A method of surface treating a polyimide film to impart improved adhesion to metal which comprises treating the surface of a polyimide film having a biphenyltetraacarboxylic acid component by contact to a solution containing potassium permanganate and/or sodium permanganate and potassium hydroxide and/or sodium hydroxide and treating said surface with an acid.
FIG. 1

FIG. 2
SURFACE TREATMENT OF POLYIMIDE FILM AND POLYIMIDE FILM HAVING A THIN METAL LAYER

BACKGROUND OF THE INVENTION

[0001] 1. Field of the Invention

[0002] The present invention relates to an improvement in surface treatment of a polyimide film and to a polyimide film having a thin metal layer. More particularly, it relates to a method of surface treating a polyimide film to provide a thin metal layer-laminated polyimide film which exhibits improved peel strength and, even after heated or humidified, retains relatively high peel strength and to a polyimide film having a thin metal layer.

[0003] 2. Description of the Related Art

[0004] Aromatic polyimide film is widely used in electronic equipment such as cameras, computers, and liquid crystal displays.

[0005] In applying an aromatic polyimide film as a substrate material of flexible printed wiring boards (FPBs), tape automated bonding (TAB) tape carriers, etc., copper foil is bonded to the aromatic polyimide film via an adhesive such as an epoxy resin adhesive.

[0006] Although the aromatic polyimide film is excellent in heat resistance, mechanical strength and electrical characteristics, the adhesive is inferior in heat resistance and the like. It follows that the copper/polyimide laminate fails to take the full advantage of the characteristics possessed by the polyimide.

[0007] To overcome this problem, adhesiveless all-polyimide copper clad laminates have been developed. All-polyimide copper clad laminates are prepared by (a) depositing such metal as nickel or chromium on polyimide by vapor deposition and then electroplating with copper, (b) applying a polyamic acid solution to copper foil, followed by drying and imidization, or (c) heat press bonding polyimide film and copper foil via thermoplastic polyimide. However, it has been pointed out that these all-polyimide copper clad laminates have small adhesion strength or impaired electrical characteristics.

[0008] A polyimide laminate having a polyimide adhesive between polyimide film and a copper layer is known (U.S. Pat. No. 4,543,295). This technique is unapplicable to a biphenyltetraacarboxylic acid-based polyimide having a low coefficient of linear thermal expansion because of small adhesive strength achieved.

[0009] Therefore, it has been proposed to use in roll laminating a thermally fusible polyimide obtained by using a specific aromatic diamine. Nevertheless, the resulting polyimide copper clad laminates still tend to have small peel strength after allowed to stand in a humidifying condition. It has been sometimes impossible with these methods to reduce the thickness of a metal layer, or there has been difficulty in freely changing the thickness of a metal layer.

[0010] JP-A-6-21157 proposes an improved plating method, in which a polyimide film is rendered hydrophilic by surface treatment with an aqueous solution of a permanganate, such as sodium permanganate or potassium permanganate, or a hypochlorite, such as sodium hypochlorite or potassium hypochlorite. According to the publication, the treated polyimide film is electroless plated with nickel or cobalt to form a thin metal layer, which is, if desired, further electroless plated with copper, and a copper layer is formed thereon by electroplating to produce a copper-clad polyimide substrate. It is claimed that, when the copper-clad polyimide substrate is left to stand in a high temperature environment for a long time, the reduction in adhesion strength is negligible.

[0011] The polyimide film used in JP-A-6-21157 is Kapton (available from Du Pont-Toray Co., Ltd.) based on pyromellitic acid component. The present inventors have revealed that the surface treatment of JP-A-6-21157 produces no effect when applied to polyimide film based on a biphenyltetraacarboxylic acid component.

SUMMARY OF THE INVENTION

[0012] An object of the present invention is to provide a method of surface treating a polyimide film to impart improved metal adhesion so that a thin metal layer-laminated polyimide film prepared by using the treated polyimide film retains relatively high peel strength even after left to stand in a heating or humidifying condition.

[0013] Another object of the present invention is to provide a polyimide film having a thin metal layer which comprises a polyimide film having been surface treated by the method and a thin metal layer formed on the treated side of the polyimide film.

[0014] The present invention relates to a method of surface treating a polyimide film having a biphenyltetraacarboxylic acid component which comprises treating the surface of the film by contact to a solution, preferably immersion in a solution, containing at least one of potassium permanganate and sodium permanganate and at least one of potassium hydroxide and sodium hydroxide and treating the film surface with an acid thereby to improve the adhesion to metal.

[0015] The present invention also relates to a polyimide film having a thin metal layer which is composed of a polyimide film having been surface treated by the above-described method to have improved adhesion to metal and a metal layer formed on the surface-treated side of the polyimide film by vapor deposition or a combination of vapor deposition and plating.

[0016] It is important in the present invention that surface treatment of a polyimide film having a biphenyltetraacarboxylic acid component with a solution containing potassium permanganate and/or sodium permanganate and potassium hydroxide and/or sodium hydroxide by immersion, spraying or a like application method be combined with acid treatment. A laminate obtained by forming a thin metal layer on the polyimide film having a biphenyltetraacarboxylic acid component being subjected to the combined treatments exhibits improved adhesion. Even after the laminate is allowed to stand in a heating or humidifying condition, reduction in peel strength is suppressed.
BRIEF DESCRIPTION OF THE DRAWINGS

[0017] The present invention will be more particularly described with reference to the accompanying drawings, in which:

[0018] FIG. 1 is a scanning electron microscopic (SEM) image of a polyimide film having been subjected to surface treatment 1 in Example 1; and

[0019] FIG. 2 is an SEM image of an untreated polyimide film in Comparative Example 1.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0020] The present invention embraces the following preferred embodiments of the above-described surface treating method and polyimide film.

[0021] 1) The surface treating method, wherein the contact treatment is carried out by immersing the polyimide film in an aqueous solution containing potassium permanganate and/or sodium permanganate in a total concentration of 10 to 100 g/l and potassium hydroxide and/or sodium hydroxide in a total concentration of 10 to 100 g/l at 20 to 85°C, for 10 to 600 seconds.

[0022] 2) The surface treating method, wherein plasma treating the surface of the polyimide film is carried out after the acid treatment.

[0023] 3) The surface treating method, wherein the polyimide film has a multilayer structure composed of a highly heat-resistant polyimide layer based on a bisphenylethynylcarboxylic acid component having on at least one side thereof a thermoplastic polyimide layer based on a bisphenylethynylcarboxylic acid component.

[0024] 4) The polyimide film having a thin metal layer, wherein the thin metal layer has a three-layer structure composed of a metal layer formed on the surface-treated side of the polyimide film by vapor deposition, a second metal layer formed on the first metal layer by vapor deposition and/or plating, and an outermost metal layer formed on the second metal layer by plating.

[0025] 5) The polyimide film having a thin metal layer, wherein the first metal layer is made of nickel, chromium, cobalt, palladium, molybdenum, tungsten, titanium, zirconium, or a nickel-copper alloy, the first metal layer has a thickness of 1 to 30 nm, the second metal layer is made of nickel, cobalt, a nickel-cobalt alloy or copper, the second metal layer has a thickness of 0.1 to 2.0 μm, and the outermost metal layer is a copper layer having a thickness of 0 to 20 μm.

[0026] The polyimide film which can be used in the present invention preferably includes a 5 to 120 μm thick film of a polyimide prepared from an acid component comprising 3,3',4,4'-biphenyltetrahydrocarboxylic acid dianhydride (hereinafter abbreviated as s-BPDA) and, if desired, pyromellitic dianhydride (hereinafter abbreviated as PMDA) and 3,3',4,4'-benzophenonetetrahydrocarboxylic acid dianhydride (hereinafter abbreviated as BTDA) and a diamine component comprising 4,4'-diaminodiphenyl ether (hereinafter abbreviated as DADE) and, if desired, p-phenylenediamine (hereinafter abbreviated as PPD). These types of polyimide will be referred to as an s-BPDA/DADE polyimide which means the polyimide comprises s-BPDA and DADE.

[0027] The polyimide may comprise other aromatic tetracarboxylic acid dianhydrides or other aromatic diamines, e.g., 4,4'-diaminophenylmethane, as far as the physical properties inherent to the above-described polyimide are not impaired.

[0028] The aromatic ring of the above-mentioned tetracarboxylic acid dianhydrides or aromatic diamines may have a substituent, such as a hydroxyl group, a methyl group or a methoxy group.

[0029] A particularly suitable polyimide film having a biphenylethynylcarboxylic acid component is a multilayer polyimide film composed of a highly heat-resistant polyimide layer having on at least one side thereof a thermoplastic polyimide layer based on a biphenylethynylcarboxylic acid component having a glass transition temperature (Tg) of 200 to 300°C.

[0030] In view of dimensional precision and rigidity, the multilayer polyimide film suitably has a layer structure in which the biphenylethynylcarboxylic acid-based thermoplastic polyimide layer has a thickness of 1 to 10 μm, the highly heat-resistant polyimide layer has a thickness of 5 to 120 μm, and a total film has a thickness of about 7 to 125 μm.

[0031] The highly heat-resistant polyimide preferably has such heat resistance that a single film made of it has too high a Tg not to be confirmed in a temperature range below about 320°C, preferably below about 350°C. It is particularly preferred for the highly heat-resistant polyimide film to have a linear expansion coefficient of 5×10⁻⁶ to 25×10⁻⁶ cm/cm°C in a temperature range of 50 to 200°C in both MD and TD and as an average of MD and TD.

[0032] Processes for the highly heat-resistant polyimide are not limited as long as the linear expansion coefficient and the Tg of film of the product fall within the above ranges. For example, the polyimide includes a random or block copolymer having an arbitrary tetracarboxylic acid component and an arbitrary aromatic diamine component at a mole ratio of approximately 1:1, a polymer blend comprising two or more kinds of polyimides, and a copolymer obtained by preparing two or more kinds of polyamic acid solutions, mixing them, and allowing them to re-combine.

[0033] Particularly preferred highly heat-resistant polyimides are s-BPDA/PPD polyimides prepared from an acid component comprising s-BPDA and, if desired, PMDA and/or BTDA and a diamine component comprising PPD and, if desired, DADE.

[0034] The aromatic tetracarboxylic acid component providing the thermoplastic polyimide includes 2,3,3',4,4'-biphenylethynylcarboxylic acid dianhydride (hereinafter abbreviated as s-BPDA) and s-BPDA. Part of the aromatic tetracarboxylic acid component can be replaced with PMDA, BTDA, etc.

[0035] The aromatic diamine component providing the thermoplastic polyimide includes flexible aromatic diamines having a plurality of benzene rings, such as DADE, 4,4'-diaminobenzophenone, 4,4'-diaminodiphenylmethane, 2,2'-bis(4-aminophenyl)-propane, 1,3-bis(4-amino-2-hydroxybenzene), 1,3-bis(4-amino-2-hydroxybenzene), 1,4-bis(4-
Part of the aromatic diamine can be replaced with aliphatic diamines, such as 1,4-diaminobutane, 1,6-diaminohexane, 1,8-diaminooctane, 1,10-diaminodecane, and 1,12-diaminododecane, or diaminodisloxanes, such as bis(3-aminopropyl) tetramethyl-disiloxane.

In order to block the amine terminal of the thermoplastic polyimide, it is possible to use dicarboxylic acids, such as phthalic anhydride and its derivatives, hexahydrophthalic anhydride and its derivatives, succinic anhydride and its derivatives, especially phthalic anhydride.

In preparing the highly heat-resistant polyimide and the thermoplastic polyimide, the above-described acid and diamine components (and, if desired, other tetracarboxylic dianhydrides and other diamines) are allowed to react in an organic solvent at about 100°C or lower, preferably 20 to 60°C, to prepare a polyamic acid solution, called a dope solution.

In the above reaction, the tetracarboxylic dianhydride and the dicarboxylic acid are preferably used in a total amount of 0.92 to 1.1 mol, particularly 0.98 to 1.1 mol, especially 0.99 to 1.1 mol, per mole of the total diamine component.

[0040] For the purpose of suppressing gelation of the polyamic acid, a phosphorous type stabilizers, such as triphenyl phosphate or triphenyl phosphate, can be added to the polyamic acid polymerization system in an amount of 0.01 to 1% by weight based on the solid content (polymer). For immobilization acceleration a basic organic compound may be added to the dope solution as a catalyst. For example, imidazole, 2-imidazole, 1,2-dimethylimidazole, 2-phenylimidazole, etc. can be used in an amount of 0.01 to 20% by weight, particularly 0.5 to 10% by weight, based on the polyamic acid (solid content). Enabling polyimide film formation at relatively low temperature, the catalyst is used for avoiding insufficient imidation.

The dope solution for preparing a thermoplastic polyimide can further contain an organoaluminum compound, an inorganic aluminum compound or an organoaluminum compound. For example, aluminum hydroxide, aluminum triacetate, etc. may be added in an amount of 1 ppm or more, particularly 1 to 1000 ppm, in terms of metallic aluminum, based on the polyamic acid (solid content).

The organic solvent used in the preparation of the polyamic acid, whether for the highly heat-resistant polyimide or for the thermoplastic polyimide, includes N-methyl-2-pyrrolidone, N,N-dimethylformamide, N,N-dimethylacetamide, N,N-diethylacetamide, dimethyl sulfoxide, hexamethyldisiloxane, N-methylacrylamide, and cresols. These organic solvents can be used either individually or as a combination thereof.

The multilayer polyimide film is conveniently prepared by a coextrusion casting method. For example, a polyamic acid solution (dope) for a highly heat-resistant polyimide and a solution of a thermoplastic polyimide or a precursor thereof are co-extruded with the latter on one or both sides of the former and cast on a carrier, such as a mirror-finished stainless steel plate or belt, etc., and treated at 100 to 200°C into a half-dried to half-cured state. The half-dried to half-cured state means a self-supporting film state resulting from heating and/or chemical imidation.

Cocustrusion of a polyamic acid dope solution for a highly heat-resistant polyimide and that for a thermoplastic polyimide into a multilayer structure can be carried out by, for example, feeding the dopes to a three-layer coextrusion die and casting the extruded film on a carrier according to the technique disclosed in JP-A-3-180343.

The two- or three-layer extruded film is half-dried and then heated to further dry the film and induce imidation to provide a multilayer polyimide film composed of a highly heat-resistant polyimide layer (base layer) and a thermoplastic polyimide layer on at least one side, preferably both sides, of the base layer. The heating temperature is at or above the Tg of the thermoplastic polyimide and below a temperature causing deterioration of the thermoplastic polyimide, suitably 300 to 550°C, in terms of the surface temperature measured with a surface thermometer. At the heating temperature of 300 to 550°C, the heating time is preferably 1 to 60 minutes.

The highly heat-resistant polyimide base layer preferably has a thickness of 5 to 120 μm, desirably 5 to 70 μm, more desirably 5 to 40 μm. With the thickness of the base layer being smaller than 5 μm, the multilayer polyimide film may have insufficient mechanical strength or dimensional stability. Where the thickness of the base layer exceeds 120 μm, difficulties in solvent removal and imidation can result.

The thermoplastic polyimide layer or layers each preferably have a thickness of 1 to 10 μm, particularly 2 to 5 μm. A thickness smaller than 1 μm has reduced adhesion performance. A thickness greater than 10 μm is usable but produces no greater effects and rather results in reduction of heat resistance of the polyimide film.

The multilayer polyimide film preferably has a thickness of 7 to 125 μm, particularly 7 to 50 μm. A thinner film than 7 μm is difficult to handle. A thicker film than 125 μm tends to have difficulties in solvent removal and imidation.

Where the above-mentioned cocustrusion casting method is followed, the base layer and the thermoplastic polyimide layer(s) can be adhered firmly to provide a multilayer structure exhibiting satisfactory electrical and mechanical characteristics.

According to the present invention, the surface of the polyimide film having the biphenyldiacarboxylic acid component is treated with a solution containing at least one of potassium permanganate and sodium permanganate and at least one of potassium hydroxide and sodium hydroxide by contact, preferably by immersion, and then treated with an acid.

The immersion treatment is preferably performed by immersing the polyimide film in an aqueous solution at 20 to 85°C, which contains potassium permanganate and/or sodium permanganate in a total concentration of 10 to 100 g/l and potassium hydroxide and/or sodium hydroxide in a total concentration of 10 to 100 g/l for about 10 to 600
seconds. Prior to the immersion treatment, the surface of the polyimide film can be swollen with a mixed aqueous solution containing diethylene glycol monobutyl ether (a concentration of the compound is, for example, 25% by weight), ethylene glycol (a concentration of the compound is, for example, 10% by weight), and 1 to 10 g/l of sodium hydroxide. The immersion treatment may be effected either continuously or batchwise, preferably continuously.

[0052] The immersion-treated polyimide film is then treated with an acid for neutralization. Acids to be used for the acid treatment are not particularly limited. Inorganic acids such as sulfuric acid, hydrochloric acid, and nitric acid, and organic acids such as acetic acid and formic acid are useful, with sulfuric acid being suitable. The acid treating conditions are not particularly limited, either. In using sulfuric acid, for example, the acid treatment is preferably carried out with 1 to 20%, particularly 5 to 10%, sulfuric acid at 5 to 80°C for 1 second to 60 minutes. The acid-treated polyimide film is preferably washed with water.

[0053] Immediately before forming a thin metal layer on the thus treated polyimide film, it is a preferred embodiment to subject the film surface to plasma treatment to clean the surface and thereby to further improve the adhesion to metal. Plasma treatment is conveniently conducted by using helium, neon, argon, krypton, xenon, nitrogen or a mixed gas thereof under a pressure of 0.3 to 50 Pa, preferably 6 to 27 Pa. Argon gas is preferred for its low cost and high cleaning performance.

[0054] A thin metal layer can be formed on the treated side of the polyimide film, i.e., the side with improved adhesion to metal by vapor deposition or a combination of vapor deposition and electroless plating and/or electroplating to provide a polyimide film having a thin metal layer.

[0055] The thin metal layer provided on the surface-treated polyimide film can have a two-layer structure composed of a first metal layer formed on the surface-treated side of the polyimide film by vapor deposition and a second metal layer formed on the first metal layer by vapor deposition and/or plating. A third metal layer as an outermost layer can further be formed on the second metal layer by plating to make a three-layer structure.

[0056] The metal forming the first metal layer is required to provide good adhesion between the polyimide film and the second metal layer, involve no thermal diffusion, and to be strong and resistant against chemicals and heat. From this viewpoint, the metal is preferably at least one member selected from the group consisting of nickel, chromium, cobalt, palladium, molybdenum, tungsten, titanium, zirconium and a nickel-copper alloy.

[0057] Where the metal layer has a two- or three-layer structure, the first metal deposit layer preferably has a deposit thickness of 1 to 30 nm. Within this thickness range it is necessary to secure enhancement of adhesion and durability after thermal loading. If the deposit thickness is less than 1 nm, not only adhesion to the polyimide film but chemical resistance and heat resistance would be insufficient. If, on the other hand, the deposit thickness is greater than 30 nm, cohesive failure can happen inside the first metal layer, resulting in reduction of adhesion. Such a thick layer is also disadvantageous for etching efficiency.

[0058] According to the surface treating method of the present invention, a polyimide film can be provided with unevenness having a large number of projections and depressions as shown in the SEM image of FIG. 1. As a result, the metal vapor for forming the first metal deposit layer enters the depressions in the film thickness direction and deposit metal into the depressions to provide enhanced adhesion and durability after thermal loading. It is preferred for the metal vapor to enter at least 1 nm, particularly 2 nm or deeper from the surface of the polyimide film to deposit metal. The metal deposited into the surface depressions of the polyimide film is considered to produce anchoring effects for securing strength of the deposited layer.

[0059] Vapor deposition to form the first metal layer on one or both treated sides of the polyimide film is preferably carried out by vacuum evaporation, sputtering, ion plating, or ion-assisted deposition. The deposition chamber is preferably previously evacuated to a high degree of vacuum of 5x10^-4 Pa or lower. The gas pressure in sputtering is preferably 5 Pa or lower, still preferably 5x10^-4 Pa or lower, from the standpoint of processing stability and deposit film denseness. Usable gases for vapor deposition include rare gases, such as argon, neon, krypton, and helium, nitrogen, and hydrogen. Argon or nitrogen are preferred for their low cost.

[0060] In order to prevent moisture adsorbed on the film from oxidizing the metal layer and to improve denseness and uniformity of the metal layer, it is desirable that the polyimide film be pre-heated to 30 to 280°C, particularly 30 to 120°C, prior to vapor deposition. Heating temperatures above 280°C can result in wrinkling during vapor deposition or blocking of the resulting laminates due to insufficient cooling after metal layer formation. The preheating may be done with a heat roll or a heater provided in front of a deposition chamber.

[0061] It is preferable that the polyimide film be subjected to plasma treatment after preheating and immediately before vapor deposition to clean the film surface and to improve adhesion to metal.

[0062] In case where copper is deposited on the first metal layer by vapor deposition to form the second metal layer, vapor deposition is carried out by sputtering, ion plating, electron beam evaporation or a like technique. The copper deposit layer preferably has a deposit thickness of 10 nm to 5 μm, particularly 100 to 500 nm. A thinner copper layer than 10 nm will fail to perform the full function as an undercoat for plating. A thickness exceeding 5 μm leads to increased cost.

[0063] Vapor deposition for the first metal layer and that for the second metal layer on a running polyimide film can be conducted either continuously or discontinuously. For example, a polyimide film having a first metal layer depos-
ited thereon may be transported in a reverse direction and
then subjected to second vapor deposition for forming a
second metal layer. However, releasing the first metal layer
from a vacuum system tends to involve oxidation of the first
metal layer, which is unfavorable from the standpoint of
adhesive strength.

[0064] The degree of vacuum in the second vapor depo-
sition chamber is preferably previously set at 5×10⁻⁵ Pa or
lower. In the case of sputtering, the gas pressure is preferably
5 Pa or lower, particularly 5×10⁻² Pa or lower, for process-
ning stability and deposit film denseness. Usable gases for
vapor deposition include rare gases, such as argon, neon,
krypton, and helium, nitrogen, and hydrogen. Argon or
nitrogen are preferred for their low cost.

[0065] The second metal layer can be plated with copper
by electroless plating and/or electroplating to form a copper
plating layer and thereby to provide a thickened conductive
layer. The copper plating layer preferably has a thickness of
0 to 20 μm. A copper plating layer thicker than 20 μm can
result in reduction of line width precision in high-density
wiring. Such a thick copper layer is also disadvantageous for
achieving weight and size reduction of electronic compo-
ments to be mounted and from the economical consideration.

[0066] The polyimide film with a thin metal layer accord-
ing to the present invention is used as such or in the form of
roll. If necessary, it is subjected to various treatments such
as etching and reverse curling treatment, and cut to size for
use as a substrate of electronic components. For example, it
is fit for use as a substrate of FPCs, TAB tape carriers,
multi layer FPCs, and rigid flex circuit boards.

[0067] The present invention will now be illustrated in
greater detail with reference to Reference Example and
Examples, but it should be understood that the invention is
not construed as being limited thereto. Unless otherwise
noted, all the percents are by weight. A peel strength of metal
layer/polyimide laminates produced was measured as fol-
lows. Mechanical properties of the polyimide film prepared
were measured according to ASTM D882.

[0068] Measurement of Peel Strength:

[0069] A 10 mm wide test specimen was cut out of a thin
metal layer/polyimide film laminate after being allowed to
stand at room temperature for 24 hours, at 150° C. for 24
hours, at 200° C. for 24 hours, or at 121° C. and 100% RH
under 2 atms. (pressure cooker test; PCT) for 24 hours, each
after copper plating. The 90° peel strength of the specimen
was measured at a pulling speed of 50 mm/min.

REFERENCE EXAMPLE 1

[0070] Preparation of Multilayer Polyimide Film

[0071] A dope solution for highly heat-resistant polyimide
having a monomer concentration of 18% was prepared by
polymerizing PPD and s-BPDA at a molar ratio of 1:1 in
N-methyl-2-pyrrolidione. A dope solution for thermoplastic
polyimide having a monomer concentration of 18% was
prepared by polymerizing DADDE and s-BPDA at a molar
ratio of 1:1 in N-methyl-2-pyrrolidione. The two dope solu-
tions were coextruded through a film forming apparatus
equipped with a three-layer coextrusion die (multi-manifold
die), cast on a metal-made carrier, and continuously dried
with hot air at 150°C to form a solid film. The cast film was
stripped from the carrier and heated in a heating oven at a
gradually elevated temperature of from 200°C to 252°C
to remove the solvent and to imitate the polyimide precur-
sor. The resulting three-layered polyimide film was wound
into roll.

[0072] The resulting three-layered polyimide film had the
following physical properties.

[0073] Thickness structure: 3 μm/44 _82 m/3 μm (50
μm in total)

[0074] Tg of thermoplastic polyimide: 275°C C.

[0075] Volume resistivity: >1×10¹⁵ Ω-cm

[0076] Coefficient of linear thermal expansion (50 to
200°C): 10×10⁻⁶ to 20×10⁻⁶ cm/cm°C in both
MD and TD

EXAMPLE 1

[0077] 1) Treatment 1

[0078] The multilayer polyimide film prepared in Refer-
ce Example 1 was immersed in an aqueous solution
containing 60 g/l of potassium permanganate and 45 g/l of
sodium hydroxide for 1 minute, washed with water, neu-
tralized with a 50 ml/h sulfuric acid aqueous solution, and
washed with water. The SEM image of the treated side of
the polyimide film is shown in FIG. 1.

[0079] 2) Treatment 2

[0080] The film having been treated by treatment 1 was set
on a substrate holder in a sputtering chamber. After evacu-
atng the chamber to a pressure of 2×10⁻⁴ Pa or lower, argon
was introduced to a pressure of 0.67 Pa. A 13.56 MHz
radiofrequency power of 500W was applied to the electrodes
to generate plasma to give 1 minute plasma cleaning to the
film surface.

[0081] 3) Formation of Thin Metal Layer

[0082] Consecutively, chromium and then copper were
deposited in an argon atmosphere of 0.67 Pa to a deposit
thickness of 10 nm and 0.4 μm, respectively, and the film
was taken out of the chamber. The copper layer was plated
with copper by electroplating in an acid copper sulfate
aqueous solution to a deposit thickness of 20 μm.

[0083] The results of peel test of the metal layer/polyimide
laminate are shown in Table 1 below.

EXAMPLES 2 AND 3

[0084] A metal layer/polyimide laminate was obtained in
the same manner as in Example 1, except for prolonging the
immersion time of treatment 1 to 3 minutes (Example 2) or
5 minutes (Example 3). The results of peel test of the
resulting laminates are shown in Table 1.

COMPARATIVE EXAMPLE 1

[0085] A metal layer/polyimide laminate was obtained in
the same manner as in Example 1, except that treatment 1
was not carried out (treating time: 0 min). The SEM image
of the polyimide film before metal layer formation is shown
in FIG. 2.

[0086] As shown in Table 1, the peel strength, which was
initially 0.86 kg/cm, remarkably reduced after the laminate
was left to stand under conditions of 150° C×24 hrs, 200°
C×24 hrs, or PCT conditions (121° C., 100% RH, 2
atms×24 hrs).

**COMPARATIVE EXAMPLE 2**

Kapton H, a polyimide film available from Du Pont-Toray Co., Ltd., was surface treated in the same manner as in Example 1. However, the film surface underwent considerable dissolution in treatment 1 so that further treatment was impossible.

As described above, the present invention provides a biphenyltetraacarboxylic acid-based polyimide film with improved adhesion. The polyimide film of the invention provides a thin metal layer/polyimide film laminate which undergoes reduced reduction in peel strength even when allowed to stand under a heating or humidifying condition (each peel strength is not less than 0.5 kg/cm). The polyimide film having a thin metal layer according to the present invention retains relatively high peel strength even when allowed to stand under a heating or humidifying condition.

The invention being thus described, it will be obvious that the same may be varied in many ways. Such variations are not to be regarded as a departure from the spirit and scope of the invention, and all such modifications as would be obvious to one skilled in the art are intended to be included within the scope of the following claims.

What is claimed is:

1. A method of surface treating a polyimide film to impart improved adhesion to metal which comprises treating the surface of a polyimide film having a biphenyltetraacarboxylic acid component by contact with a solution containing at least one of potassium permanganate and sodium permanganate and at least one of potassium hydroxide and sodium hydroxide and treating said surface with an acid.

2. The method of surface treating a polyimide film according to claim 1, wherein said contact is carried out by immersing the polyimide film in an aqueous solution containing at least one of potassium permanganate and sodium permanganate in a total concentration of 10 to 100 g/l and at least one of potassium hydroxide and sodium hydroxide in a total concentration of 10 to 100 g/l at 20 to 85°C for 10 to 600 seconds.

3. The method of surface treating a polyimide film according to claim 1, which further comprises plasma treating the surface of the polyimide film after the acid treatment.

4. The method of surface treating a polyimide film according to claim 1, wherein said polyimide film has a multilayer structure composed of a highly heat-resistant polyimide layer based on a biphenyltetraacarboxylic acid component having at least one side thereof a thermoplastic polyimide layer based on a biphenyltetraacarboxylic acid component.

5. A polyimide film having a thin metal layer which comprises a polyimide film having been surface treated by the method according to any one of claims 1 to 4 to have improved adhesion to metal and a thin metal layer formed on the treated side of said polyimide film by vapor deposition or a combination of vapor deposition and plating.

6. A polyimide film having a thin metal layer according to claim 5, wherein said thin metal layer has a three-layer structure composed of a first metal layer formed on the surface-treated side of the polyimide film by vapor deposition, a second metal layer formed on said first metal layer by vapor deposition and/or plating, and an outermost layer formed on said second metal layer by plating.

7. The polyimide film having a thin metal layer according to claim 6, wherein said first metal layer is made of nickel, chromium, cobalt, palladium, molybdenum, titanium, zirconium or a nickel-copper alloy, said first metal layer has a thickness of 1 to 30 μm, said second metal layer is made of nickel, cobalt, a nickel-cobalt alloy or copper, said second metal layer has a thickness of 0.1 to 2.0 μm, and said outermost metal layer is a copper layer having a thickness of 0 to 20 μm.

8. The polyimide film having a thin metal layer according to claim 6, having peel strength of not less than 0.5 kg/cm even when allowed to stand under a heating at 150°C for 24 hrs, 200°C for 24 hrs, or 121°C for 24 hrs at 100% RH under 2 atm.
