## FIELD OF THE INVENTION

**[0003]** The present invention relates to compositions, methods and processes for the design, preparation, manufacture, use and/or formulation of AAV particles comprising modulatory polynucleotides, e.g., polynucleotides encoding small interfering RNA (siRNA) molecules which target the Huntingtin (HTT) gene (e.g., the wild-type or the mutated CAG-expanded HTT gene). Targeting of the mutated HTT gene may interfere with the HTT gene expression and the resultant HTT protein production. The AAV particles comprising modulatory polynucleotides encoding the siRNA molecules may be inserted into recombinant adeno-associated virus (AAV) vectors. Methods for using the AAV particles to inhibit the HTT gene expression in a subject with a neurodegenerative disease (e.g., Huntington's Disease (HD)) are also disclosed.

## BACKGROUND OF THE INVENTION

**[0004]** Huntington's Disease (HD) is a monogenic fatal neurodegenerative disease characterized by progressive chorea, neuropsychiatric and cognitive dysfunction. Huntington's Disease is known to be caused by an autosomal dominant triplet (CAG) repeat expansion which encodes poly-glutamine in the N-terminus of the huntingtin (HTT) protein. This repeat expansion results in a toxic gain of function of HTT and ultimately leads to striatal neurodegeneration which progresses to widespread brain atrophy. Symptoms typically appear between the ages of 35-44 and life expectancy subsequent to onset is 10-25 years. Interestingly, the length of the HTT expansion correlates with both age of onset and rate of disease progression, with longer expansions linked to greater severity of disease. In a small percentage

of the HD population (~6%), disease onset occurs from 2-20 years of age with appearance of an akinetic-rigid syndrome. These cases tend to progress faster than those of the later onset variety and have been classified as juvenile or Westphal variant HD. It is estimated that approximately 35,000-70,000 patients are currently suffering from HD in the US and Europe. Currently, only symptomatic relief and supportive therapies are available for treatment of HD, with a cure yet to be identified. Ultimately, individuals with HD succumb to other diseases (e.g., pneumonia, heart failure), choking, suffocation or other complications such as physical injury from falls.

**[0005]** The mechanisms by which CAG-expanded HTT results in neurotoxicity are not well understood. Huntingtin protein is expressed in all cells, though its concentration is highest in the brain. The normal function of HTT is unknown, but in the brains of HD patients, HTT aggregates into abnormal nuclear inclusions. It is now believed that it is this process of misfolding and aggregating along with the associated protein intermediates (i.e. the soluble species and toxic N-terminal fragments) that result in neurotoxicity.

**[0006]** Studies in animal models of HD have suggested that phenotypic reversal is feasible, for example, subsequent to gene shut off in regulated-expression models. Further, animal models in which silencing of HTT was tested, demonstrated promising results with the therapy being both well tolerated and showing potential therapeutic benefit. These findings indicate that HTT silencing may serve as a potential therapeutic target for treatment of HD.

**[0007]** The adeno-associated virus (AAV) is a member of the parvovirus family and has emerged as an attractive vector for gene therapy in large part because this virus is apparently non-pathogenic; in fact, AAV has not been associated with any human disease. Further appeal is due to its ability to transduce dividing and non-diving cells (including efficient transduction of neurons), diminished proinflammatory and immune responses in humans, its inability to autonomously replicate without a helper virus (AAV is a helper-dependent DNA parvovirus which belongs to the genus *Dependovirus*), and its long-term gene expression. Although over 10 recombinant AAV serotypes (rAAV) have been engineered into vectors, rAAV2 is the most frequently employed serotype for gene therapy trials. Additional rAAV serotypes have been developed and tested in animal models that are more efficient at neuronal transduction.

**[0008]** The present invention develops an AAV particle comprising modulatory polynucleotides encoding novel double stranded RNA (dsRNA) constructs and siRNA constructs and methods of their design, to inhibit or prevent the expression of CAG-expanded HTT in HD patients for treatment of the disease.

## DETAILED DESCRIPTION OF THE INVENTION

## I. COMPOSITIONS OF THE INVENTION

**[0042]** According to the present invention, compositions for delivering modulatory polynucleotides and/or modulatory polynucleotide-based compositions by adeno-associated viruses (AAVs) are provided. AAV particles of the invention may be provided via any of several routes of administration, to a cell, tissue, organ, or organism, *in vivo*, *ex vivo* or *in vitro*.

**[0043]** As used herein, an "AAV particle" is a virus which comprises a viral genome with at least one payload region and at least one inverted terminal repeat (ITR) region.

**[0044]** As used herein, "viral genome" or "vector genome" or "viral vector" refers to the nucleic acid sequence(s) encapsulated in an AAV particle. Viral genomes comprise at least one payload region encoding polypeptides or fragments thereof.

**[0045]** As used herein, a "payload" or "payload region" is any nucleic acid molecule which encodes one or more polypeptides of the invention. At a minimum, a payload region comprises nucleic acid sequences that encode a sense and antisense sequence, an siRNA-based composition, or a fragment thereof, but may also optionally comprise one or more functional or regulatory elements to facilitate transcriptional expression and/or polypeptide translation.

**[0046]** The nucleic acid sequences and polypeptides disclosed herein may be engineered to contain modular elements and/or sequence motifs assembled to enable expression of the modulatory polynucleotides and/or modulatory polynucleotide-based compositions of the invention. In some embodiments, the nucleic acid sequence comprising the payload region may comprise one or more of a promoter region, an intron, a Kozak sequence, an enhancer or a polyadenylation sequence. Payload regions of the invention typically encode at least one sense and antisense sequence, an siRNA-based compositions, or fragments of the foregoing in combination with each other or in combination with other polypeptide moieties.

**[0047]** The payload regions of the invention may be delivered to one or more target cells, tissues, organs or organisms within the viral genome of an AAV particle.

Adeno-associated viruses (AAVs) and AAV particles

**[0048]** Viruses of the Parvoviridae family are small non-enveloped icosahedral capsid viruses characterized by a single stranded DNA genome. Parvoviridae family viruses consist of two subfamilies: Parvovirinae, which infect vertebrates, and Densovirinae, which infect invertebrates. Due to its relatively simple structure, easily manipulated using standard molecular

biology techniques, this virus family is useful as a biological tool. The genome of the virus may be modified to contain a minimum of components for the assembly of a functional recombinant virus, or viral particle, which is loaded with or engineered to express or deliver a desired payload, which may be delivered to a target cell, tissue, organ, or organism.

**[0049]** The parvoviruses and other members of the Parvoviridae family are generally described in Kenneth I. Berns, "Parvoviridae: The Viruses and Their Replication," Chapter 69 in FIELDS VIROLOGY (3d Ed. 1996), the contents of which are incorporated by reference in their entirety.

**[0050]** The Parvoviridae family comprises the Dependovirus genus which includes adeno-associated viruses (AAV) capable of replication in vertebrate hosts including, but not limited to, human, primate, bovine, canine, equine, and ovine species.

**[0051]** The AAV viral genome is a linear, single-stranded DNA (ssDNA) molecule approximately 5,000 nucleotides (nt) in length. The AAV viral genome can comprise a payload region and at least one inverted terminal repeat (ITR) or ITR region. ITRs traditionally flank the coding nucleotide sequences for the non-structural proteins (encoded by Rep genes) and the structural proteins (encoded by capsid genes or Cap genes). While not wishing to be bound by theory, an AAV viral genome typically comprises two ITR sequences. The AAV viral genome comprises a characteristic T-shaped hairpin structure defined by the self-complementary terminal 145 nt of the 5' and 3' ends of the ssDNA which form an energetically stable double stranded region. The double stranded hairpin structures comprise multiple functions including, but not limited to, acting as an origin for DNA replication by functioning as primers for the endogenous DNA polymerase complex of the host viral replication cell.

**[0052]** In addition to the encoded heterologous payload, AAV vectors may comprise the viral genome, in whole or in part, of any naturally occurring and/or recombinant AAV serotype nucleotide sequence or variant. AAV variants may have sequences of significant homology at the nucleic acid (genome or capsid) and amino acid levels (capsids), to produce constructs which are generally physical and functional equivalents, replicate by similar mechanisms, and assemble by similar mechanisms. Chiorini et al., J. Vir. 71: 6823-33(1997); Srivastava et al., J. Vir. 45:555-64 (1983); Chiorini et al., J. Vir. 73:1309-1319 (1999); Rutledge et al., J. Vir. 72:309-319 (1998); and Wu et al., J. Vir. 74: 8635-47 (2000), the contents of each of which are incorporated herein by reference in their entirety.

**[0053]** In one embodiment, AAV particles of the present invention are recombinant AAV vectors which are replication defective, lacking sequences encoding functional Rep and Cap proteins within their viral genome. These defective AAV vectors may lack most or all parental

coding sequences and essentially carry only one or two AAV ITR sequences and the nucleic acid of interest for delivery to a cell, a tissue, an organ or an organism.

**[0054]** In one embodiment, the viral genome of the AAV particles of the present invention comprise at least one control element which provides for the replication, transcription and translation of a coding sequence encoded therein. Not all of the control elements need always be present as long as the coding sequence is capable of being replicated, transcribed and/or translated in an appropriate host cell. Non-limiting examples of expression control elements include sequences for transcription initiation and/or termination, promoter and/or enhancer sequences, efficient RNA processing signals such as splicing and polyadenylation signals, sequences that stabilize cytoplasmic mRNA, sequences that enhance translation efficacy (e.g., Kozak consensus sequence), sequences that enhance protein stability, and/or sequences that enhance protein processing and/or secretion.

**[0055]** According to the present invention, AAV particles for use in therapeutics and/or diagnostics comprise a virus that has been distilled or reduced to the minimum components necessary for transduction of a nucleic acid payload or cargo of interest. In this manner, AAV particles are engineered as vehicles for specific delivery while lacking the deleterious replication and/or integration features found in wild-type viruses.

**[0056]** AAV vectors of the present invention may be produced recombinantly and may be based on adeno-associated virus (AAV) parent or reference sequences. As used herein, a "vector" is any molecule or moiety which transports, transduces or otherwise acts as a carrier of a heterologous molecule such as the nucleic acids described herein.

**[0057]** In addition to single stranded AAV viral genomes (e.g., ssAAVs), the present invention also provides for self-complementary AAV (scAAVs) viral genomes. scAAV viral genomes contain DNA strands which anneal together to form double stranded DNA. By skipping second strand synthesis, scAAVs allow for rapid expression in the cell.

**[0058]** In one embodiment, the AAV particle of the present invention is an scAAV.

**[0059]** In one embodiment, the AAV particle of the present invention is an ssAAV.

**[0060]** Methods for producing and/or modifying AAV particles are disclosed in the art such as pseudotyped AAV vectors (PCT Patent Publication Nos. WO200028004; WO200123001; WO2004112727; WO 2005005610 and WO 2005072364, the content of each of which is incorporated herein by reference in its entirety).

**[0061]** AAV particles may be modified to enhance the efficiency of delivery. Such modified AAV particles can be packaged efficiently and be used to successfully infect the target cells at

high frequency and with minimal toxicity. In some embodiments the capsids of the AAV particles are engineered according to the methods described in US Publication Number US 20130195801, the contents of which are incorporated herein by reference in their entirety.

**[0062]** In one embodiment, the AAV particles comprising a payload region encoding the polypeptides of the invention may be introduced into mammalian cells.

*AAV serotypes*

**[0063]** AAV particles of the present invention may comprise or be derived from any natural or recombinant AAV serotype. *Viral Genome Component: Untranslated Regions (UTRs)*

**[00176]** By definition, wild type untranslated regions (UTRs) of a gene are transcribed but not translated. Generally, the 5' UTR starts at the transcription start site and ends at the start codon and the 3' UTR starts immediately following the stop codon and continues until the termination signal for transcription.

**[00177]** Features typically found in abundantly expressed genes of specific target organs may be engineered into UTRs to enhance the stability and protein production. As a non-limiting example, a 5' UTR from mRNA normally expressed in the liver (e.g., albumin, serum amyloid A, Apolipoprotein A/B/E, transferrin, alpha fetoprotein, erythropoietin, or Factor VIII) may be used in the viral genomes of the AAV particles of the invention to enhance expression in hepatic cell lines or liver.

**[00178]** While not wishing to be bound by theory, wild-type 5′ untranslated regions (UTRs) include features which play roles in translation initiation. Kozak sequences, which are commonly known to be involved in the process by which the ribosome initiates translation of many genes, are usually included in 5' UTRs. Kozak sequences have the consensus CCR(A/G)CCAUGG, where R is a purine (adenine or guanine) three bases upstream of the start codon (ATG), which is followed by another 'G'.

**[00179]** In one embodiment, the 5'UTR in the viral genome includes a Kozak sequence.

**[00180]** In one embodiment, the 5'UTR in the viral genome does not include a Kozak sequence.

**[00181]** While not wishing to be bound by theory, wild-type 3′ UTRs are known to have stretches of Adenosines and Uridines embedded therein. These AU rich signatures are particularly prevalent in genes with high rates of turnover. Based on their sequence features and functional properties, the AU rich elements (AREs) can be separated into three classes (Chen et al, 1995, the contents of which are herein incorporated by reference in its entirety): Class I AREs, such as, but not limited to, c-Myc and MyoD, contain several dispersed copies of an AUUUA motif within U-rich regions. Class II AREs, such as, but not limited to, GM-CSF and TNF-a, possess two or more overlapping UUAUUUA(U/A)(U/A) nonamers. Class III ARES, such as, but not limited to, c-Jun and Myogenin, are less well defined. These U rich regions do not contain an AUUUA motif. Most proteins binding to the AREs are known to destabilize the messenger, whereas members of the ELAV family, most notably HuR, have been documented to increase the stability of mRNA. HuR binds to AREs of all the three classes. Engineering the HuR specific binding sites into the 3′ UTR of nucleic acid molecules will lead to HuR binding and thus, stabilization of the message *in vivo*.

**[00182]** Introduction, removal or modification of 3′ UTR AU rich elements (AREs) can be used to modulate the stability of polynucleotides. When engineering specific polynucleotides, e.g., payload regions of viral genomes, one or more copies of an ARE can be introduced to make polynucleotides less stable and thereby curtail translation and decrease production of the resultant protein. Likewise, AREs can be identified and removed or mutated to increase the intracellular stability and thus increase translation and production of the resultant protein.

**[00183]** In one embodiment, the 3' UTR of the viral genome may include an oligo(dT) sequence for templated addition of a poly-A tail.

**[00184]** In one embodiment, the viral genome may include at least one miRNA seed, binding site or full sequence. microRNAs (or miRNA or miR) are 19-25 nucleotide noncoding RNAs that bind to the sites of nucleic acid targets and down-regulate gene expression either by reducing nucleic acid molecule stability or by inhibiting translation. A microRNA sequence comprises a "seed" region, i.e., a sequence in the region of positions 2-8 of the mature microRNA, which sequence has perfect Watson-Crick complementarity to the miRNA target sequence of the nucleic acid.

**[00185]** In one embodiment, the viral genome may be engineered to include, alter or remove at least one miRNA binding site, sequence or seed region.

**[00186]** Any UTR from any gene known in the art may be incorporated into the viral genome of the AAV particle. These UTRs, or portions thereof, may be placed in the same orientation as in the gene from which they were selected or they may be altered in orientation or location. In one embodiment, the UTR used in the viral genome of the AAV particle may be inverted, shortened, lengthened, made with one or more other 5′ UTRs or 3′ UTRs known in the art. As used herein, the term "altered" as it relates to a UTR, means that the UTR has been changed in some way in relation to a reference sequence. For example, a 3′ or 5′ UTR may be altered relative to a wild type or native UTR by the change in orientation or location as taught above or may be altered by the inclusion of additional nucleotides, deletion of nucleotides, swapping or transposition of nucleotides.

**[00187]** In one embodiment, the viral genome of the AAV particle comprises at least one artificial UTRs which is not a variant of a wild type UTR.

**[00188]** In one embodiment, the viral genome of the AAV particle comprises UTRs which have been selected from a family of transcripts whose proteins share a common function, structure, feature or property.

**[00280]** The payload region may be constructed in such a way as to reflect a region similar to or mirroring the natural organization of an mRNA.

**[00281]** The payload region may comprise a combination of coding and non-coding nucleic acid sequences.

**[00282]** In some embodiments, the AAV payload region may encode a coding or non-coding RNA.

**[00283]** In one embodiment, the AAV particle comprises a viral genome with a payload region comprising nucleic acid sequences encoding a siRNA, miRNA or other RNAi agent. In such an embodiment, a viral genome encoding more than one polypeptide may be replicated and packaged into a viral particle. A target cell transduced with a viral particle may express the encoded siRNA, miRNA or other RNAi agent inside a single cell.

*Modulatory Polynucleotides*

**[00284]** In one embodiment, modulatory polynucleotides, e.g., RNA or DNA molecules, may be used to treat neurodegenerative disease, in particular, Huntington's Disease (HD). As used herein, a "modulatory polynucleotide" is any nucleic acid sequence(s) which functions to modulate (either increase or decrease) the level or amount of a target gene, e.g., mRNA or protein levels.

**[00285]** In one embodiment, the modulatory polynucleotides may comprise at least one nucleic acid sequence encoding at least one siRNA molecule. The nucleic acids may, independently if there is more than one, encode 1, 2, 3, 4, 5, 6, 7, 8, 9, or more than 9 siRNA molecules.

**[00286]** In one embodiment, the molecular scaffold may be located downstream of a CMV promoter, fragment or variant thereof.

**[00287]** In one embodiment, the molecular scaffold may be located downstream of a CBA promoter, fragment or variant thereof.

**[00288]** In one embodiment, the molecular scaffold may be a natural pri-miRNA scaffold located downstream of a CMV promoter. As a non-limiting example, the natural pri-miRNA scaffold is derived from the human miR155 scaffold.

**[00289]** In one embodiment, the molecular scaffold may be a natural pri-miRNA scaffold located downstream of a CBA promoter.

**[00290]** In one embodiment, the selection of a molecular scaffold and modulatory polynucleotide is determined by a method of comparing modulatory polynucleotides in pri-miRNA (see e.g., the method described by Miniarikova et al. *Design, Characterization, and Lead Selection of Therapeutic miRNAs Targeting Huntingtin for Development of Gene Therapy for Huntington's Disease*. Molecular Therapy-Nucleic Acids (2016) 5, e297 and International Publication No. WO2016102664; the contents of each of which are herein incorporated by reference in their entireties). The modulatory polynucleotide may, but it not limited to, targeting exon 1, CAG repeats, SNP rs362331 in exon 50 and/or SNP rs362307 in exon 67. To evaluate the activities of the modulatory polynucleotides, the molecular scaffold used which may be used is a human pri-miRNA scaffold (e.g., miR155 scaffold) and the promoter may be CMV. The activity may be determined *in vitro* using HEK293T cells and a reporter (e.g., Luciferase). For exon 1 targeting, the modulatory polynucleotide is determined to be efficient at HTT knockdown if the knockdown is 80% or greater. For CAG targeting, the modulatory polynucleotide is determined to be efficient at HTT knockdown if the knockdown is at least 60%. For SNP targeting, the modulatory polynucleotide is determined to be efficient at HTT knockdown if the knockdown is at least 60%. For allele selectivity for CAG repeats or SNP targeting the

modulatory polynucleotides may comprise at least 1 substitution in order to improve allele selectivity. As a non-limiting example, substitution may be a G or C replaced with a T or corresponding U and A or T/U replaced by a C.

**[00291]** In order to evaluate the optimal molecular scaffold for the modulatory polynucleotide, the modulatory polynucleotide is used in pri-miRNA scaffolds with a CAG promoter. The constructs are co-transfected with a reporter (e.g., luciferase reporter) at 50 ng. Constructs with greater than 80% knockdown at 50 ng co-transfection are considered efficient. In one aspect, the constructs with strong guide-strand activity are preferred. The molecular scaffolds can be processed in HEK293T cells by NGS to determine guide-passenger ratios, and processing variability.

**[00292]** To evaluate the molecular scaffolds and modulatory polynucleotides *in vivo* the molecular scaffolds comprising the modulatory polynucleotides are packaged in AAV (e.g., the serotype may be AAV5 (see e.g., the method and constructs described in WO2015060722, the contents of which are herein incorporated by reference in their entirety)) and administered to an *in vivo* model (e.g., Hu128/21 HD mouse) and the guide-passenger ratios, 5' and 3' end processing, reversal of guide and passenger strands, and knockdown can be determined in different areas of the model.

**[00293]** In one embodiment, the selection of a molecular scaffold and modulatory polynucleotide is determined by a method of comparing modulatory polynucleotides in natural pri-miRNA and synthetic pri-miRNA. The modulatory polynucleotide may, but it not limited to, targeting an exon other than exon 1. To evaluate the activities of the modulatory polynucleotides, the molecular scaffold is used with a CBA promoter. In one aspect, the activity may be determined *in vitro* using HEK293T cells, HeLa cell and a reporter (e.g., Luciferase) and knockdown efficient modulatory polynucleotides showed HTT knockdown of at least 80% in the cell tested. Additionally, the modulatory polynucleotides which are considered most efficient showed low to no significant passenger strand (p-strand) activity. In another aspect, the endogenous HTT knockdown efficacy is evaluated by transfection *in vitro* using HEK293T cells, HeLa cell and a reporter. Efficient modulatory polynucleotides show greater than 50% endogenous HTT knockdown. In yet another aspect, the endogenous HTT knockdown efficacy is evaluated in different cell types (e.g., HEK293, HeLa, primary astrocytes, U251 astrocytes, SH-SY5Y neuron cells and fibroblasts from HD patients) by infection (e.g., AAV2). Efficient modulatory polynucleotides show greater than 60% endogenous HTT knockdown.

**[00294]** To evaluate the molecular scaffolds and modulatory polynucleotides *in vivo* the molecular scaffolds comprising the modulatory polynucleotides are packaged in AAV and administered to an *in vivo* model (e.g., YAC128 HD mouse) and the guide-passenger ratios, 5' and 3' end processing, ratio of guide to passenger strands, and knockdown can be determined in different areas of the model (e.g., tissue regions). The molecular scaffolds can be processed from *in vivo* samples by NGS to determine guide-passenger ratios, and processing variability.

**[00295]** In one embodiment, the modulatory polynucleotide is designed using at least one of the following properties: loop variant, seed mismatch/bulge/wobble variant, stem mismatch, loop variant and vassal stem mismatch variant, seed mismatch and basal stem mismatch variant, stem mismatch and basal stem mismatch variant, seed wobble and basal stem wobble variant, or a stem sequence variant.

*siRNA Molecules*

**[00296]** The present invention relates to RNA interference (RNAi) induced inhibition of gene expression for treating neurodegenerative disorders. Provided herein are siRNA duplexes or encoded dsRNA that target the HTT gene (referred to herein collectively as "siRNA molecules"). Such siRNA duplexes or encoded dsRNA can reduce or silence HTT gene expression in cells, for example, medium spiny neurons, cortical neurons and/or astrocytes, thereby, ameliorating symptoms of Huntington's Disease (HD).

**[00297]** RNAi (also known as post-transcriptional gene silencing (PTGS), quelling, or co-suppression) is a post-transcriptional gene silencing process in which RNA molecules, in a sequence specific manner, inhibit gene expression, typically by causing the destruction of specific mRNA molecules. The active components of RNAi are short/small double stranded RNAs (dsRNAs), called small interfering RNAs (siRNAs), that typically contain 15-30 nucleotides (e.g., 19 to 25, 19 to 24 or 19-21 nucleotides) and 2 nucleotide 3' overhangs and that match the nucleic acid sequence of the target gene. These short RNA species may be naturally produced *in vivo* by Dicer-mediated cleavage of larger dsRNAs and they are functional in mammalian cells.

**[00298]** Naturally expressed small RNA molecules, named microRNAs (miRNAs), elicit gene silencing by regulating the expression of mRNAs. The miRNAs containing RNA Induced Silencing Complex (RISC) targets mRNAs presenting a perfect sequence complementarity with nucleotides 2-7 in the 5' region of the miRNA which is called the seed region, and other base pairs with its 3' region. miRNA mediated down regulation of gene expression may be caused by cleavage of the target mRNAs, translational inhibition of the target mRNAs, or mRNA decay.

miRNA targeting sequences are usually located in the 3'-UTR of the target mRNAs. A single miRNA may target more than 100 transcripts from various genes, and one mRNA may be targeted by different miRNAs.

**[00299]** siRNA duplexes or dsRNA targeting a specific mRNA may be designed and synthesized *in vitro* and introduced into cells for activating RNAi processes. Elbashir et al. demonstrated that 21-nucleotide siRNA duplexes (termed small interfering RNAs) were capable of effecting potent and specific gene knockdown without inducing immune response in mammalian cells (Elbashir SM et al., *Nature*, 2001, 411, 494-498). Since this initial report, post-transcriptional gene silencing by siRNAs quickly emerged as a powerful tool for genetic analysis in mammalian cells and has the potential to produce novel therapeutics.

**[00300]** RNAi molecules which were designed to target against a nucleic acid sequence that encodes poly-glutamine repeat proteins which cause poly-glutamine expansion diseases such as Huntington's Disease, are described in US Patent No. 9,169,483 and 9,181,544 and International Patent Publication No. WO2015179525, the content of each of which is herein incorporated by reference in their entirety. US Patent Nos. 9,169,483 and 9,181,544 and International Patent Publication No. WO2015179525 each provide isolated RNA duplexes comprising a first strand of RNA (e.g., 15 contiguous nucleotides) and second strand of RNA (e.g., complementary to at least 12 contiguous nucleotides of the first strand) where the RNA duplex is about 15 to 30 base pairs in length. The first strand of RNA and second strand of RNA may be operably linked by an RNA loop (~4 to 50 nucleotides) to form a hairpin structure which may be inserted into an expression cassette. Non-limiting examples of loop portions include SEQ ID NO: 9-14 of US Patent No. 9,169,483, the content of which is herein incorporated by reference in its entirety. Non-limiting examples of strands of RNA which may be used, either full sequence or part of the sequence, to form RNA duplexes include SEQ ID NO: 1-8 of US Patent No. 9,169,483 and SEQ ID NO: 1-11, 33-59, 208-210, 213-215 and 218-221 of US Patent No. 9,181,544, the contents of each of which is herein incorporated by reference in its entirety. Non-limiting examples of RNAi molecules include SEQ ID NOs: 1-8 of US Patent No. 9,169,483, SEQ ID NOs: 1-11, 33-59, 208-210, 213-215 and 218-221 of US Patent No. 9,181,544 and SEQ ID NOs: 1, 6, 7, and 35-38 of International Patent Publication No. WO2015179525, the contents of each of which is herein incorporated by reference in their entirety.

**[00301]** *In vitro* synthetized siRNA molecules may be introduced into cells in order to activate RNAi. An exogenous siRNA duplex, when it is introduced into cells, similar to the endogenous dsRNAs, can be assembled to form the RNA Induced Silencing Complex (RISC), a multiunit

complex that interacts with RNA sequences that are complementary to one of the two strands of the siRNA duplex (i.e., the antisense strand). During the process, the sense strand (or passenger strand) of the siRNA is lost from the complex, while the antisense strand (or guide strand) of the siRNA is matched with its complementary RNA. In particular, the targets of siRNA containing RISC complexes are mRNAs presenting a perfect sequence complementarity. Then, siRNA mediated gene silencing occurs by cleaving, releasing and degrading the target.

**[00302]** The siRNA duplex comprised of a sense strand homologous to the target mRNA and an antisense strand that is complementary to the target mRNA offers much more advantage in terms of efficiency for target RNA destruction compared to the use of the single strand (ss)-siRNAs (e.g. antisense strand RNA or antisense oligonucleotides). In many cases, it requires higher concentration of the ss-siRNA to achieve the effective gene silencing potency of the corresponding duplex.

**[00303]** Any of the foregoing molecules may be encoded by a viral genome.

**Design and Sequences of siRNA duplexes targeting HTT gene**

**[00304]** The present invention provides small interfering RNA (siRNA) duplexes (and modulatory polynucleotides encoding them) that target HTT mRNA to interfere with HTT gene expression and/or HTT protein production.

**[00305]** The encoded siRNA duplex of the present invention contains an antisense strand and a sense strand hybridized together forming a duplex structure, wherein the antisense strand is complementary to the nucleic acid sequence of the targeted HTT gene, and wherein the sense strand is homologous to the nucleic acid sequence of the targeted HTT gene. In some aspects, the 5' end of the antisense strand has a 5' phosphate group and the 3' end of the sense strand contains a 3'hydroxyl group. In other aspects, there are none, one or 2 nucleotide overhangs at the 3'end of each strand.

**[00306]** Some guidelines for designing siRNAs have been proposed in the art. These guidelines generally recommend generating a 19-nucleotide duplexed region, symmetric 2-3 nucleotide 3'overhangs, 5'- phosphate and 3'- hydroxyl groups targeting a region in the gene to be silenced. Other rules that may govern siRNA sequence preference include, but are not limited to, (i) A/U at the 5′ end of the antisense strand; (ii) G/C at the 5′ end of the sense strand; (iii) at least five A/U residues in the 5′ terminal one-third of the antisense strand; and (iv) the absence of any GC stretch of more than 9 nucleotides in length. In accordance with such consideration, together with the specific sequence of a target gene, highly effective siRNA molecules essential for suppressing mammalian target gene expression may be readily designed.

**[00307]** According to the present invention, siRNA molecules (e.g., siRNA duplexes or encoded dsRNA) that target the HTT gene are designed. Such siRNA molecules can specifically, suppress HTT gene expression and protein production. In some aspects, the siRNA molecules are designed and used to selectively "knock out" HTT gene variants in cells, i.e., mutated HTT transcripts that are identified in patients with HD disease. In some aspects, the siRNA molecules are designed and used to selectively "knock down" HTT gene variants in cells. In other aspects, the siRNA molecules are able to inhibit or suppress both the wild type and mutated HTT gene.

**[00308]** In one embodiment, an siRNA molecule of the present invention comprises a sense strand and a complementary antisense strand in which both strands are hybridized together to form a duplex structure. The antisense strand has sufficient complementarity to the HTT mRNA sequence to direct target-specific RNAi, i.e., the siRNA molecule has a sequence sufficient to trigger the destruction of the target mRNA by the RNAi machinery or process.

**[00309]** In one embodiment, an siRNA molecule of the present invention comprises a sense strand and a complementary antisense strand in which both strands are hybridized together to form a duplex structure and where the start site of the hybridization to the HTT mRNA is between nucleotide 100 and 7000 on the HTT mRNA sequence. As a non-limiting example, the start site may be between nucleotide 100-150, 150-200, 200-250, 250-300, 300-350, 350-400, 400-450, 450-500, 500-550, 550-600, 600-650, 650-700, 700-70, 750-800, 800-850, 850-900, 900-950, 950-1000, 1000-1050, 1050-1100, 1100-1150, 1150-1200, 1200-1250, 1250-1300, 1300-1350, 1350-1400, 1400-1450, 1450-1500, 1500-1550, 1550-1600, 1600-1650, 1650-1700, 1700-1750, 1750-1800, 1800-1850, 1850-1900, 1900-1950, 1950-2000, 2000-2050, 2050-2100, 2100-2150, 2150-2200, 2200-2250, 2250-2300, 2300-2350, 2350-2400, 2400-2450, 2450-2500, 2500-2550, 2550-2600, 2600-2650, 2650-2700, 2700-2750, 2750-2800, 2800-2850, 2850-2900, 2900-2950, 2950-3000, 3000-3050, 3050-3100, 3100-3150, 3150-3200, 3200-3250, 3250-3300, 3300-3350, 3350-3400, 3400-3450, 3450-3500, 3500-3550, 3550-3600, 3600-3650, 3650-3700, 3700-3750, 3750-3800, 3800-3850, 3850-3900, 3900-3950, 3950-4000, 4000-4050, 4050-4100, 4100-4150, 4150-4200, 4200-4250, 4250-4300, 4300-4350, 4350-4400, 4400-4450, 4450-4500, 4500-4550, 4550-4600, 4600-4650, 4650-4700, 4700-4750, 4750-4800, 4800-4850, 4850-4900, 4900-4950, 4950-5000, 5000-5050, 5050-5100, 5100-5150, 5150-5200, 5200-5250, 5250-5300, 5300-5350, 5350-5400, 5400-5450, 5450-5500, 5500-5550, 5550-5600, 5600-5650, 5650-5700, 5700-5750, 5750-5800, 5800-5850, 5850-5900, 5900-5950, 5950-6000, 6000-6050, 6050-6100, 6100-6150, 6150-6200, 6200-6250, 6250-6300, 6300-6350, 6350-6400, 6400-6450, 6450-6500, 6500-6550, 6550-6600, 6600-6650, 6650-6700, 6700-6750, 6750-6800, 6800-6850, 6850-6900,

**[00317]** In one embodiment, the siRNA molecules of the present invention may comprise an antisense sequence from Table 2 and a sense sequence from Table 3, or a fragment or variant thereof. As a non-limiting example, the antisense sequence and the sense sequence have at least 30%, 40%, 50%, 60%, 70%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98% or 99% or at least 20-30%, 20-40%, 20-50%, 20-60%, 20-70%, 20-80%, 20-90%, 20-95%, 20-99%, 30-40%, 30-50%, 30-60%, 30-70%, 30-80%, 30-90%, 30-95%, 30-99%, 40-50%, 40-60%, 40-70%, 40-80%, 40-90%, 40-95%, 40-99%, 50-60%, 50-70%, 50-80%, 50-90%, 50-95%, 50-99%, 60-70%, 60-80%, 60-90%, 60-95%, 60-99%, 70-80%, 70-90%, 70-95%, 70-99%, 80-90%, 80-95%, 80-99%, 90-95%, 90-99% or 95-99% complementarity.

**[00318]** In one embodiment, the siRNA molecules of the present invention may comprise the sense and antisense siRNA duplex as described in Tables 4-6. As a non-limiting example, these siRNA duplexes may be tested for *in vitro* inhibitory activity on endogenous HTT gene expression. The start site for the sense and antisense sequence is compared to HTT gene sequence known as NM_002111.7 (SEQ ID NO: 1425) from NCBI.

**[00319]** In other embodiments, the siRNA molecules of the present invention can be encoded in plasmid vectors, AAV particles, viral genome or other nucleic acid expression vectors for delivery to a cell.

**[00320]** DNA expression plasmids can be used to stably express the siRNA duplexes or dsRNA of the present invention in cells and achieve long-term inhibition of the target gene expression. In one aspect, the sense and antisense strands of a siRNA duplex are typically linked by a short spacer sequence leading to the expression of a stem-loop structure termed short hairpin RNA (shRNA). The hairpin is recognized and cleaved by Dicer, thus generating mature siRNA molecules.

**[00321]** According to the present invention, AAV particles comprising the nucleic acids encoding the siRNA molecules targeting HTT mRNA are produced, the AAV serotypes may be

any of the serotypes listed in Table 1. Non-limiting examples of the AAV serotypes include, AAV1, AAV2, AAV3, AAV4, AAV5, AAV6, AAV7, AAV8, AAV9, AAV9.47, AAV9(hu14), AAV10, AAV11, AAV12, AAVrh8, AAVrh10, AAV-DJ8, AAV-DJ, AAV-PHP.A, and/or AAV-PHP.B, and variants thereof.

**[00322]** In some embodiments, the siRNA duplexes or encoded dsRNA of the present invention suppress (or degrade) target mRNA (e.g., HTT). Accordingly, the siRNA duplexes or encoded dsRNA can be used to substantially inhibit HTT gene expression in a cell, for example a neuron. In some aspects, the inhibition of HTT gene expression refers to an inhibition by at least about 20%, preferably by at least about 30%, 40%, 50%, 60%, 70%, 80%, 85%, 90%, 95% and 100%, or at least 20-30%, 20-40%, 20-50%, 20-60%, 20-70%, 20-80%, 20-90%, 20-95%, 20-100%, 30-40%, 30-50%, 30-60%, 30-70%, 30-80%, 30-90%, 30-95%, 30-100%, 40-50%, 40-60%, 40-70%, 40-80%, 40-90%, 40-95%, 40-100%, 50-60%, 50-70%, 50-80%, 50-90%, 50-95%, 50-100%, 60-70%, 60-80%, 60-90%, 60-95%, 60-100%, 70-80%, 70-90%, 70-95%, 70-100%, 80-90%, 80-95%, 80-100%, 90-95%, 90-100% or 95-100%. Accordingly, the protein product of the targeted gene may be inhibited by at least about 20%, preferably by at least about 30%, 40%, 50%, 60%, 70%, 80%, 85%, 90%, 95% and 100%, or at least 20-30%, 20-40%, 20-50%, 20-60%, 20-70%, 20-80%, 20-90%, 20-95%, 20-100%, 30-40%, 30-50%, 30-60%, 30-70%, 30-80%, 30-90%, 30-95%, 30-100%, 40-50%, 40-60%, 40-70%, 40-80%, 40-90%, 40-95%, 40-100%, 50-60%, 50-70%, 50-80%, 50-90%, 50-95%, 50-100%, 60-70%, 60-80%, 60-90%, 60-95%, 60-100%, 70-80%, 70-90%, 70-95%, 70-100%, 80-90%, 80-95%, 80-100%, 90-95%, 90-100% or 95-100%.

**siRNA modification**

**[00359]** In some embodiments, the siRNA molecules of the present invention, when not delivered as a precursor or DNA, may be chemically modified to modulate some features of RNA molecules, such as, but not limited to, increasing the stability of siRNAs *in vivo*. The chemically modified siRNA molecules can be used in human therapeutic applications, and are improved without compromising the RNAi activity of the siRNA molecules. As a non-limiting example, the siRNA molecules modified at both the 3′ and the 5′ end of both the sense strand and the antisense strand.

**[00360]** In some aspects, the siRNA duplexes of the present invention may contain one or more modified nucleotides such as, but not limited to, sugar modified nucleotides, nucleobase modifications and/or backbone modifications. In some aspects, the siRNA molecule may contain combined modifications, for example, combined nucleobase and backbone modifications.

**[00361]** In one embodiment, the modified nucleotide may be a sugar-modified nucleotide. Sugar modified nucleotides include, but are not limited to 2′-fluoro, 2′-amino and 2′-thio modified ribonucleotides, e.g. 2′-fluoro modified ribonucleotides. Modified nucleotides may be modified on the sugar moiety, as well as nucleotides having sugars or analogs thereof that are not ribosyl. For example, the sugar moieties may be, or be based on, mannoses, arabinoses, glucopyranoses, galactopyranoses, 4′-thioribose, and other sugars, heterocycles, or carbocycles.

**[00362]** In one embodiment, the modified nucleotide may be a nucleobase-modified nucleotide.

**[00363]** In one embodiment, the modified nucleotide may be a backbone-modified nucleotide. In some embodiments, the siRNA duplexes of the present invention may further comprise other modifications on the backbone. A normal “backbone”, as used herein, refers to the repeating alternating sugar-phosphate sequences in a DNA or RNA molecule. The deoxyribose/ribose sugars are joined at both the 3'-hydroxyl and 5'-hydroxyl groups to phosphate groups in ester links, also known as "phosphodiester" bonds/linker (PO linkage). The PO backbones may be modified as “phosphorothioate backbone (PS linkage). In some cases, the natural phosphodiester bonds may be replaced by amide bonds but the four atoms between two sugar units are kept. Such amide modifications can facilitate the solid phase synthesis of oligonucleotides and increase the thermodynamic stability of a duplex formed with siRNA complement. See e.g. Mesmaeker et al., *Pure & Appl. Chem.*, 1997, 3, 437-440; the content of which is incorporated herein by reference in its entirety.

**[00364]** Modified bases refer to nucleotide bases such as, for example, adenine, guanine, cytosine, thymine, uracil, xanthine, inosine, and queuosine that have been modified by the replacement or addition of one or more atoms or groups. Some examples of modifications on the

nucleobase moieties include, but are not limited to, alkylated, halogenated, thiolated, aminated, amidated, or acetylated bases, individually or in combination. More specific examples include, for example, 5-propynyluridine, 5-propynylcytidine, 6-methyladenine, 6-methylguanine, N,N,-dimethyladenine, 2-propyladenine, 2-propylguanine, 2-aminoadenine, 1-methylinosine, 3-methyluridine, 5-methylcytidine, 5-methyluridine and other nucleotides having a modification at the 5 position, 5-(2-amino)propyl uridine, 5-halocytidine, 5-halouridine, 4-acetylcytidine, 1-methyladenosine, 2-methyladenosine, 3-methylcytidine, 6-methyluridine, 2-methylguanosine, 7-methylguanosine, 2,2-dimethylguanosine, 5-methylaminoethyluridine, 5-methyloxyuridine, deazanucleotides such as 7-deaza-adenosine, 6-azouridine, 6-azocytidine, 6-azothymidine, 5-methyl-2-thiouridine, other thio bases such as 2-thiouridine and 4-thiouridine and 2-thiocytidine, dihydrouridine, pseudouridine, queuosine, archaeosine, naphthyl and substituted naphthyl groups, any O- and N-alkylated purines and pyrimidines such as N6-methyladenosine, 5-methylcarbonylmethyluridine, uridine 5-oxyacetic acid, pyridine-4-one, pyridine-2-one, phenyl and modified phenyl groups such as aminophenol or 2,4,6-trimethoxy benzene, modified cytosines that act as G-clamp nucleotides, 8-substituted adenines and guanines, 5-substituted uracils and thymines, azapyrimidines, carboxyhydroxyalkyl nucleotides, carboxyalkylaminoalkyl nucleotides, and alkylcarbonylalkylated nucleotides.

**[00365]** In one embodiment, the modified nucleotides may be on just the sense strand.

**[00366]** In another embodiment, the modified nucleotides may be on just the antisense strand.

**[00367]** In some embodiments, the modified nucleotides may be in both the sense and antisense strands.

**[00368]** In some embodiments, the chemically modified nucleotide does not affect the ability of the antisense strand to pair with the target mRNA sequence, such as the HTT mRNA sequence.

**[00369]** In one embodiment, the AAV particle comprising a nucleic acid sequence encoding the siRNA molecules of the present invention may encode siRNA molecules which are polycistronic molecules. The siRNA molecules may additionally comprise one or more linkers between regions of the siRNA molecules.

The molecular scaffold may comprise a 5' flanking sequence which may be of any length and may be derived in whole or in part from wild type microRNA sequence or be completely artificial. The 3' flanking sequence may mirror the 5' flanking sequence and/or a 3' flanking sequence in size and origin. Either flanking sequence may be absent. The 3' flanking sequence may optionally contain one or more CNNC motifs, where "N" represents any nucleotide.

**[00381]** Neither the identity of the sense sequence nor the homology of the antisense sequence need to be 100% complementarity to the target sequence.

**[00382]** In one embodiment, separating the sense and antisense sequence of the stem loop structure of the modulatory polynucleotide is a loop sequence (also known as a loop motif, linker or linker motif). The loop sequence may be of any length, between 4-30 nucleotides, between 4-20 nucleotides, between 4-15 nucleotides, between 5-15 nucleotides, between 6-12 nucleotides, 6 nucleotides, 7 nucleotides, 8 nucleotides, 9 nucleotides, 10 nucleotides, 11 nucleotides, 12 nucleotides, 13 nucleotides, 14 nucleotides, and/or 15 nucleotides.

**[00383]** In some embodiments, the loop sequence comprises a nucleic acid sequence encoding at least one UGUG motif. In some embodiments, the nucleic acid sequence encoding the UGUG motif is located at the 5' terminus of the loop sequence.

**[00384]** In one embodiment, spacer regions may be present in the modulatory polynucleotide to separate one or more modules (e.g., 5' flanking region, loop motif region, 3' flanking region, sense sequence, antisense sequence) from one another. There may be one or more such spacer regions present.

**[00385]** In one embodiment, a spacer region of between 8-20, i.e., 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, or 20 nucleotides may be present between the sense sequence and a flanking region sequence.

**[00386]** In one embodiment, the length of the spacer region is 13 nucleotides and is located between the 5' terminus of the sense sequence and the 3' terminus of the flanking sequence. In one embodiment, a spacer is of sufficient length to form approximately one helical turn of the sequence.

In one embodiment, a spacer is of sufficient length to form approximately one helical turn of the sequence.

**[00389]** In one embodiment, the molecular scaffold of the modulatory polynucleotide comprises in the 5' to 3' direction, a 5' flanking sequence, a 5' arm, a loop motif, a 3' arm and a 3' flanking sequence. In another non-limiting example, the 5' arm comprises a nucleic acid sequence encoding the antisense sequence and the 3' arm comprises a nucleic acid sequence encoding the sense sequence.

**[00390]** In one embodiment, the 5' arm, sense and/or antisense sequence, loop motif and/or 3' arm sequence may be altered (e.g., substituting 1 or more nucleotides, adding nucleotides and/or deleting nucleotides). The alteration may cause a beneficial change in the function of the construct (e.g., increase knock-down of the target sequence, reduce degradation of the construct, reduce off target effect, increase efficiency of the payload, and reduce degradation of the payload).

**[00391]** In one embodiment, the molecular scaffold of the modulatory polynucleotides is aligned in order to have the rate of excision of the guide strand (also referred to herein as the antisense strand) be greater than the rate of excision of the passenger strand (also referred to herein as the sense strand). The rate of excision of the guide or passenger strand may be, independently, 1%, 2%, 3%, 4%, 5%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, 99% or more than 99%. The excision of the guide strand may be 2, 3, 4, 5, 6, 7, 8, 9, 10 or more than 10 times more efficient than the excision of the passenger strand from the molecular scaffold.

**[00395]** In one embodiment, the molecular scaffold comprises a dual-function targeting modulatory polynucleotide. As used herein, a "dual-function targeting" modulatory polynucleotide is a polynucleotide where both the guide and passenger strands knock down the same target or the guide and passenger strands knock down different targets.

**[00396]** In one embodiment, the molecular scaffold of the modulatory polynucleotides described herein may comprise a 5' flanking region, a loop motif region and a 3' flanking region. *Modulatory Polynucleotide Comprising Molecular Scaffold and siRNA Molecule*

**[00481]** In one embodiment, the modulatory polynucleotide may comprise 5' and 3' flanking regions, loop motif region, and nucleic acid sequences encoding sense sequence and antisense sequence as described in Tables 10 and 11. In Tables 10 and 11, the DNA sequence identifier for the passenger and guide strands are described as well as the 5' and 3' Flanking Regions and the Loop region (also referred to as the linker region). In Tables 10 and 11, the "miR" component of the name of the sequence does not necessarily correspond to the sequence numbering of miRNA genes (e.g., VOYHTmiR-102 is the name of the sequence and does not necessarily mean that miR-102 is part of the sequence).

Transfection of separate viral replication cell populations produces two baculoviruses, one that comprises the viral construct expression vector, and another that comprises the AAV payload construct expression vector. The two baculoviruses may be used to infect a single viral replication cell population for production of AAV particles.

**[00624]** Baculovirus expression vectors for producing viral particles in insect cells, including but not limited to *Spodoptera frugiperda* (Sf9) cells, provide high titers of viral particle product. Recombinant baculovirus encoding the viral construct expression vector and AAV payload construct expression vector initiates a productive infection of viral replicating cells. Infectious baculovirus particles released from the primary infection secondarily infect additional cells in the culture, exponentially infecting the entire cell culture population in a number of infection cycles that is a function of the initial multiplicity of infection, *see* Urabe, M. *et al.*, J Virol. 2006 Feb; 80 (4):1874-85, the contents of which are herein incorporated by reference in their entirety.

**[00625]** Production of AAV particles with baculovirus in an insect cell system may address known baculovirus genetic and physical instability. In one embodiment, the production system

addresses baculovirus instability over multiple passages by utilizing a titerless infected-cells preservation and scale-up system. Small scale seed cultures of viral producing cells are transfected with viral expression constructs encoding the structural, non-structural, components of the viral particle. Baculovirus-infected viral producing cells are harvested into aliquots that may be cryopreserved in liquid nitrogen; the aliquots retain viability and infectivity for infection of large scale viral producing cell culture Wasilko DJ *et al.*, Protein Expr Purif. 2009 Jun; 65(2):122-32, the contents of which are herein incorporated by reference in their entirety.

**[00626]** A genetically stable baculovirus may be used to produce source of the one or more of the components for producing AAV particles in invertebrate cells. In one embodiment, defective baculovirus expression vectors may be maintained episomally in insect cells. In such an embodiment the bacmid vector is engineered with replication control elements, including but not limited to promoters, enhancers, and/or cell-cycle regulated replication elements.

**[00627]** In one embodiment, baculoviruses may be engineered with a (non-) selectable marker for recombination into the chitinase/cathepsin locus. The chia/v-cath locus is non-essential for propagating baculovirus in tissue culture, and the V-cath (EC 3.4.22.50) is a cysteine endoprotease that is most active on Arg-Arg dipeptide containing substrates. The Arg-Arg dipeptide is present in densovirus and parvovirus capsid structural proteins but infrequently occurs in dependovirus VP1.

**[00628]** In one embodiment, stable viral replication cells permissive for baculovirus infection are engineered with at least one stable integrated copy of any of the elements necessary for AAV replication and viral particle production including, but not limited to, the entire AAV genome, Rep and Cap genes, Rep genes, Cap genes, each Rep protein as a separate transcription cassette, each VP protein as a separate transcription cassette, the AAP (assembly activation protein), or at least one of the baculovirus helper genes with native or non-native promoters.

According to some embodiments, lysis conditions comprise changes in

temperature to promote cellular disruption. Cell lysis carried out according to such embodiments may include freeze-thaw lysis. Cell solutions may then be pumped into an interaction chamber via a pump (*e.g.* high-pressure pump) at high speed and/or pressure to produce shear fluid forces. Resulting lysates may then be collected in one or more output reservoir. Pump speed and/or pressure may be adjusted to modulate cell lysis and enhance recovery of products (*e.g.* viral particles.) Other mechanical lysis methods may include physical disruption of cells by scraping.

**[00643]** Cell lysis methods may be selected based on the cell culture format of cells to be lysed. For example, with adherent cell cultures, some chemical and mechanical lysis methods may be used. Such mechanical lysis methods may include freeze-thaw lysis or scraping. In another example, chemical lysis of adherent cell cultures may be carried out through incubation with lysis solutions comprising surfactant, such as Triton-X-100. In some cases, cell lysates generated from adherent cell cultures may be treated with one more nuclease to lower the viscosity of the lysates caused by liberated DNA.

**[00644]** In one embodiment, a method for harvesting AAV particles without lysis may be used for efficient and scalable AAV particle production. In a non-limiting example, AAV particles may be produced by culturing an AAV particle lacking a heparin binding site, thereby allowing the AAV particle to pass into the supernatant, in a cell culture, collecting supernatant from the culture; and isolating the AAV particle from the supernatant, as described in US Patent Application 20090275107, the contents of which are incorporated herein by reference in their entirety.

*Clarification*

**[00645]** Cell lysates comprising viral particles may be subjected to clarification. Clarification refers to initial steps taken in purification of viral particles from cell lysates. Clarification serves to prepare lysates for further purification by removing larger, insoluble debris. Clarification steps may include, but are not limited to centrifugation and filtration. During clarification, centrifugation may be carried out at low speeds to remove larger debris only. Similarly, filtration may be carried out using filters with larger pore sizes so that only larger debris is removed. In some cases, tangential flow filtration may be used during clarification. Objectives of viral clarification include high throughput processing of cell lysates and to optimize ultimate viral recovery. Advantages of including a clarification step include scalability for processing of larger volumes of lysate. In some embodiments, clarification may be carried out according to any of the methods presented in US Patent Nos. 8,524,446, 5,756,283, 6,258,595, 6,261,551, 6,270,996, 6,281,010, 6,365,394, 6,475,769, 6,482,634, 6,485,966, 6,943,019, 6,953,690, 7,022,519, 7,238,526, 7,291,498, 7,491,508, US Publication Nos. **[00651]** In some embodiments, ion exchange chromatography may be used to isolate viral particles. Ion exchange chromatography is used to bind viral particles based on charge-charge interactions between capsid proteins and charged sites present on a stationary phase, typically a column through which viral preparations (*e.g.* clarified lysates) are passed. After application of viral preparations, bound viral particles may then be eluted by applying an elution solution to disrupt the charge-charge interactions. Elution solutions may be optimized by adjusting salt concentration and/or pH to enhance recovery of bound viral particles. Depending on the charge of viral capsids being isolated, cation or anion exchange chromatography methods may be selected. Methods of ion exchange chromatography may include, but are not limited to any of those taught in US Patent Nos. 7,419,817, 6,143,548, 7,094,604, 6,593,123, 7,015,026 and 8,137,948, the contents of each of which are herein incorporated by reference in their entirety.

**[00652]** In some embodiments, immunoaffinity chromatography may be used. Immunoaffinity chromatography is a form of chromatography that utilizes one or more immune compounds (*e.g.* antibodies or antibody-related structures) to retain viral particles. Immune compounds may bind

specifically to one or more structures on viral particle surfaces, including, but not limited to one or more viral coat protein. In some cases, immune compounds may be specific for a particular viral variant. In some cases, immune compounds may bind to multiple viral variants. In some embodiments, immune compounds may include recombinant single-chain antibodies. Such recombinant single chain antibodies may include those described in Smith, R.H. *et al.*, 2009. Mol. Ther. 17(11):1888-96, the contents of which are herein incorporated by reference in their entirety. The method of delivering the AAV polynucleotide or AAV genome to a cell or tissue can be accomplished *in vitro, ex vivo*, or *in vivo*.

*Introduction into cells- Synthetic dsRNA*

In some embodiments, the cells may include, but are not limited to, cells of mammalian origin, cells of human origins, embryonic stem cells, induced pluripotent stem cells, neural stem cells, and neural progenitor cells.

**[00688]** Nucleic acids, including siRNA, carry a net negative charge on the sugar-phosphate backbone under normal physiological conditions. In order to enter the cell, a siRNA molecule must come into contact with a lipid bilayer of the cell membrane, whose head groups are also negatively charged.

Also, some synthetic AAV particles possess an ability to integrate the shRNA into the cell genome, thereby leading to stable siRNA expression and long-term knockdown of a target gene. In this manner, AAV particles are engineered as vehicles for specific delivery while lacking the deleterious replication and/or integration features found in wild-type virus.

**[00691]** In some embodiments, the siRNA molecules of the present invention are introduced into a cell by contacting the cell with an AAV particle comprising a modulatory polynucleotide sequence encoding a siRNA molecule, and a lipophilic carrier. The infusion rate may be changed depending on the subject, distribution, formulation or another delivery parameter.

**[00725]** In one embodiment, the AAV particle described herein is administered via putamen and caudate infusion. As a non-limiting example, the dual infusion provides a broad striatal distribution as well as a frontal and temporal cortical distribution.

**[00726]** In one embodiment, the AAV particle is AAV-DJ8 which is administered via unilateral putamen infusion. As a non-limiting example, the distribution of the administered AAV-DJ8 is similar to the distribution of AAV1 delivered via unilateral putamen infusion.

**[00727]** In one embodiment, the AAV particle described herein is administered via intrathecal (IT) infusion at C1. The infusion may be for 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 or more than 15 hours.

**[00728]** In one embodiment, the selection of subjects for administration of the AAV particle described herein and/or the effectiveness of the dose, route of administration and/or volume of administration may be evaluated using imaging of the perivascular spaces (PVS) which are also known as Virchow-Robin spaces. PVS surround the arterioles and venules as they perforate brain parenchyma and are filled with cerebrospinal fluid (CSF)/interstitial fluid. PVS are common in the midbrain, basal ganglia, and centrum semiovale. While not wishing to be bound by theory, PVS may play a role in the normal clearance of metabolites and have been associated with worse cognition and several disease states including Parkinson's disease. PVS are usually are normal in size but they can increase in size in a number of disease states. Potter et al. (Cerebrovasc Dis. 2015 Jan; 39(4): 224–231; the contents of which are herein incorporated by reference in its entirety) developed a grading method where they studied a full range of PVS and rated basal ganglia, centrum semiovale and midbrain PVS. They used the frequency and range of PVS used by Mac and Lullich et al. (J Neurol Neurosurg Psychiatry. 2004 Nov;75(11):1519-23; the contents of which are herein incorporated by reference in its entirety) and Potter et al. gave 5 ratings to basal ganglia and centrum semiovale PVS: 0 (none), 1 (1-10), 2 (11-20), 3 (21-40) and 4 (>40) and 2 ratings to midbrain PVS: 0 (non visible) or 1 (visible). The user guide for the rating system by Potter et al. can be found at: www.sbirc.ed.ac.uk/documents/epvs-rating-scale-user-guide.pdf.

**[00738]** In certain embodiments, the desired siRNA duplex dosage may be delivered using multiple administrations (*e.g.*, two, three, four, five, six, seven, eight, nine, ten, eleven, twelve, thirteen, fourteen, or more administrations). When multiple administrations are employed, split dosing regimens such as those described herein may be used. As used herein, a "split dose" is the division of single unit dose or total daily dose into two or more doses, e.g., two or more administrations of the single unit dose. As used herein, a "single unit dose" is a dose of any modulatory polynucleotide therapeutic administered in one dose/at one time/single route/single point of contact, i.e., single administration event. As used herein, a "total daily dose" is an amount given or prescribed in a 24 hour period. It may be administered as a single unit dose. In one embodiment, the AAV particles comprising the modulatory polynucleotides of the present invention are administered to a subject in split doses. They may be formulated in buffer only or in a formulation described herein.

**[00739]** In one embodiment, the dose, concentration and/or volume of the composition described herein may be adjusted depending on the contribution of the caudate or putamen to cortical and subcortical distribution after administration. The administration may be

intracerebroventricular, intraputamenal, intrathalamic, intraparenchymal, subpial, and/or intrathecal administration.

**[00740]** In one embodiment, the dose, concentration and/or volume of the composition described herein may be adjusted depending on the cortical and neuraxial distribution following administration by intracerebroventricular, intraputamenal, intrathalamic, intraparenchymal, subpial, and/or intrathecal delivery.

## IV. METHODS AND USES OF THE COMPOSITIONS OF THE INVENTION

Huntington's Disease (HD)

**[00741]** Huntington's Disease (HD) is a monogenic fatal neurodegenerative disease characterized by progressive chorea, neuropsychiatric and cognitive dysfunction. Huntington's disease is known to be caused by an autosomal dominant triplet (CAG) repeat expansion in the huntingtin (HTT) gene, which encodes poly-glutamine at the N-terminus of the HTT protein. This repeat expansion results in a toxic gain of function of HTT and ultimately leads to striatal neurodegeneration which progresses to widespread brain atrophy. Medium spiny neurons of the striatum appear to be especially vulnerable in HD with up to 95% loss, whereas interneurons are largely spared.

**[00742]** Huntington's Disease has a profound impact on quality of life. Symptoms typically appear between the ages of 35-44 and life expectancy subsequent to onset is 10-25 years. In a small percentage of the HD population (~6%), disease onset occurs prior to the age of 21 with appearance of an akinetic-rigid syndrome. These cases tend to progress faster than those of the later onset variety and have been classified as juvenile or Westphal variant HD. It is estimated that approximately 35,000-70,000 patients are currently suffering from HD in the US and Europe. Currently, only symptomatic relief and supportive therapies are available for treatment of HD, with a cure yet to be identified. Ultimately, individuals with HD succumb to pneumonia, heart failure or other complications such as physical injury from falls.

**[00743]** While not wishing to be bound by theory, the function of the wild type HTT protein may serve as a scaffold to coordinate complexes of other proteins. HTT is a very large protein (67 exons, 3144 amino acids, ~350kDa) that undergoes extensive post-translational modification and has numerous sites for interaction with other proteins, particularly at its N-terminus (coincidently the region that carries the repeats in HD). HTT localizes primarily to the cytoplasm but has been shown to shuttle into the nucleus where it may regulate gene transcription. It has also been suggested that HTT has a role in vesicular transport and regulating RNA trafficking.

**[00744]** As a non-limiting example, the HTT protein sequence is SEQ ID NO: 1424 (NCBI NP_002102.4) and the HTT nucleic acid sequence is SEQ ID NO: 1425 (NCBI NM_002111.7).

**[00745]** The mechanisms by which CAG-expanded HTT disrupts normal HTT function and results in neurotoxicity were initially thought to be a disease of haploinsufficiency, this theory was disproven when terminal deletion of the HTT gene in man did not lead to development of HD, suggesting that fully expressed HTT protein is not critical to survival. However, conditional knockout of HTT in mouse led to neurodegeneration, indicating that some amount of HTT is necessary for cell survival. Huntingtin protein is expressed in all cells, though its concentration is highest in the brain where large aggregates of abnormal HTT are found in neuronal nuclei. In the brains of HD patients, HTT aggregates into abnormal nuclear inclusions. It is now believed that it is this process of misfolding and aggregating along with the associated protein intermediates (i.e. the soluble species and toxic N-terminal fragments) that result in neurotoxicity. In fact, HD belongs to a family of nine additional human genetic disorders all of which are characterized by CAG-expanded genes and resultant polyglutamine (poly-Q) protein products with subsequent formation of intraneuronal aggregates. Interestingly, in all of these diseases the length of the expansion correlates with both age of onset and rate of disease progression, with longer expansions linked to greater severity of disease.

**[00746]** Hypotheses on the molecular mechanisms underlying the neurotoxicity of CAG-expanded HTT and its resultant aggregates have been wide ranging, but include, caspase activation, dysregulation of transcriptional pathways, increased production of reactive oxygen species, mitochondrial dysfunction, disrupted axonal transport and/or inhibition of protein degradation systems within the cell. CAG-expanded HTT may not only have a toxic gain of function, but also exert a dominant negative effect by interfering with the normal function of other cellular proteins and processes. HTT has also been implicated in non-cell autonomous neurotoxicity, whereby a cell hosting HTT spreads the HTT to other neurons nearby.

**[00747]** In one embodiment, a subject has fully penetrant HD where the HTT gene has 41 or more CAG repeats (e.g., 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90 or more than 90 CAG repeats).

**[00748]** In one embodiment, a subject has incomplete penetrance where the HTT gene has between 36 and 40 CAG repeats (e.g., 36, 37, 38, 39 and 40 CAG repeats).

**[00749]** Symptoms of HD may include features attributed to CNS degeneration such as, but are not limited to, chorea, dystonia, bradykinesia, incoordination, irritability and depression,

problem solving difficulties, reduction in the ability of a person to function in their normal day to day life, diminished speech, and difficulty swallowing, , as well as features not attributed to CNS degeneration such as, but not limited to, weight loss, muscle wasting, metabolic dysfunction and endocrine disturbances.

**[00750]** Model systems for studying Huntington's Disease which may be used with the modulatory polynucleotides and AAV particles described herein include, but are not limited to, cell models (e.g., primary neurons and induced pluripotent stem cells), invertebrate models (e.g., *drosophila* or *caenorhabditis elegans*), mouse models (e.g., YAC128 mouse model; R6/2 mouse model; BAC, YAC and knock-in mouse model), rat models (e.g., BAC) and large mammal models (e.g., pigs, sheep or monkeys).

**[00751]** Studies in animal models of HD have suggested that phenotypic reversal is feasible, for example, subsequent to gene shut off in regulated-expression models. In a mouse model allowing shut off of expression of a 94-polyglutamine repeat HTT protein, not only was the clinical syndrome reversed but also the intracellular aggregates were resolved. Further, animal models in which silencing of HTT was tested, demonstrated promising results with the therapy being both well tolerated and showing potential therapeutic benefit.

**[00752]** Such siRNA mediated HTT expression inhibition may be used for treating HD. According to the present invention, methods for treating and/or ameliorating HD in a patient comprises administering to the patient an effective amount of AAV particles comprising a nucleic acid sequence encoding the siRNA molecules of the present invention into cells. The administration of the AAV particles comprising such a nucleic acid sequence will encode the siRNA molecules which cause the inhibition/silence of HTT gene expression.

**[00753]** In one embodiment, the AAV particles described herein may be used to reduce the amount of HTT in a subject in need thereof and thus provides a therapeutic benefit as described herein.

**[00754]** In certain aspects, the symptoms of HD include behavioral difficulties and symptoms such as, but not limited to, apathy or lack of initiative, dysphoria, irritability, agitation or anxiety, poor self-care, poor judgment, inflexibility, disinhibition, depression, suicidal ideation euphoria, aggression, delusions, compulsions, hypersexuality, hallucinations, speech deterioration, slurred speech, difficulty swallowing, weight loss, cognitive dysfunction which impairs executive functions (e.g., organizing, planning, checking or adapting alternatives, and delays in the acquisition of new motor skills), unsteady gait and involuntary movements (chorea). In other aspects, the composition of the present invention is applied to one or both of the brain and the

spinal cord. In one embodiment, the survival of the subject is prolonged by treating any of the symptoms of HD described herein.

*Methods of treatment of Huntington's Disease*

**[00756]** The present invention provides AAV particles comprising modulatory polynucleotides encoding siRNA molecules targeting the HTT gene, and methods for their design and manufacture. While not wishing to be bound by a single theory of operability, the invention provides modulatory polynucleotides, including siRNAs, that interfere with HTT expression, including HTT mutant and/or wild-type HTT gene expression. Particularly, the present invention employs viral genomes such as adeno-associated viral (AAV) viral genomes comprising modulatory polynucleotide sequences encoding the siRNA molecules of the present invention. The AAV vectors comprising the modulatory polynucleotides encoding the siRNA molecules of the present invention may increase the delivery of active agents into neurons of interest such as medium spiny neurons of the striatum and cortical neurons. The siRNA duplexes or encoded dsRNA targeting the HTT gene may be able to inhibit HTT gene expression (e.g., mRNA level) significantly inside cells; therefore, reducing HTT expression induced stress inside the cells such as aggregation of protein and formation of inclusions, increased free radicals, mitochondrial dysfunction and RNA metabolism.

**[00757]** Provided in the present invention are methods for introducing the AAV particles comprising a modulatory polynucleotide sequence encoding the siRNA molecules of the present invention into cells, the method comprising introducing into said cells any of the AAV particles in an amount sufficient for degradation of target HTT mRNA to occur, thereby activating target-specific RNAi in the cells. In some aspects, the cells may be stem cells, neurons such as medium spiny or cortical neurons, muscle cells and glial cells such as astrocytes.

**[00758]** In some embodiments, the present invention provides methods for treating or ameliorating Huntington's Disease (HD) by administering to a subject in need thereof a therapeutically effective amount of a plasmid or AAV vector described herein.

**[00759]** In some embodiments, the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be used to treat and/or ameliorate for HD.

**[00760]** In one embodiment, the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be used to reduce the cognitive and/or motor decline of a subject with HD, where the amount of decline is determined by a standard evaluation system such as, but not limited to, Unified Huntington's Disease Ratings Scale (UHDRS) and subscores, and cognitive testing.

**[00761]** In one embodiment, the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be used to reduce the decline of functional capacity and activities of daily living as measured by a standard evaluation system such as, but not limited to, the total functional capacity (TFC) scale.

**[00762]** In some embodiments, the present invention provides methods for treating, or ameliorating Huntington's Disease associated with HTT gene and/or HTT protein in a subject in need of treatment, the method comprising administering to the subject a pharmaceutically effective amount of AAV particles comprising modulatory polynucleotides encoding at least one siRNA duplex targeting the HTT gene, inhibiting HTT gene expression and protein production, and ameliorating symptoms of HD in the subject.

**[00763]** In one embodiment, the AAV vectors of the present invention may be used as a method of treating Huntington's disease in a subject in need of treatment. Any method known in the art for defining a subject in need of treatment may be used to identify said subject(s). A subject may have a clinical diagnosis of Huntington's disease, or may be pre-symptomatic. Any known method for diagnosing HD may be utilized, including, but not limited to, cognitive assessments and/or neurological or neuropsychiatric examinations, motor tests, sensory tests, psychiatric evaluations, brain imaging, family history and/or genetic testing.

**[00764]** In one embodiment, HD subject selection is determined with the use of the Prognostic Index for Huntington's Disease, or a derivative thereof (Long JD et al., *Movement Disorders,* 2017, 32(2), 256-263, the contents of which are herein incorporated by reference in their entirety). This prognostic index uses four components to predict probability of motor diagnosis, (1) total motor score (TMS) from the Unified Huntington's Disease Rating Scale (UHDRS), (2) Symbol Digit Modality Test (SDMT), (3) base-line age, and (4) cytosine-adenine-guanine (CAG) expansion.

**[00765]** In one embodiment, the prognostic index for Huntington's Disease is calculated with the following formula: $PI_{HD}$ = 51 x TMS+ (-34) x SDMT + 7 x Age x (CAG-34), wherein larger values for $PI_{HD}$ indicate greater risk of diagnosis or onset of symptoms.

**[00766]** In another embodiment, the prognostic index for Huntington's Disease is calculated with the following normalized formula that gives standard deviation units to be interpreted in the context of 50% 10-year survival: $PIN_{HD} = (PI_{HD} - 883)/1044$, wherein $PIN_{HD} < 0$ indicates greater than 50% 10-year survival, and $PIN_{HD} > 0$ suggests less than 50% 10-year survival.

**[00767]** In one embodiment, the prognostic index may be used to identify subjects whom will develop symptoms of HD within several years, but that do not yet have clinically diagnosable symptoms. Further, these asymptomatic patients may be selected for and receive treatment using the AAV vectors and compositions of the present invention during the asymptomatic period.

**[00768]** In one embodiment, the AAV particles may be administered to a subject who has undergone biomarker assessment. Potential biomarkers for brain imaging for premanifest and early progression of HD include, but are not limited to, striatal volume, subcortical white-matter volume, cortical thickness, whole brain and ventricular volumes, functional imaging (e.g., functional MRI), PET (e.g., with fluorodeoxyglucose), and magnetic resonance spectroscopy (e.g., lactate). Potential biomarkers for quantitative clinical tools for premanifest and early progression of HD include, but are not limited to, quantitative motor assessments, motor physiological assessments (e.g., transcranial magnetic stimulation), and quantitative eye movement measurements. Non-limiting examples of quantitative clinical biomarker assessments include tongue force variability, metronome-guided tapping, grip force, oculomotor assessments and cognitive tests. **[00771]** In one embodiment, the AAV particles may be administered to a subject who is in the early stages of HD. In the early stage a subject has subtle changes in coordination, some involuntary movements (chorea), changes in mood such as irritability and depression, problem solving difficulties, reduction in the ability of a person to function in their normal day to day life.

**[00772]** In one embodiment, the AAV particles may be administered to a subject who is in the middle stages of HD. In the middle stage a subject has an increase in the movement disorder, diminished speech, difficulty swallowing, and ordinary activities will become harder to do. At this stage a subject may have occupational and physical therapists to help maintain control of voluntary movements and a subject may have a speech language pathologist.

**[00773]** In one embodiment, the AAV particles may be administered to a subject who is in the late stages of HD. In the late stage, a subject with HD is almost completely or completely dependent on others for care as the subject can no longer walk and is unable to speak. A subject can generally still comprehend language and is aware of family and friends but choking is a major concern.

**[00774]** In one embodiment, the AAV particles may be used to treat a subject who has the juvenile form of HD which is the onset of HD before the age of 20 years and as early as 2 years.

**[00775]** In one embodiment, the AAV particles may be used to treat a subject with HD who has fully penetrant HD where the HTT gene has 41 or more CAG repeats (e.g., 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90 or more than 90 CAG repeats).

**[00776]** In one embodiment, the AAV particles may be used to treat a subject with HD who has incomplete penetrance where the HTT gene has between 36 and 40 CAG repeats (e.g., 36, 37, 38, 39 and 40 CAG repeats).

**[00777]** In some embodiments, the composition comprising the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention is administered to the central nervous system of the subject. In other embodiments, the composition comprising the AAV particles comprising modulatory polynucleotides encoding the siRNA

molecules of the present invention is administered to a tissue of a subject (e.g., brain of the subject).

**[00778]** In one embodiment, the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be delivered into specific types of targeted cells, including, but not limited to, neurons including medium spiny or cortical neurons; glial cells including oligodendrocytes, astrocytes and microglia; and/or other cells surrounding neurons such as T cells.

**[00780]** In some embodiments, the composition of the present invention for treating HD is administered to the subject in need intravenously, intramuscularly, subcutaneously, intraperitoneally, intraparenchymally, subpially, intrathecally and/or intraventricularly, allowing the siRNA molecules or vectors comprising the siRNA molecules to pass through one or both the blood-brain barrier and the blood spinal cord barrier, or directly access the brain and/or spinal cord. In some aspects, the method includes administering (e.g., intraparenchymal administration, subpial administration, intraventricular administration and/or intrathecal administration) directly to the central nervous system (CNS) of a subject (using, e.g., an infusion pump and/or a delivery scaffold) a therapeutically effective amount of a composition comprising AAV particles encoding the nucleic acid sequence for the siRNA molecules of the present invention. The vectors may be used to silence or suppress HTT gene expression, and/or reducing one or more symptoms of HD in the subject such that HD is therapeutically treated.

**[00781]** In some embodiments, the siRNA molecules or the AAV vectors comprising such siRNA molecules may be introduced directly into the central nervous system of the subject, for example, by infusion to the white matter a subject. While not wishing to be bound by theory, distribution via direct white matter infusion may be independent of axonal transport mechanisms which may be impaired in subjects with Huntington's Disease which means white matter infusion may allow for more transport of the AAV vectors.

**[00782]** In one embodiment, the composition comprising the AAV particles comprising modulatory polynucleotides encoding the siRNA molecules of the present invention is administered to the central nervous system of the subject via intraparenchymal injection.

**[00783]** In one embodiment, the AAV particle composition comprising modulatory polynucleotides encoding the siRNA molecules of the present invention is administered to the central nervous system of the subject via intraparenchymal injection and intrathecal injection.

**[00784]** In one embodiment, the AAV particle composition comprising modulatory polynucleotides encoding the siRNA molecules of the present invention is administered to the central nervous system of the subject via intraparenchymal injection and intracerebroventricular injection.

**[00785]** In some embodiments, the composition of the present invention for treating HD is administered to the subject in need by intraparenchymal administration.

**[00786]** In some embodiments, the AAV particle composition comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be introduced directly into the central nervous system of the subject, for example, by infusion into the putamen.

**[00787]** In some embodiments, the AAV particle composition comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be introduced directly into the central nervous system of the subject, for example, by infusion into the thalamus of a subject. While not wishing to be bound by theory, the thalamus is an area of the brain which is relatively spared in subjects with Huntington's Disease which means it may allow for more widespread cortical transduction via axonal transport of the AAV vectors.

**[00788]** In some embodiments, the AAV particle composition comprising modulatory polynucleotides encoding the siRNA molecules of the present invention may be introduced indirectly into the central nervous system of the subject, for example, by intravenous administration.

*Solo and Combination Therapy*

**[00810]** In some embodiments, the present composition is administered as a solo therapeutic or combination therapeutics for the treatment of HD.

**[00811]** In some embodiments, the pharmaceutical composition of the present invention is used as a solo therapy. In other embodiments, the pharmaceutical composition of the present invention is used in combination therapy. The combination therapy may be in combination with one or more neuroprotective agents such as small molecule compounds, growth factors and hormones which have been tested for their neuroprotective effect on neuron degeneration.

**[00812]** The AAV particles encoding siRNA duplexes targeting the HTT gene may be used in combination with one or more other therapeutic agents. By "in combination with," it is not intended to imply that the agents must be administered at the same time and/or formulated for delivery together, although these methods of delivery are within the scope of the present disclosure. Compositions can be administered concurrently with, prior to, or subsequent to, one or more other desired therapeutics or medical procedures. In general, each agent will be administered at a dose and/or on a time schedule determined for that agent.

**[00813]** Therapeutic agents that may be used in combination with the AAV particles encoding the nucleic acid sequence for the siRNA molecules of the present invention can be small molecule compounds which are antioxidants, anti-inflammatory agents, anti-apoptosis agents,

calcium regulators, antiglutamatergic agents, structural protein inhibitors, compounds involved in muscle function, and compounds involved in metal ion regulation.

**[00814]** Compounds tested for treating HD which may be used in combination with the vectors described herein include, but are not limited to, dopamine-depleting agents (e.g., tetrabenazine for chorea), benzodiazepines (e.g., clonazepam for myoclonus, chorea, dystonia, rigidity, and/or spasticity), anticonvulsants (e.g., sodium valproate and levetiracetam for myoclonus), amino acid precursors of dopamine (e.g., levodopa for rigidity which is particularly associate with juvenile HD or young adult-onset parkinsonian phenotype), skeletal muscle relaxants (e.g., baclofen, tizanidine for rigidity and/or spasticity), inhibitors for acetycholine release at the neuromuscular junction to cause muscle paralysis (e.g., botulinum toxin for bruxism and/or dystonia), atypical neuroleptics (e.g., olanzapine and quetiapine for psychosis and/or irritability, risperidone, sulpiride and haloperidol for psychosis, chorea and/or irritability, clozapine for treatment-resistant psychosis, aripiprazole for psychosis with prominent negative symptoms), agents to increase ATP/cellular energetics (e.g., creatine), selective serotonin reuptake inhibitors (SSRIs) (e.g., citalopram, fluoxetine, paroxetine, sertraline, mirtazapine, venlafaxine for depression, anxiety, obsessive compulsive behavior and/or irritability), hypnotics (e.g., xopiclone and/or zolpidem for altered sleep-wake cycle), anticonvulsants (e.g., sodium valproate and carbamazepine for mania or hypomania) and mood stabilizers (e.g., lithium for mania or hypomania).

**[00815]** Neurotrophic factors may be used in combination therapy with the AAV particles encoding the nucleic acid sequence for the siRNA molecules of the present invention for treating HD. Generally, a neurotrophic factor is defined as a substance that promotes survival, growth, differentiation, proliferation and /or maturation of a neuron, or stimulates increased activity of a neuron. In some embodiments, the present methods further comprise delivery of one or more trophic factors into the subject in need of treatment. Trophic factors may include, but are not limited to, IGF-I, GDNF, BDNF, CTNF, VEGF, Colivelin, Xaliproden, Thyrotrophin-releasing hormone and ADNF, and variants thereof.

**[00816]** In one aspect, the AAV particles comprising modulatory polynucleotides encoding the siRNA duplex targeting the HTT gene may be co-administered with AAV vectors expressing neurotrophic factors such as AAV-IGF-I (See e.g., Vincent et al., *Neuromolecular medicine*, 2004, 6, 79-85; the content of which is incorporated herein by reference in its entirety) and AAV-GDNF (See e.g., Wang et al., *J Neurosci*., 2002, 22, 6920-6928; the content of which is incorporated herein by reference in its entirety).

## V. DEFINITIONS

**[00817]** Unless stated otherwise, the following terms and phrases have the meanings described below. The definitions are not meant to be limiting in nature and serve to provide a clearer understanding of certain aspects of the present invention.

**[00818]** As used herein, the term "nucleic acid", "polynucleotide" and 'oligonucleotide" refer to any nucleic acid polymers composed of either polydeoxyribonucleotides (containing 2-deoxy-D-ribose), or polyribonucleotides (containing D-ribose), or any other type of polynucleotide which is an N glycoside of a purine or pyrimidine base, or modified purine or pyrimidine bases. There is no intended distinction in length between the term "nucleic acid", "polynucleotide" and "oligonucleotide", and these terms will be used interchangeably. These terms refer only to the primary structure of the molecule. Thus, these terms include double- and single-stranded DNA, as well as double- and single stranded RNA.

**[00819]** As used herein, the term "RNA" or "RNA molecule" or "ribonucleic acid molecule" refers to a polymer of ribonucleotides; the term "DNA" or "DNA molecule" or "deoxyribonucleic acid molecule" refers to a polymer of deoxyribonucleotides. DNA and RNA can be synthesized naturally, e.g., by DNA replication and transcription of DNA, respectively; or be chemically synthesized. DNA and RNA can be single-stranded (i.e., ssRNA or ssDNA, respectively) or multi-stranded (e.g., double stranded, i.e., dsRNA and dsDNA, respectively). The term "mRNA" or "messenger RNA", as used herein, refers to a single stranded RNA that encodes the amino acid sequence of one or more polypeptide chains.

**[00820]** As used herein, the term "RNA interfering" or "RNAi" refers to a sequence specific regulatory mechanism mediated by RNA molecules which results in the inhibition or interfering or "silencing" of the expression of a corresponding protein-coding gene. RNAi has been observed in many types of organisms, including plants, animals and fungi. RNAi occurs in cells naturally to remove foreign RNAs (e.g., viral RNAs). Natural RNAi proceeds via fragments cleaved from free dsRNA which direct the degradative mechanism to other similar RNA sequences. RNAi is controlled by the RNA-induced silencing complex (RISC) and is initiated by short/small dsRNA molecules in cell cytoplasm, where they interact with the catalytic RISC component argonaute. The dsRNA molecules can be introduced into cells exogenously. Exogenous dsRNA initiates RNAi by activating the ribonuclease protein Dicer, which binds and cleaves dsRNAs to produce double-stranded fragments of 21-25 base pairs with a few unpaired overhang bases on each end. These short double stranded fragments are called small interfering RNAs (siRNAs).

**[00821]** As used herein, the terms "short interfering RNA," "small interfering RNA" or "siRNA" refer to an RNA molecule (or RNA analog) comprising between about 5-60 nucleotides (or nucleotide analogs) which is capable of directing or mediating RNAi. Preferably, a siRNA molecule comprises between about 15-30 nucleotides or nucleotide analogs, such as between about 16-25 nucleotides (or nucleotide analogs), between about 18-23 nucleotides (or nucleotide analogs), between about 19-22 nucleotides (or nucleotide analogs) (e.g., 19, 20, 21 or 22 nucleotides or nucleotide analogs), between about 19-25 nucleotides (or nucleotide analogs), and between about 19-24 nucleotides (or nucleotide analogs). The term "short" siRNA refers to a siRNA comprising 5-23 nucleotides, preferably 21 nucleotides (or nucleotide analogs), for example, 19, 20, 21 or 22 nucleotides. The term "long" siRNA refers to a siRNA comprising 24-60 nucleotides, preferably about 24-25 nucleotides, for example, 23, 24, 25 or 26 nucleotides. Short siRNAs may, in some instances, include fewer than 19 nucleotides, e.g., 16, 17 or 18 nucleotides, or as few as 5 nucleotides, provided that the shorter siRNA retains the ability to mediate RNAi. Likewise, long siRNAs may, in some instances, include more than 26 nucleotides, e.g., 27, 28, 29, 30, 35, 40, 45, 50, 55, or even 60 nucleotides, provided that the longer siRNA retains the ability to mediate RNAi or translational repression absent further processing, e.g., enzymatic processing, to a short siRNA. siRNAs can be single stranded RNA molecules (ss-siRNAs) or double stranded RNA molecules (ds-siRNAs) comprising a sense strand and an antisense strand which hybridized to form a duplex structure called siRNA duplex.

**[00822]** As used herein, the term "the antisense strand" or "the first strand" or "the guide strand" of a siRNA molecule refers to a strand that is substantially complementary to a section of about 10-50 nucleotides, e.g., about 15-30, 16-25, 18-23 or 19-22 nucleotides of the mRNA of the gene targeted for silencing. The antisense strand or first strand has sequence sufficiently complementary to the desired target mRNA sequence to direct target-specific silencing, e.g., complementarity sufficient to trigger the destruction of the desired target mRNA by the RNAi machinery or process.

**[00823]** As used herein, the term "the sense strand" or "the second strand" or "the passenger strand" of a siRNA molecule refers to a strand that is complementary to the antisense strand or first strand. The antisense and sense strands of a siRNA molecule are hybridized to form a duplex structure. As used herein, a "siRNA duplex" includes a siRNA strand having sufficient complementarity to a section of about 10-50 nucleotides of the mRNA of the gene targeted for silencing and a siRNA strand having sufficient complementarity to form a duplex with the other siRNA strand.

**[00824]** As used herein, the term "complementary" refers to the ability of polynucleotides to form base pairs with one another. Base pairs are typically formed by hydrogen bonds between nucleotide units in antiparallel polynucleotide strands. Complementary polynucleotide strands can form base pair in the Watson-Crick manner (e.g., A to T, A to U, C to G), or in any other manner that allows for the formation of duplexes. As persons skilled in the art are aware, when using RNA as opposed to DNA, uracil rather than thymine is the base that is considered to be complementary to adenosine. However, when a U is denoted in the context of the present invention, the ability to substitute a T is implied, unless otherwise stated. Perfect complementarity or 100% complementarity refers to the situation in which each nucleotide unit of one polynucleotide strand can form hydrogen bond with a nucleotide unit of a second polynucleotide strand. Less than perfect complementarity refers to the situation in which some, but not all, nucleotide units of two strands can form hydrogen bond with each other. For example, for two 20-mers, if only two base pairs on each strand can form hydrogen bond with each other, the polynucleotide strands exhibit 10% complementarity. In the same example, if 18 base pairs on each strand can form hydrogen bonds with each other, the polynucleotide strands exhibit 90% complementarity.

**[00825]** As used herein, the term "substantially complementary" means that the siRNA has a sequence (e.g., in the antisense strand) which is sufficient to bind the desired target mRNA, and to trigger the RNA silencing of the target mRNA.

**[00826]** As used herein, "targeting" means the process of design and selection of nucleic acid sequence that will hybridize to a target nucleic acid and induce a desired effect.

**[00827]** The term "gene expression" refers to the process by which a nucleic acid sequence undergoes successful transcription and in most instances translation to produce a protein or peptide. For clarity, when reference is made to measurement of "gene expression", this should be understood to mean that measurements may be of the nucleic acid product of transcription, e.g., RNA or mRNA or of the amino acid product of translation, e.g., polypeptides or peptides. Methods of measuring the amount or levels of RNA, mRNA, polypeptides and peptides are well known in the art.

**[00828]** As used herein, the term "mutation" refers to any changing of the structure of a gene, resulting in a variant (also called "mutant") form that may be transmitted to subsequent generations. Mutations in a gene may be caused by the alternation of single base in DNA, or the deletion, insertion, or rearrangement of larger sections of genes or chromosomes.

**[00829]** As used herein, the term "vector" means any molecule or moiety which transports, transduces or otherwise acts as a carrier of a heterologous molecule such as the siRNA molecule of the invention. A "viral genome" or "vector genome" or "viral vector" refers to a sequence which comprises one or more polynucleotide regions encoding or comprising a molecule of interest, e.g., a transgene, a polynucleotide encoding a polypeptide or multi-polypeptide or a modulatory nucleic acid such as small interfering RNA (siRNA). Viral genomes are commonly used to deliver genetic materials into cells. Viral genomes are often modified for specific applications. Types of viral genome sequence include retroviral viral genome sequences, lentiviral viral genome sequences, adenoviral viral genome sequences and adeno-associated viral genome sequences.

**[00830]** The term "adeno-associated virus" or "AAV" as used herein refers to any vector which comprises or derives from components of an adeno-associated vector and is suitable to infect mammalian cells, preferably human cells. The term AAV vector typically designates an AAV type viral particle or virion comprising a payload. The AAV vector may be derived from various serotypes, including combinations of serotypes (i.e., "pseudotyped" AAV) or from various genomes (e.g., single stranded or self-complementary). In addition, the AAV vector may be replication defective and/or targeted.

**[00831]** As used herein, the phrase "inhibit expression of a gene" means to cause a reduction in the amount of an expression product of the gene. The expression product can be a RNA molecule transcribed from the gene (*e.g.*, an mRNA) or a polypeptide translated from an mRNA transcribed from the gene. Typically a reduction in the level of an mRNA results in a reduction in the level of a polypeptide translated therefrom. The level of expression may be determined using standard techniques for measuring mRNA or protein.

**[00832]** As used herein, the term "*in vitro*" refers to events that occur in an artificial environment, *e.g.*, in a test tube or reaction vessel, in cell culture, in a Petri dish, *etc.*, rather than within an organism (*e.g.*, animal, plant, or microbe).

**[00833]** As used herein, the term "*in vivo*" refers to events that occur within an organism (*e.g.*, animal, plant, or microbe or cell or tissue thereof).

**[00834]** As used herein, the term "modified" refers to a changed state or structure of a molecule of the invention. Molecules may be modified in many ways including chemically, structurally, and functionally.

**[00835]** As used herein, the term "synthetic" means produced, prepared, and/or manufactured by the hand of man. Synthesis of polynucleotides or polypeptides or other molecules of the present invention may be chemical or enzymatic.

**[00836]** As used herein, the term "transfection" refers to methods to introduce exogenous nucleic acids into a cell. Methods of transfection include, but are not limited to, chemical methods, physical treatments and cationic lipids or mixtures. The list of agents that can be transfected into a cell is large and includes, but is not limited to, siRNA, sense and/or anti-sense sequences, DNA encoding one or more genes and organized into an expression plasmid, proteins, protein fragments, and more.

**[00837]** As used herein, "off target" refers to any unintended effect on any one or more target, gene, or cellular transcript.

**[00838]** As used herein, the phrase "pharmaceutically acceptable" is employed herein to refer to those compounds, materials, compositions, and/or dosage forms which are, within the scope of sound medical judgment, suitable for use in contact with the tissues of human beings and animals without excessive toxicity, irritation, allergic response, or other problem or complication, commensurate with a reasonable benefit/risk ratio.

**[00839]** As used herein, the term "effective amount" of an agent is that amount sufficient to effect beneficial or desired results, for example, clinical results, and, as such, an "effective amount" depends upon the context in which it is being applied. For example, in the context of administering an agent that treats HD, an effective amount of an agent is, for example, an amount sufficient to achieve treatment, as defined herein, of HD, as compared to the response obtained without administration of the agent.

**[00840]** As used herein, the term "therapeutically effective amount" means an amount of an agent to be delivered (*e.g.*, nucleic acid, drug, therapeutic agent, diagnostic agent, prophylactic agent, *etc.*) that is sufficient, when administered to a subject suffering from or susceptible to an infection, disease, disorder, and/or condition, to treat, improve symptoms of, diagnose, prevent, and/or delay the onset of the infection, disease, disorder, and/or condition.

**[00841]** As used herein, the term "subject" or "patient" refers to any organism to which a composition in accordance with the invention may be administered, *e.g.*, for experimental, diagnostic, prophylactic, and/or therapeutic purposes. Typical subjects include animals (*e.g.*, mammals such as mice, rats, rabbits, non-human primates such as chimpanzees and other apes and monkey species, and humans) and/or plants.

**[00842]** As used herein, the term "preventing" or "prevention" refers to delaying or forestalling the onset, development or progression of a condition or disease for a period of time, including weeks, months, or years.

**[00843]** The term "treatment" or "treating," as used herein, refers to the application of one or more specific procedures used for the cure or amelioration of a disease. In certain embodiments, the specific procedure is the administration of one or more pharmaceutical agents. In the context of the present invention, the specific procedure is the administration of one or more siRNA molecules.

**[00844]** As used herein, the term "amelioration" or "ameliorating" refers to a lessening of severity of at least one indicator of a condition or disease. For example, in the context of neurodegeneration disorder, amelioration includes the reduction of neuron loss.

**[00845]** As used herein, the term "administering" refers to providing a pharmaceutical agent or composition to a subject.

**[00846]** As used herein, the term "neurodegeneration" refers to a pathologic state which results in neural cell death. A large number of neurological disorders share neurodegeneration as a common pathological state. For example, Alzheimer's disease, Parkinson's disease, Huntington's disease, and amyotrophic lateral sclerosis (ALS) all cause chronic neurodegeneration, which is characterized by a slow, progressive neural cell death over a period of several years, whereas acute neurodegeneration is characterized by a sudden onset of neural cell death as a result of ischemia, such as stroke, or trauma, such as traumatic brain injury, or as a result of axonal transection by demyelination or trauma caused, for example, by spinal cord injury or multiple sclerosis. In some neurological disorders, mainly one type of neuronal cell is degenerative, for example, medium spiny neuron degeneration in early HD.

## VII. EXAMPLES

### Example 1. *In Vivo* YAC128 Mouse Study of HTT Suppression, Guide to Passenger Ratio and Precision of 5' End Processing after Treatment with AAV1-miRNA Vectors Produced in Mammalian Cells

**[00854]** Based on *in vitro* suppression of HTT with plasmid transfection and with infection of AAV packaged AAV-miRNA expression vectors, selected AAV-miRNA expression vectors were packaged in AAV1 and evaluated in vivo in YAC128 mice, to quantify HTT mRNA suppression, and to assess guide to passenger strand ratio and the precision of 5' end processing by deep sequencing. The AAV-miRNA transgene genomes were packaged in AAV1 with a CBA promoter (AAV1.CBA.iHtt), and then, the vectors were produced by triple transfection in HEK293 or HEK293T cells, purified and formulated in phosphate buffered saline (PBS) with 0.001% F-68. The vectors were administered to YAC128 mice 7-12 weeks of age via bilateral intrastriatal infusion at a dose of approximately 1E10 to 3E10 vg in 5 uL over 10 minutes per hemisphere. A control group was treated with vehicle (PBS with 0.001% F-68). Each group comprised 4 females and 4 males. Approximately 28 days following test article administration, striatum tissue punches were collected and snap-frozen for later analysis.

**[00855]** Striatum tissue samples were then homogenized and total RNAs were purified. The relative expression of HTT was determined by qRT-PCR. Housekeeping genes for normalization included mouse XPNPEP1 (X-Prolyl Aminopeptidase 1) and mouse HPRT (hypoxanthine-guanine phosphoribosyltransferase). HTT mRNA was normalized to housekeeping gene expression, and then further normalized to the vehicle group. The total dose (vg/ mouse), and constructs are shown in Table 41. The results are shown in Tables 42 and 43.

**[00858]** VOYHT43, VOYHT15, VOYHT46, VOYHT48, VOYHT40, and VOYHT47 were shown to have good Htt mRNA knockdown as compared to the other constructs. VOYHT37, VOYHT46, VOYHT44, and VOYHT39 were considered to have a low guide to passenger strand ratio (G:P ratio) as they had a ratio of less than 4. VOYHT43 and VOYHT45 had abundance relative to total miRNA reads which was greater than 10% and considered too high for additional studies. VOYHT48, VOYHT40 and VOYHT47 were selected for additional studies.

**Example 2. AAV-miRNA Expression Vectors**

**[00859]** The constructs comprising the pri-miRNA cassettes containing guide strands targeting HTT and passenger strands were engineered into AAV-miRNA expression vectors (either ss or sc). The AAV-miRNA expression vector construct from ITR to ITR, recited 5' to 3', comprises a mutant or wild type ITR, a promoter (either a CMV (which includes an SV40 intron or a human betaglobin intron), U6, H1, CBA (which includes a CMVie enhancer, a CB promoter and an SV40 intron or a human betaglobin intron), or CAG promoter (which includes a CMVie enhancer, a CB promoter, and a rabbit betaglobin intron or a human betaglobin intron), the pri-miRNA cassette containing guide strand sequence targeting HTT and passenger strand sequence, a rabbit globin polyA or human growth hormone polyA and wild type ITR. In vitro and in vivo studies are performed to evaluate the pharmacological activity of the AAV-miRNA expression vectors.

**Example 3. *In Vivo* YAC128 Mouse Study of HTT Suppression, Guide to Passenger Strand Ratio and Precision of Processing after Treatment with AAV-miRNA Vectors Produced with the Baculo / Sf9 System**

**[00860]** Three constructs comprising the pri-miRNA cassettes containing guide strands targeting HTT and passenger strands were engineered into scAAV-miRNA expression vectors designed for baculo/Sf9 production. The scAAV-miRNA expression construct from ITR to ITR, recited 5' to 3', comprised a wild type ITR, a CBA promoter (which includes a CMVie enhancer, a CB promoter and an SV40 intron), the pri-miRNA cassette containing guide strand sequence targeting HTT and passenger strand sequence, a rabbit globin polyA, a stuffer sequence, and

wild type ITR. The vectors were produced in the baculo/Sf9 system, purified and formulated in phosphate buffered saline (PBS) with 0.001% F-68, and then administered to YAC128 mice 7-12 weeks of age via bilateral intrastriatal infusion of 5 µL vector at 0.5 µL/min, with a vector concentration of $3.6 \times 10^{12}$ vg/mL; the total dose was $3.6 \times 10^{10}$ vg. A control group was treated with vehicle (PBS with 0.001% F-68). Each group comprised 4 females and 4 males. Approximately 28 days following test article administration, striatum tissue punches were collected and snap-frozen. Striatum tissue samples were homogenized and total RNAs were purified, and the relative expression of HTT mRNA was determined by qRT-PCR. The housekeeping gene for normalization was mouse XPNPEP1 (X-Prolyl Aminopeptidase 1). HTT mRNA was normalized to housekeeping gene expression, and then further normalized to the vehicle group. The HTT mRNA results are shown in Table 45.

***Example 4. In Vivo Study in Non-Human Primates***

*Study Design*

**[00862]** A study in rhesus monkeys was conducted to evaluate HTT suppression, precision, and efficiency of pri-miRNA processing, tolerability, and distribution of vector genomes within the CNS. Selected constructs comprising the pri-miRNA cassettes containing guide strands targeting HTT and passenger strands were engineered into scAAV-miRNA expression vectors designed for baculo/Sf9 production. The scAAV-miRNA expression construct from ITR to ITR, recited 5' to 3', comprised a wild type ITR, a CBA promoter (which includes a CMVie enhancer, a CB promoter and an SV40 intron), the pri-miRNA cassette containing guide strand sequence targeting HTT and passenger strand sequence, a rabbit globin polyA, a stuffer sequence, and wild type ITR. The vectors were produced in the baculo/Sf9 system, purified and formulated in phosphate buffered saline (PBS) with 0.001% F-68.

**[00863]** Four groups of rhesus monkeys received vehicle (n=3) or one of three vectors (n=6 per group) as bilateral intraputamenal infusions of 100 µL/side at 3 – 5 µL/min. Gadoteridol (2 mM; ProHance) was co-infused. For animals receiving a vector, the same vector was infused on both sides, with the right side receiving a concentration of $9 \times 10^{11}$ vg/mL and the left side receiving a concentration of $2.7 \times 10^{12}$ vg/mL. The total dose of vector administered was $9 \times 10^{10}$ vg (low dose) or $2.7 \times 10^{11}$ vg (high dose) per putamen, or $3.6 \times 10^{11}$ vg per animal. All animals were euthanized after five weeks. The study design is shown in Table 46.

*HTT mRNA Analysis*

**[00864]** HTT mRNA suppression was evaluated in 2 mm tissue punches from the putamen, using branched DNA (bDNA) for quantifying HTT mRNA levels. For each group receiving vector, a total of 60 punches were evaluated per dose of vector (10 punches per putamen, 6 animals per dose of vector). From the vehicle group, 10 punches per putamen were taken from each of 3 animals. HTT mRNA was normalized to the geometric mean of housekeeping genes TATA-box binding protein (TBP), alanyl-tRNA synthetase (AARS) and X-prolyl aminopeptidase 1 (XPNPEP1), and then further normalized to the vehicle group. The HTT mRNA results are shown in Tables 47 and 48.

*Vector Genome Quantitation*

**[00865]** From the same 2 mm tissue punches from the putamen (with high and low dose treatments) that were used for quantifying HTT mRNA levels by bDNA, a portion of the tissue lysate was used for vector genome copy (VG) determination by droplet digital PCR. For Group 1 (VOYHT1) and Group 3 (VOYHT4), approximately 50% HTT mRNA suppression was achieved with approximately 10 VG copies per diploid cell. For Group 2 (VOYHT3), approximately 50% HTT mRNA suppression was achieved with approximately 400 VG copies per diploid cell. The results are shown in Table 49 (high dose, 2.7E12 vg/mL) and Table 50 (low dose, 0.9E12 vg/mL).

*Pri-miRNA Processing*

**[00866]** Precision and efficiency of pri-miRNA processing were evaluated by deep sequencing of 2 mm punches from the putamen, from the high and low dose treatments, to assess guide:passenger strand ratio, abundance of guide and passenger strands relative to the total endogenous pool of miRNAs, and precision of processing at the 5'-end of the guide strand. These results are shown in Table 51.

*Tolerability Results*

**[00867]** Body weight assessments were acquired on Day -8 (i.e., 8 days prior to dosing of the first animal), Day 1, and each week thereafter until termination on Day 36±3. There was no significant change in the average body weights in each group throughout the 5 week in-life period.

**[00868]** Cage-side observations were performed twice daily (a.m. and p.m.) beginning on Day -8 until scheduled necropsy, to assess abnormalities including neurological signs, and signs of pain or distress, as well as changes in general health, appearance, and behavior. In addition,

beginning on Day -8, food consumption was assessed qualitatively once per day. Only decreased appetence was noted in a few animals following surgery; this is considered a common finding post-surgery. Food consumption returned to normal within the first week and remained normal for the remainder of the study.

**[00869]** Blood was collected on Day -8, Day 15±2, and Day 36±3 for evaluation of hematology, serum chemistry, and coagulation. Hematology assessments comprised WBC, RBC, HGB, HCT, MCV, MCH, MCHC, PLT (qualitative assessment), and absolute and relative values for NEUT, LYMPH, MONO, EOS, and BASO. Serum chemistry comprised TP, ALB, GLOB, A/G ratio, ALP ALT, AST, TBIL (direct and indirect), BUN, CREAT, Ca CHOL, GLU, Phos, TCO2, Na, K and Cl. Coagulation comprised PT, A-PTT and fibrinogen. Although some values fell outside of the normal limits, they were interpreted as physiological variations in the absence of any clinical correlation during in-life.

**[00870]** At necropsy, no abnormalities in gross pathology were observed.

**[00871]** Histopathology was conducted on the putamen including the infusion site. For all animals, a 3 mm thick coronal brain slab containing the putamen was fixed by immersion in 4% paraformaldehyde for 72 to 96 hours at room temperature and then transferred to phosphate buffered saline (PBS) for storage at approximately +4degC. The 3 mm brain slabs were then embedded in paraffin and coronally sectioned. Full coronal sections, 5 um thick, containing the infusion site in the putamen were assessed for pathology by standard hematoxylin and eosin staining. The vehicle control group was consistent with what would be expected to occur with any injection into the putamen, i.e. the reactions were typical for those associated with a needle track. In Groups 1, 2, and 3, each animal treated with one of three vectors exhibited pathology findings comprised of mild focal gliosis from the needle track, minimal to mild perivascular infiltrates and/or occasional edema most likely due to a combination of trauma from the injection and reaction to the AAV. There were no pathology findings that were considered adverse, given the absence of clinical symptoms.

**[00873]** The miRNA expression vectors which were approximately 2300 nucleotides in length had a higher genome quality as compared to the vectors having approximately 1500 nucleotides or 1900 nucleotides. **Example 6. Quality Control of Vectors Produced with the Baculo / Sf9 System in Large Scale**

**[00874]** The miRNA expression vectors of the present disclosure were produced by using a Baculo/Sf9 system on a 1L scale. A cesium chloride (CsCl) gradient analysis was used in addition to standard purification techniques to ensure a high % of full vectors. The achieved % of full vectors was at least 80%. Titers ranged from 0.9E12 to 4E13 vg/L of culture, and the vectors with a 5' or 3' filler sequence vectors presented the highest titers. The quality of the genome packaged in the vectors of the present disclosure was evaluated by using alkaline denaturing gel analysis, showing a high level of genome quality. The gel banding patterns for the 1L scale production was similar to the small scale production pattern. The purity of the vectors of the present invention was evaluated by using silver stain PAGE analysis, showing good VP1, VP2, and VP3 ratio and purity.

For HEK293T, the cells were plated into 96-well plates (2.5E4 cells/well in 100 ul cell culture medium) and infected with the miRNA expression vectors. 60 hours after infection, the cells were harvested for immediate cell lysis, RNA isolation and qRT-PCR and the levels of HTT were calculated compared to a GFP transduction control.
