based on ratings or feedback from other users. In some implementations, the number of times an audio pin has been shared, upvoted, and/or favorably rated can be used as a metric for the

15 importance/popularity of the pin. In some implementations, the importance of a message for a particular user may be predicted based on, for example, using a machine learning process trained on prior messages the user has (and/or other users have) rated favorably, or messages in which the user has demonstrated interest. In some implementations, the importance of the content of an audio pin for a particular user may be determined based on the

20 generator/provider of the content. For example, pins generated or created by family, friends or other acquaintances in a user's network (as determined, for example, from social media accounts associated with the user) may be prioritized by the prioritization engine 285, based on, for example, a determination/inference that the user would like to receive content from such people. In some implementations, the prioritization engine 285 can be configured to

25 prioritize content based on user-preferences pertaining to generators/providers of content. For example, a user may specify the users whose contents are to be prioritized. The user-preferences may identify individuals (e.g., spouse, children, parents, and certain friends) or groups (e.g., social network contacts) for the prioritization engine 285 to select/prioritize content accordingly. In some implementations, the prioritization engine 285 can be

30 configured to prioritize an audio pin based on friends, family or other people (e.g., as specified via user-preferences) sharing the audio pin, suggesting the audio pin, or liking the audio pin.

[0064] In some implementations, the prioritization engine 285 (or another portion of the control circuit 30) can be configured such that audio pins are delivered to the device 10 at a

frequency in accordance with corresponding user-preferences. For example, a user may specify a limit on the number of audio pins that may be delivered (e.g., no more than one audio pin per five minutes). In some implementations, a user may place the audio device in a "mute mode" such that no audio pins are delivered when that mode is active. In some
5 implementations, the mute mode may be activated automatically, for example, based on a determination that the user is in a location/situation where he/she wouldn't want audio pins delivered (e.g., while at work, while out for a run, etc.).

[0065] In-some implementations, the prioritization engine can be configured to prioritize/filter content based on a context, as determined, for example, using information
10 collected by one or more sensors of the sensor system 36 and/or user-preferences. For example, if the prioritization engine (or another portion of the control circuit) makes a determination that a user is sightseeing in a new city for the day, the prioritization engine 285 can be configured to prioritize audio pins related to coffee/breakfast shops in the morning, pins related to fun travel facts/sightseeing after breakfast, and pins related to lunch in the
15 middle of the day. In some implementations, the prioritization engine 285 can be configured to deliver such audio pins automatically, for example, based on the time of the day, geo-location of the user, and/or other sensor inputs. In some implementations, the prioritization engine 285 can be configured to deliver such information on demand, for example, upon activation of particular modes by the user. In some implementations, the user may activate a
20 particular mode using a graphical user-interface on a connected smartphone, through a control (e.g., a button or other control) disposed on the device 10, or using a voice command such as "enter restaurant mode," "enter sightseeing mode," or "enter coffee mode," etc.

[0066] In some implementations, the prioritization engine 285 can be configured to prioritize/filter content based on a direction of gaze of a user. In such cases, the prioritization
25 engine 285 may work cooperatively with the directional audio selection engine 242 in delivering audio content. Inputs from one or more sensors of the sensor system 36 may be used in determining the gaze direction of the user and/or the direction the user is facing. For example, a combination of accelerometers, gyroscopes, and magnetometers (e.g., a three-axis accelerometer, a three-axis gyroscope, and a three-axis magnetometer), possibly in addition
30 with a position tracking system 352, may be used to determine the direction that a user is facing or looking. The accelerometers, gyroscopes, magnetometers, and possibly the position tracking system 352, may be disposed in the device 10, which may be a head-worn device such as a headphone or an eyeglass (an example of which is illustrated in U.S. Patent Application 15/884,924, titled *Eyeglass Headphones*, filed January 31, 2018, the entire

content of which is incorporated herein by reference). In one example, when a user is standing at an intersection in New York City, information from the position tracking system 352 can be used to track the location of the user, and information from a set of accelerometer, gyroscope, and magnetometer can be used to determine the direction of gaze of the user. The combination of the information can be used to deliver relevant audio content to the user. For example, if the user looks towards one particular direction from the intersection, one or more audio pins describing the points of interest along that direction may be delivered to the device 10 of the user. In another example, if the user looks down towards the ground, an audio pin containing map information about the area may be delivered (e.g., “you are standing at the intersection of street X and street y, to your right...” etc.), whereas looking up can cause delivery of weather information. In some implementations, upon determining that the user is looking towards a particular target for more than a threshold amount of time, one or more audio pins related to the target may be delivered. For example, upon determining that the user is looking towards a particular restaurant or shop, an audio pin related to the particular establishment (e.g., an advertisement, an information nugget, or other audio content) may be delivered to the device 10 of the user.

[0067] In some implementations, the prioritization engine 285 can be configured to take into account line of sight/visibility in determining which audio pins to filter/prioritize. For example, in addition to location and gaze direction information of the user, the prioritization engine 285 can be configured to determine what might be in the user's field of vision, considering, for example, the time of the day, weather, possible obstructions in the line of vision, etc. For example, a user in Paris may be determined to be looking at the Eiffel tower from a location that is a threshold distance away from the landmark. However, when closer to the Eiffel Tower, a gaze along the same direction can mean that the user is looking at something else, because the line of sight to the Eiffel Tower is blocked by buildings or other structures. In some implementations, the line-of-sight determination can be based on, for example, map data corresponding to the location of the user, and/or information captured using a camera or other sensors mounted on the device 10. In some implementations, other contextual data, e.g., weather data related to fog, rain, time of the day, etc., may be used to make a determination regarding the field of vision of the user.

[0068] In some implementations, the prioritization engine 285 can be configured to filter/prioritize audio pins based on language. For example, a user may indicate, via user-preferences, that the user is interested in pins that are in English and/or some other language. In such cases, the prioritization engine 285 can be configured to filter out or deprioritize

audio pins in other languages. In some implementations, the prioritization engine can be configured to filter/prioritize audio pins based on user behavior, as determined, for example, based on the user's location information and/or data on the user's prior interaction patterns with audio pins. For example, the prioritization engine 285 can be configured to

5 prioritize/filter audio pins based on knowledge of where a user typically is at a time of day and/or what he/she is typically doing at that time of day. This can be done, for example, using a machine-learning process configured to learn a user's habits (e.g., by using application usage data, location data, and/or data on interaction with previously delivered audio pins as the training corpus) and accordingly deliver audio pins deemed as relevant to

10 the user's location and/or activities throughout the day.

[0069] In some implementations, at least a portion of the training corpus (e.g., the application usage data) can be obtained from the user's smart phone (or another device that the user interacts with during the course of the day) and/or one or more applications installed on the smart phone. For example, a coffee shop app on a user's device can have information

15 that every day, the user visits a particular store associated with the coffee shop and orders a chai latte. This information can be used by the prioritization engine 285 to select/prioritize an audio pin created by the coffee shop. For example, a dynamically generated audio pin can be delivered to the user at the appropriate time to help the user avoid a line/wait time at the store. The audio pin could account for the current wait time (e.g., 15 minutes), and include

20 content such as "Looks like you are headed to our store to pick up your drink. Would you like us to have your chai latte ready for you in 15 minutes?" In some implementations, delivery of such content may be triggered automatically if the user subscribes to content from the particular coffee shop, or manually by activating a particular mode (e.g., a "coffee mode") for receiving audio pins. In some implementations, promotions or advertisements could be

25 delivered to a user based on location information and/or knowledge of habits. For example, the prioritization engine 285 may prioritize/select pins from competing coffee shops when a user is determined to be looking for coffee.

[0070] In some implementations, the prioritization engine 285 can be configured to select/prioritize audio pins based on whether the audio pins are private or public. For

30 example, some audio pins may be publicly available to any user who wishes to listen to them, whereas other content may be generated specifically for private use by a user or a group of user. In some implementations, a content creator (e.g., a friend of a user) may create a private review of a restaurant specifically for the particular user or a group of user that includes the particular user. In such cases the prioritization engine 285 can be configured to

select/prioritize such content for the particular user or group of users but deprioritize/filter out for users not within the group.

[0071] In some implementations, the prioritization engine 285 can be configured to catalog or archive audio pins for later delivery based on one or more criteria. For example, the prioritization engine 285 can be configured to assign a score to candidate audio pins, and candidates having a score higher than a threshold, but not selected for immediate delivery, may be archived or cataloged for later delivery. In some implementations, the user may catalog or archive one or more pins (e.g., via an appropriate user-interface), which may be selected/prioritized by the prioritization engine 285 at a later time. In some implementations, the archived/cataloged audio pins may be buffered for a period of time and/or until the user clears the pins from the buffer.

[0072] The technology described in this document can facilitate various types of user-interfaces. FIG. 4 is a diagram 500 showing some examples of such user-interfaces. In various implementations, the user-interfaces can be configured to allow a user to do one or more of the following: interact with the presented audio pins and the related content 502, dismiss presented content or save presented content for future interactions 504, share presented content 506, and create new content that may be used as a portion of an audio pin 508. One or more audio pins can first be presented or delivered (501) to a user, who can then engage with the presented content in one of the above ways for the various types of user experiences.

[0073] In some implementations, a user of the device 10 can launch an application on a connected mobile device to initiate the experience of audio pins. The mobile device can be a smart phone, tablet, or another device on which mobile applications (sometimes colloquially referred to as “apps”) may be installed and executed. In some implementations, the mobile device can be substantially similar to the smart device 340 described with reference to FIG. 2. The application executing on the mobile device can be configured to communicate with the device 10 to facilitate delivery of the audio pins and/or other audio content. The audio pins and any associated content may be delivered in various ways. In some implementations, when an audio pin is delivered to the device 10, other associated content (e.g., visual or textual content) may be delivered to the connected mobile device. For example, the audio pin can be a short promotional clip, with associated additional information being delivered to the connected mobile device. In some implementations, any additional information associated with an audio clip may be delivered to the mobile automatically. In some implementations, the additional material associated with the audio clip may be delivered to the mobile device

responsive to a user interacting or engaging with the presented audio pin. In some implementations, a user may be alerted to the delivery/availability of an audio pin or any associated content via a haptic interface. The haptic interface may be disposed on the mobile device, the device 10, or another connected device such as a smart watch, ring etc.

5 [0074] The delivery interface of the audio pins can be of various types. In some implementations, audio pins may be prioritized, delivered, and played back on the device 10 automatically, based, for example, on the location of the user. One or more of the various prioritization processes described above may be used for automatically delivering the audio pins. In some implementation, audio pins may be delivered responsive to manual requests
10 from the user, for example, using voice inputs or another input device such as ones on the eyeglass headphones described in U.S. Patent Application 15/884,924. For example, if the user activates the “coffee mode” described above, or requests information on a particular type of restaurant, relevant audio pins may be prioritized, delivered, and played back on the device 10. In another example, a user can interact with the device 10 (e.g., double-tap on an
15 eyeglass headphone) to have the relevant audio pins delivered to the device. In some implementations, a user of the device 10 may first be alerted to the presence of audio pins in the vicinity (e.g., via a haptic, visual (e.g., LED light, display on screen etc.), or audible (e.g., a chime) alert, either on the device 10 or on another connected device such as a mobile device or smart watch. The content associated with the audio pins may then be delivered responsive
20 to the user indicating an interest in the available audio pins.

[0075] The availability of audio pins may be indicated to the user in various ways. In some implementations, the volume of an audible chime for the two ears can be adjusted/weighted differently such that a user can perceive a direction of the chime. For example, chimes corresponding to audio pins located due right of the user can be played only
25 through the right speaker of the device 10, chimes corresponding to audio pins located due left of the user can be played only through the left speaker of the device 10, and chimes corresponding to pins in the angular range between these locations can be played back binaurally with appropriate weights such that the user perceives a direction associated with such pins. This can be used to alert the user to the location of the audio pin so that the user
30 may move his/her head towards the pin to interact with it. In some implementations, a volume of the chime may be adjusted to signify distance of a corresponding audio pin from the user. For example, a chime corresponding to an audio pin located close to the user can be played back at a higher volume as compared to a chime corresponding to a pin that is located further away. In some implementations, a combination of the distant-based volume and

angle-based binaural weighting can be used for playing back chimes or other audio alerting a user to location of audio pins. In some implementations, such distant-based volume and angle-based binaural weighting can also be used for playing back audio pins.

[0076] A user can engage or interact with an audio pin or a representation thereof in various ways. In some implementations, the user can interact with a particular audio pin by physically moving towards the location associated with the audio pin. For example, the playback volume associated with an audio pin can be a function of the distance of the user from the location of the audio pin, and the user can increase the playback volume of the audio pin by moving towards the pin. Moving away from the pin, on the other hand, may cause the volume to decrease, and eventually fade out completely (e.g., when the user exits the outer bounds of the area associated with the pin). Such distant-dependent playback volume of an audio pin may also provide feedback to the user about the location of the pin and the extent of the area associated with the pin. In some implementations, such feedback may be used to guide a user from one audio pin to the next in a sequence of audio pins (e.g., such as one that may be used with the scavenger hunt examples described above) to guide a user to a final location. In some implementations, such sequence of audio pins may be used, for example, to guide a user through a virtual or actual trail, to provide a guided tour of a location, or to provide guidance for reaching a particular destination. The feedback aspect can be used to alert the user if the user deviates from the target trail. In some implementations, a lack of movement may also be used to interact with an audio pin. For example, if a user simply walks past a store, an audio pin associated with the store may not be delivered to the user. However, if the user stops in front of the store and/or turns towards it, the corresponding audio pin may then be delivered.

[0077] In some implementations, location dependent playback of audio content may be used to define a virtual boundary of a “soundscape” that may be used for utilitarian and/or artistic purposes. Once a user enters or exits the area defined by the virtual boundary, the audio associated with the area may be faded in or out, respectively, through the device 10. In some cases, this can significantly improve the user-experience associated with the particular area. For example, if the user is visiting a museum and enters the section featuring Renaissance paintings, the corresponding soundscape can feature music from the same era. Once the user moves to a section featuring modern art, the corresponding soundscape can be changed accordingly. In some cases, such changing of soundscapes with location can provide an improved and more immersive audio-visual experience for a user, not just at museums, but at various indoor and outdoor locations and venues. This technique can also be

used in combination with three dimensional representations of sound, such that particular sounds seem to come from particular directions, and the user can look around and experience an immersive audio environment. This has many applications, including gaming, social communication, and entertainment.

5 [0078] In some implementations, a user may interact with delivered content using a mobile device or other connected accessory. For example, additional content associated with an audio pin may be delivered on a connected mobile device, and the user may interact with such content on the mobile device. For example, if an audio pin may simply alert the user to the existence of a discount coupon delivered on the mobile device, and the user may then use
10 the mobile device to redeem the coupon. In some implementations, an accessory device such as a smart watch, ring, fitness tracker, or another wearable device may be used to interact with an audio pin or content associated with the pin. The accessory device can include one or more motion sensors that can be used to detect gestures, movements etc. that signify specific interactions with the presented content. For example, one particular type of hand movement
15 during the playback of an audio pin can signify that the user is interested in additional information, whereas another type of hand movement can signify a lack of interest in the content of the audio pin.

[0079] In some implementations, a user may interact with an audio pin using voice inputs. For example, in response to being alerted to the presence of an audio pin, a user may opt to
20 hear the content of the audio pin via a spoken instructions such as “play the pin.” In some implementations, upon hearing the content of the audio pin, a user may request more information by saying, for example, “I would like to learn more about this.” Referring back to FIG. 2, any spoken instructions may be transmitted to the control circuit 30 as input 262 or feedback 260, such that additional content may be delivered to the device 10 as needed. In
25 some implementations, an audio pin can include conversational logic that delivers progressively more information (or stops doing so) based on spoken feedback from the user.

[0080] In some implementations, the device 10 can be used for interacting with audio pins. If the device 10 is a head-worn device (e.g., a headphone or an eyeglass headphone as described above), inclusion of a nine-axis (9D) movement sensor, such as the BMF055 from
30 Robert Bosch GmbH, enables the device to track the absolute orientation of the user’s head. As an example, the nine axes in the BMF055 are provided by a three-axis accelerometer, detecting linear motion and orientation relative to gravity, a three-axis gyroscope, detecting relative rotation, and a three-axis magnetometer, measuring orientation relative to the Earth’s magnetic field. Between these three sets of axes, the absolute direction the user is looking can

be determined. In some implementations, an absolute direction of the user's gaze may also be determined with fewer degrees of sensing. For example, if a baseline can be provided, such as by looking at a smartphone while its camera captures an image of the environment, the direction the user is looking can also be determined by allowing relative movement to be
5 used to track absolute orientation for a short time. In some cases, by tracking both the location of a user (e.g., as obtained from the GPS of the connected mobile device) and gaze direction, it may be possible to determine or predict what the user is looking at.

[0081] Leveraging the gaze direction to determine/predict what the user is looking at can be used to enable various user experiences. For example, the device 10 can be configured to
10 play sounds corresponding to a real-world location when the user looks at the location. One example of this takes the form of a message that is delivered when the user looks at a particular location. This can be an advertisement for a store the user is looking at, or an identification of a landmark. It can also be locational guidance, such as "you are looking down Boylston Street. The finish line of the Boston Marathon is 500 feet away." Social
15 networking can also be involved – friends and family can leave geotagged messages for each other, to be triggered when they arrive at or look at a particular location having personal significance. This could take the form of a memory, such as "this is where your mother and I first met," or a reminder, like "if you're going into grocery store, pick up some milk." Similarly, people participating in geocaching could leave audio packages rather than, or in
20 addition to, physical caches at target locations, to be found by anyone who discovers them while running an appropriate geocaching software application.

[0082] In another example, audio corresponding to a location is played as if it were ambient sound, but only when the user is looking at a particular object. When a visitor to Vienna looks toward the statue of Mozart, music from The Magic Flute may begin playing. If
25 they look away, it fades out, to resume when they look again at the statue. In some implementations, the direction dependent volume of the audio content can be used to direct the user's gaze. For example, the volume of audio corresponding to a particular landmark can be set such that the volume is at maximum when the user is gazing directly at the landmark, but fades out gradually as the user moves his/her gaze away from the landmark.
30 The user may use this as a feedback to make sure that the user is looking at the correct landmark and not something else in the vicinity.

[0083] In some implementations, performance of a voice personal assistant (VPA) may be improved based on information about what the user is looking at. For example, a user can simply ask "what is that building" while looking at the building, and get an answer from the

VPA. In some implementations, the VPA may provide information derived by accessing additional contextual information, such as pointing out when the user is looking at the office indicated as the location for the next appointment. In some implementations, more advanced interactions, such as identifying another person, may be possible, for example, when multiple
5 users are using compatible and networked devices. In such cases, one user may look towards another user and ask the VPA for more information on the user that he/she is looking at.

[0084] In some implementations, one or more components of the device 10 may be used in interacting with audio pins or related content. For example, one or more motion sensors of the device 10 may be used for specific user input, such as by nodding, shaking head, or
10 tapping the device. In the above examples, taking one of these actions may trigger the described audio experience, or if done in response to the initial audio experience, may cause additional action such as stopping, advancing, saving, or changing to a different message. For example, if the user looking at Mozart and hearing The Magic Flute double taps the frame of his/her audio glasses, a voice assistant (or an interactive audio pin) may explain what they are
15 listening to, but if the user swipes along the frame, the gesture may cause the music to stop playing. In other examples, information about a landmark may play only after the user taps the audio glasses, or more information may be provided if the user nods his/her head in response to a question in the initial message. A yes/no question can be answered by nodding or shaking the head. Tapping the glasses to prompt an identification of another person may
20 also be more socially acceptable than asking out loud.

[0085] Other examples include combined gestures, such as tapping the frame while looking down to be read calendar updates, and tapping the frame while looking up to be read a weather forecast. In some implementations, gazing at one direction for a threshold amount of time can trigger an interaction. For example, if a short audio clip may be played to the
25 user to provide a snippet or “teaser” information. If in response, the user gazes at the particular direction for a threshold amount of time (e.g., 3 seconds), or makes some predefined gestures, or both, additional content associated with the snippet may be played back to the user. While listening to a series of messages, such as upcoming calendar appointments or upcoming performances at a music venue, tapping or nodding the head, for
30 example, can prompt more information, while swiping forward or shaking the head can dismiss the current message and move on to the next one, and swiping backward can return to the previous event. In some implementations, gesture and gaze direction can also be combined with voice input. For example, the user may speak while touching the audio device

to give input to a VPA. Other gestures, such as looking a particular direction, can also be used to activate voice input, instead of using a wake-word or touching the device.

[0086] One or more other sensors disposed in the device 10 may also be used for implementing various types of user-interfaces, and allowing different types of user-

5 experiences. In some implementations, one or more cameras disposed in the device 10 may be used for determining the direction of gaze of the user. In some implementations, one or more inward-facing camera may be used to track the movement of the eye to determine a relative position of the eye with respect to the head of the user. This in turn may be used to determine the gaze direction for the user. In some implementations, one or more electrodes
10 disposed on a particular device 10 (e.g., an eyeglass headphone) may be used for optical or magnetic sensing of eye motion (electro-oculography) to determine a gaze direction of the user.

[0087] In some implementations, the head position/gaze direction of a user may be used for presenting a virtual user-interface, an example of which is illustrated in the schematic

15 depiction of the environment 550 in FIG. 5. Presentation of such an interface can be facilitated, for example, by the directional audio selection engine 242 described in FIG. 2. In some implementations, the directional audio selection engine 242 can provide a plurality of audio samples, information, or choices (to the user 560) corresponding with spatially delineated zones 570 in an array 580 defined relative to a physical position of the audio

20 device 10 (e.g., a wearable audio device such as glasses, in this depiction). In the case of audio samples or information, each audio sample or piece of information provided to the user can be associated with a source of audio content in the audio library 300 (FIG. 2). In some implementations, the samples of audio content can include a selection of an audio file or stream, such as a representative segment of that audio content (e.g., the chorus of a song, the
25 introduction to an audio book, a highlight from a sporting broadcast, a description of the audio content, an audio message, a description of an audio pin, an indicator of the presence of an audio pin, an audio beacon, a source of an audio message, or any other portion of one or more audio files 310). In some implementations, the sample of audio content can be the entire audio content (e.g., audio file), such as in the case of a message, audio cue, audio
30 beacon, audio pin, request for feedback, etc. In some cases, sample settings can be saved in user profile(s) 330, or default sample settings can be utilized to determine which portion(s) of audio content play as samples. In additional cases, a content provider could supply location-dependent samples, context-dependent samples, a text-to-speech application navigating a directory structure, or a mono and/or band-limited copy of content streams for playback as

samples. In certain cases, where the sample is only a portion of the audio content, a looped representative sample can be provided as the sample(s) to enhance the likelihood that the user recognizes the audio content, or louder portions of the audio content can be provided as the sample(s) to improve audibility.

[0088] With continuing reference to FIG. 2, the array 580 illustrated in FIG. 5 is a visual representation of each of the zones 570 (illustrated as distinct zones denoted by 570A, 570B, 570C, 570D, etc.) in which the audio sample, piece of information, or choice will play for the user 560. For example, based upon the physical position of the audio device 10 (e.g., as detected by the IMU or other sensor in sensor system 36), the directional audio selection engine 242 can provide distinct audio samples to the user 560 (e.g., at the audio device 10 or at another device such as the smart device 340) for playback. In some particular implementations, while in a spatial audio mode, the user 560 can move his/her body (e.g., head) between the spatially delineated zones 570, and correspondingly, the directional audio selection engine 242 can be configured to initiate playback of distinct audio samples, information, or choices corresponding to the zones 570. It is understood that these zones 570 are defined relative to a physical position of the audio device 10, such that each zone 570 can be associated with an orientation of the audio device 10. In the case of wearable audio devices, the user 560 may need only move his/her head a certain number of degrees from a first zone 570A to initiate playback of a distinct audio sample, piece of information, or choice corresponding with a distinct zone (e.g., zone 570B, 570C, 570D).

[0089] While example implementations described herein relate to head tracking between zones 570, it is understood that additional alternative implementations can employ eye tracking (e.g., via an eye tracker in sensor system 36) to permit selection of zones 570 via eye movement. In these cases, the user 560 can move his/her eyes between spatially delineated zones 570 (which may be calibrated for eye-tracking actuation), and correspondingly, the directional audio selection engine 242 can be configured to initiate playback of distinct audio samples, information, or choices corresponding with those zones 570.

[0090] In certain implementations, as illustrated in the example environment 550 in FIG. 5, the array 580 of zones 570 can include a one-dimensional array such as a linear array corresponding with user movement across one direction (e.g., head rotation). In various implementations, the number of zones 570 in the array 580 can be determined based upon the type of audio device 10 (or other device) used to perform audio selection. For example, where the directional audio selection engine 242 detects that the audio device 10 (or other selection device) is a head, neck or body-mounted audio device 10, the number of zones 570

in the array 580 can be limited to a degree of movement corresponding with that body part. In the case of a head-mounted audio device 10 such as a pair of smart glasses or headphones, the span of the array 580 can be limited, e.g., to less than 90 degrees, 120 degrees or another range. In particular examples, the span of array 580 can be limited to approximately 45-75
5 degrees from the edge of its left-most zone 570A to the edge of its right-most zone (570D in this example), and in particular cases, can span approximately 50-60 degrees. In additional implementations, the span of array 580 can be modified based upon a current position of the user 560, e.g., whether user is sitting versus standing. In certain cases, the span of array 580 can be larger for a user determined to be standing (e.g., via one or more inputs from sensor
10 system 36 such as relative distance from a floor/ceiling, rate of movement, etc.) than for a user determined to be sitting (e.g., via relative distance from floor/ceiling, lack of significant movement, etc.).

[0091] It is additionally understood that the span of array 580 can be further limited by a desired number of zone selections, based upon preferences of the user 560 or default settings.

15 For example, each zone 570 can span a certain number of degrees across a user's field of motion, so as to clearly present distinct audio sample options to the user 560. While the user 560 may be comfortably capable of up to 150 degrees of motion in a particular direction (e.g., head rotation), the user experience may be enhanced with a smaller range of motion, e.g., 50-60 degrees. Additionally, while any number of audio samples, corresponding with zones
20 570, could be presented across this range of motion, the range of each zone 570 can be set to a degree measurement providing for sufficient sampling as the user 560 moves between zones 570, e.g., 10-15 degrees per zone 570. In particular examples, the user 560 is presented with approximately 4-6 zones 570 spanning approximately 45-75 degrees (with each zone 320 spanning approximately 10-15 degrees).

25 [0092] In some implementations, the zones 570 can be arranged in an array that has two dimensions, e.g., a vertical and horizontal axis. This can allow the user 560 to initiate playback of audio samples in zones 570 along a first dimension and a second dimension. For example, the environment 550 illustrated in FIG. 3 could additionally include vertically aligned zones 570 in addition to the array 580 shown. In these cases, a set of zones 570 could
30 be added to the array 580 spanning in the vertical direction such that user 560 can tilt his/her head upward or downward to initiate playback of the audio samples corresponding with zones 570 aligned along the vertical dimension relative to one or more zones 570 in the array 580.

[0093] In additional implementations, the user 560 (e.g., via settings in profile(s) 330 or other actuation with directional audio selection engine 242), or settings in directional audio selection engine 242, can configure the layout of zones 570 in the array 580. For example, in response to initiating the spatial audio mode, directional audio selection engine 242 can present a first array 580 of zones 570 to the user 560 when user 560 is looking straight ahead (e.g., a neutral or rest position), a second (distinct) array 580 of zones 570 when the user 560 looks down, and a third (additionally distinct) array 580 of zones 570 when the user 560 looks up. In some particular example implementations, a first category of selection(s) is presented in the neutral or rest position (e.g., selections of radio stations for streaming), a second category of selection(s) is presented when the user 560 looks up (e.g., weather information for a city or region) and a third category of selection(s) is presented when the user 560 looks down (e.g., calendar or meeting information).

[0094] In some particular implementations, a size of the zones 570 in the array 580 can be equally distributed, such that the zones 570 have a uniform spatial dimension relative to a position of the audio device 10. For example, each zone 570 can span approximately 10-15 degrees from left to right (or, rotation direction), and approximately 15-30 degrees from top to bottom (or, tilt direction). However, in other cases, the zones 570 are unequally distributed in the array 580, such that there is a difference in size between at least two of the zones 570. This may be beneficial for terminal zones at end(s) of the array 580, or one or more zones proximate a center of the array 580. For example, the terminal zone(s) can be larger (e.g., 20-30 degrees in span along a direction of motion of the audio device 10) than neighboring or more central zones to permit “over-rotation” by the user 560 without exiting the spatial audio mode. This may be useful, e.g., where the audio device 10 moves beyond the physical position of an equally distributed array 580 of zones 570. In other cases, central zone(s) can be larger than their neighboring zones or terminal zones based upon user preferences, profile preferences, or suggestion algorithms (or other machine learning approaches described herein). That is, a user’s preferred, frequently played, or otherwise prioritized source of audio content could be played as a sample at central zone(s) and can be associated with a zone having a larger size than its neighboring zones. This can allow the user 560 to hear the sample of that source of audio content over a greater range of motion than lesser prioritized sources of audio content.

[0095] In addition to size differentiation in the array 580, zones 570 can be arranged in a pattern based upon one or more characteristics of the source(s) of audio content. For example, prioritized audio content can be associated with central zone(s), such that when user

560 activates the spatial audio mode, he/she encounters a central zone (or one of two central zones in the case of an even-numbered array 580 of zones 570) with an audio sample from a source of the prioritized audio content, while audio content with lower priority is available in other, peripheral zone(s). The characteristic of the source of audio content can provide the basis for patterning, such that higher priority sources are more central to the user's perspective when the spatial audio mode initiates than lower priority sources. However, in other cases, priority could be denoted in a top-to-bottom, left-to-right, corner-to-corner or other arrangement in the array 580. Additionally, the zones 570 can be arranged in chronological order (e.g., as in the associated FM radio frequencies), alphabetical order (e.g., as in artist name, song name, author, speaker, streaming station), or in accordance with the direction the user is looking (e.g., when the user looks left, information about what is to his/her left is given; when the user looks straight, information about what is straight ahead is given; and when the user looks right, information about what is to his/her right is given), etc. Further, zones 570 can be arranged by genre (e.g., audio books by genres: Suspense, Comedy, Non-Fiction, etc.), type of information source (e.g., news, weather, music, podcasts, etc.), or other category.

[0096] In some implementations, selection of the audio samples in the array 580 can be based upon the location of audio device 10. For example, the directional audio selection engine 242 can use location data (e.g., from sensor system 36, smart device 340 etc.) to determine a location of the audio device 10. Using that location data, the directional audio selection engine 242 can select one or more audio pins for the user 560. In some examples, when a user 560 initiates the spatial audio mode in a location where that user 560 has previously initiated the spatial audio mode, the directional audio selection engine 242 can be configured to provide the same set of audio samples previously available at that location. In other examples, a user 560 may have particular settings (e.g., in profile(s) 330 or default settings) dictating that particular audio content or types of audio content be provided for selection at particular locations (or location types). In these cases, directional audio selection engine 242 can be configured to receive location information (e.g., from sensor system 36) and provide a location-specific selection of audio samples based upon that location information. A user 560 can have location-specific settings dictating sources of audio content for home (e.g., a selection of relaxing playlists or stations), work (e.g., a selection of classical music playlists or stations), commute (e.g., a selection of audio books or podcasts), gym (e.g., a selection of up-tempo playlists or stations), etc. The directional audio selection engine 242 and/or the prioritization engine 285 can be configured to receive the location information

indicating a location of the audio device 10, and filter the sources of audio content according to settings (e.g., user profile(s) 330) for that location.

[0097] In some cases, each of the audio samples provided to the user 560 as he/she browses the zones 570 in the array 580 includes an audio prompt or message including a descriptor of the content in each of those audio samples. For example, as user 560 initiates the spatial audio mode, the directional audio selection engine 242 can provide (e.g., render) an audio prompt overlaid with the audio sample. In some cases, the audio prompt and the audio sample are separate audio streams. However, in various implementations, the audio prompt and the audio sample can be combined in a single audio file. The audio prompt can include identification information or any descriptor of the content in each sample, such as, “Now playing: ‘Dirty Water’ by the Standells,” or simply, “‘Dirty Water’ by the Standells.” The audio prompt can further include a request for feedback, such as a request that user 560 actuate one or more actuation mechanisms (e.g., tactile, verbal, gestural) to like, dislike or otherwise judge the audio sample. In these examples, the audio prompt could say, “Shake your head to dislike; nod your head to like,” or “Nod your head if you like this sample.” The directional audio selection engine 242 can use its feedback logic 290 to update its query and selection processes based upon the feedback from user 560.

[0098] A user may provide feedback on the audio pins or other audio contents in various ways. In some implementations, one or more gestures of the user (head nod or shake, for example) may be detected as being indicative of the user’s intent to dismiss particular audio contents, and/or stop content from being played back. In some implementations, a user may also provide such indications through one or more input devices, including, for example, a capacitive surface on the device 10, a control provided on the connected mobile device, or a control provided on another connected wearable device. For example, an eyeglass headphone can include a capacitive surface that the user may swipe on to indicate his/her feedback on an audio pin or other content. In some implementations, the user may also provide such feedback using spoken inputs.

[0099] In some implementations, the user-interfaces described herein can be used by a user to share audio content with one or more other users/devices. For example, a gesture, an interaction with an input device, or a combination of the two may be used to share an audio pin or other content with another user, such that the audio pin or content is presented on the device associated with the recipient user. For example, an audio pin representing a discount offer at a store may be shared with another person by looking at the person, and/or using one or more gestures etc. to indicate an intent to share the content. In some implementations, an

audio pin or content may be stored in a buffer (e.g., at a cloud-based storage device), and eventually shared with another user. In some implementations, audio pins or other contents may be shared through a social network associated with the user. In some implementations, a gesture, an interaction with an input device, or a combination of the two may be used to share
5 an audio pin or other content with a wireless-enabled speaker such that content being played on the device 10 may be played back on the speaker.

[00100] In some implementations, audio pins or other audio content may be created by a user using one or more of the user-interfaces described herein. For example, a user may record a short review of a restaurant, and save the review as an audio pin connected to the
10 corresponding geo-location. The audio pin thus created can be configured to be shared publicly (e.g., the pin can be made available to any user in the vicinity), or shared with particular users or group(s) of users (e.g., using a social network). In some implementations, audio pins may be created collaboratively with multiple users, for example, by adding description, information, review etc. for a geolocation or an entity located at the geolocation.

[00101] In some implementations, content can be created and shared substantially
15 simultaneously. For example, the user-interfaces described herein can allow for creation of an ad-hoc communication link between two users within an area, such that the users can have a conversation with one another even when they are not within normal hearing range of one another. In some implementations, such a communication link between the two users may be
20 created by the user's looking at one another and/or performing some predefined gestures/operations indicative of the intent to establish the communication channel. The users can then use the link to exchange spoken audio.

[00102] In some implementations, the device 10 can include one or more controls for expanding/contracting a radius over which a user wishes to explore audio pins. For example,
25 the device 10 can include a button, switch, capacitive surface, or other controls that a user can use to expand the area from which audio pins may be delivered to the user. In an example operation, a user can engage the one or more controls for a period of time until a sufficient number of audio pins are discovered in the vicinity. In some implementations, a visual representation of the corresponding area may also be presented on the display of the
30 connected mobile device. In some implementations, a user can switch between preset radial distances in defining the area in which the user wishes to explore audio pins. In some implementations, one or more controls can be provided on the device 10 to expand/contract a field of vision for the user. For example, a user may engage with such one or more controls to expand the angular range over which the user wishes to explore audio pins. The angular

range may be adjusted between a predetermined minimum (a 5° arc in front of the user, for example) and 360°.

[00103] FIG. 6 is a flowchart of an example process 600 for controlling a wearable audio device in accordance with technology described herein. In some implementations, at least a portion of the process 600 may be executed at the control circuit 30 (possibly in cooperation with the sensor system 36) described above with reference to FIG. 2. Operations of the process 600 include receiving data indicating the wearable audio device is proximate a geographic location associated with a plurality of localized audio messages (610). In some implementations, the localized audio messages can be substantially similar to the audio pins and associated contents described above. The wearable audio device can be substantially similar to the audio device 10 described above.

[00104] Operations of the process 600 also include presenting, using one or more user-interfaces, a representation of the plurality of localized audio messages (620). In some implementations, the one or more user-interfaces can include an audio-based interface in which audio clips are presented to the user based on a gaze direction of a user of the wearable audio device. This can be substantially similar to the gaze –based presentation of audio pins as described above in additional detail. For example, a volume of playback of an audio clip can be a function of the gaze direction of the user, with the volume fading out gradually as a user looks in a direction away from a location of the corresponding localized audio message or audio pin.

[00105] In some implementations, the one or more user-interfaces can include an audio-based interface in which audio clips are binaurally played back on the wearable audio device such that an audio clip is perceived as coming from a location corresponding to one of the plurality of localized messages associated with the audio clip. In such cases, a volume of playback of the audio clip can be a function of a distance of the location from a user of the wearable audio device. In some implementations, the representation of the plurality of localized audio messages can include one or more audio clips each corresponding to one of the plurality of localized audio messages. For example, the audio clips can each include a portion of the corresponding localized audio message, or audio that refers to the content of the localized audio message.

[00106] Operations of the process 600 further include receiving information indicative of a selection of a portion of the one or more user interfaces (630). In some implementations, receiving the information indicative of the selection includes receiving motion sensor inputs indicating a gaze direction of a user of the wearable audio device. For example, a user may

make a selection of an audio pin (or a corresponding representation on a user interface) by looking at the corresponding direction for a threshold amount of time. In some implementations, receiving the information indicative of the selection includes receiving motion sensor inputs indicating a gesture of a user of the wearable audio device. For example, a user may select an audio pin (or a corresponding representation on a user interface) by doing a particular type of hand motion. In some cases this can be done in conjunction with looking towards a corresponding direction. In some implementations, receiving the information indicative of the selection comprises receiving motion sensor inputs indicating a motion of a user of the wearable audio device. For example, a user may select an audio pin (or a corresponding representation on a user interface) by physically moving towards the pin. Other ways of selections (e.g., interacting with controls on a wearable device, voice inputs, etc.) are also possible, as described above in additional detail.

[00107] . Operations of the process 600 also include initiating playback of one or more of the plurality of localized audio messages that correspond to the selection, on the wearable audio device (640). For example, if the user makes a gesture, or activates a control that is indicative of the user's intent to interact further with an audio pin, the corresponding audio message can be played back to the user.

[00108] The functionality described herein, or portions thereof, and its various modifications (hereinafter "the functions") can be implemented, at least in part, via a computer program product, e.g., a computer program tangibly embodied in an information carrier, such as one or more non-transitory machine-readable media, for execution by, or to control the operation of, one or more data processing apparatus, e.g., a programmable processor, a computer, multiple computers, and/or programmable logic components.

[00109] A computer program can be written in any form of programming language, including compiled or interpreted languages, and it can be deployed in any form, including as a stand-alone program or as a module, component, subroutine, or other unit suitable for use in a computing environment. A computer program can be deployed to be executed on one computer or on multiple computers at one site or distributed across multiple sites and interconnected by a network.

[00110] Actions associated with implementing all or part of the functions can be performed by one or more programmable processors executing one or more computer programs to perform the functions of the calibration process. All or part of the functions can be implemented as, special purpose logic circuitry, e.g., an FPGA and/or an ASIC (application-specific integrated circuit). Processors suitable for the execution of a computer program

include, by way of example, both general and special purpose microprocessors, and any one or more processors of any kind of digital computer. Generally, a processor will receive instructions and data from a read-only memory or a random access memory or both.

Components of a computer include a processor for executing instructions and one or more
5 memory devices for storing instructions and data.

[0011] In various implementations, components described as being “coupled” to one another can be joined along one or more interfaces. In some implementations, these interfaces can include junctions between distinct components, and in other cases, these interfaces can include a solidly and/or integrally formed interconnection. That is, in some
10 cases, components that are “coupled” to one another can be simultaneously formed to define a single continuous member. However, in other implementations, these coupled components can be formed as separate members and be subsequently joined through known processes (e.g., soldering, fastening, ultrasonic welding, bonding). In various implementations, electronic components described as being “coupled” can be linked via conventional hard-
15 wired and/or wireless means such that these electronic components can communicate data with one another. Additionally, sub-components within a given component can be considered to be linked via conventional pathways, which may not necessarily be illustrated.

[0012] A number of implementations have been described. Nevertheless, it will be understood that additional modifications may be made without departing from the scope of
20 the inventive concepts described herein, and, accordingly, other embodiments are within the scope of the following claims.

CLAIMS

We claim:

1. A computer-implemented method of controlling a wearable audio device configured to
5 provide an audio output, the method comprising:
receiving data indicating the wearable audio device is proximate a geographic
location associated with a plurality of localized audio messages;
presenting, using one or more user-interfaces, a representation of the plurality of
localized audio messages;
10 receiving information indicative of a selection of a portion of the one or more user
interfaces; and
initiating playback of one or more of the plurality of localized audio messages that
correspond to the selection, on the wearable audio device.
- 15 2. The computer-implemented method of claim 1, wherein the one or more user-
interfaces comprise an audio-based interface in which audio clips are presented to the user
based on a gaze direction of a user of the wearable audio device.
3. The computer-implemented method of claim 2, wherein a volume of playback of an
20 audio clip is a function of the gaze direction of the user.
- 4 The computer-implemented method of claim 1, wherein the one or more user-
interfaces comprise an audio-based interface in which audio clips are binaurally played back
on the wearable audio device such that an audio clip is perceived as coming from a location
25 corresponding to one of the plurality of localized audio messages associated with the audio
clip.
5. The computer-implemented method of claim 4, wherein a volume of playback of the
audio clip is a function of a distance of the location from a user of the wearable audio device.
30
6. The computer-implemented method of claim 1, wherein the representation of the plurality
of localized audio messages comprises one or more audio clips each corresponding to one of
the plurality of localized audio messages.

7. The computer-implemented method of claim 6, wherein the audio clips each comprises a portion of the corresponding localized audio message.

8. The computer-implemented method of claim 1, wherein receiving the information
5 indicative of the selection comprises receiving motion sensor inputs indicating a gaze direction of a user of the wearable audio device.

9. The computer-implemented method of claim 1, wherein receiving the information
10 indicative of the selection comprises receiving motion sensor inputs indicating a gesture of a user of the wearable audio device.

10. The computer-implemented method of claim 1, wherein receiving the information
indicative of the selection comprises receiving motion sensor inputs indicating a motion of a
user of the wearable audio device.

15

11. A computing device comprising:

memory; and

a location based audio engine comprising one or more processing devices configured

to:

20

receive data indicating that a wearable audio device is proximate a
geographic location associated with a plurality of localized audio messages;
present, using one or more user-interfaces, a representation of the
plurality of localized audio messages;

25

receive information indicative of a selection of a portion of the one or
more user interfaces; and

initiate playback of one or more of the plurality of localized audio
messages that correspond to the selection, on the wearable audio device.

12. The computing device of claim 11, wherein one or more user-interfaces comprise an
30 audio-based interface in which audio clips are presented to the user based on a gaze direction
of a user of the wearable audio device.

13. The computing device of claim 12, wherein a volume of playback of an audio clip is a
function of the gaze direction of the user.

14 The computing device of claim 11, wherein the one or more user-interfaces comprise
an audio-based interface in which audio clips are binaurally played back on the wearable
audio device such that a played audio clip is perceived as coming from a location
5 corresponding to one of the plurality of localized audio messages associated with the audio
clip.

15 The computing device of claim 14, wherein a volume of playback of the audio clip is
a function of a distance of the location from a user of the wearable audio device.
10

16. The computing device of claim 11, wherein the representation of the plurality of localized
audio messages comprises one or more audio clips each corresponding to one of the plurality
of localized audio messages.

15 17. The computing device of claim 16, wherein the audio clips each comprises a portion of
the corresponding localized audio message.

18. The computing device of claim 11, wherein receiving the information indicative of the
selection comprises receiving motion sensor inputs indicating a gaze direction of a user of the
20 wearable audio device.

19. The computing device of claim 11, wherein receiving the information indicative of the
selection comprises receiving motion sensor inputs indicating a gesture of a user of the
wearable audio device.
25

20. The computing device of claim 11, wherein receiving the information indicative of the
selection comprises receiving motion sensor inputs indicating a motion of a user of the
wearable audio device.
