Title: 5,6,7,8-TETRAHYDRO-IMIDazo[I 5,7]-A]PYRAZINE DERIVATIVES

Abstract: The invention relates to 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives of formula (I), wherein X represents CH= or O; R represents a phenyl group, which group is independently mono-, di-, or tri-substituted wherein the substituents are independently selected from the group consisting of (C1-C6)alkyl, (C1-C6)alkoxy, halogen, cyano, trifluoromethoxy and trifluoromethyl; R' represents (C1-C6)alkyl, (C1-C6)alkoxy, (C2-C6)alkenyl, halogen, cyano, hydroxymethyl, trifluoromethyl, C(O)NR= alkyl or cyclopropyl; R" represents (C1-C6)alkyl, (C1-C6)alkoxy-methyl or halogen; R" represents (C1-C6)alkyl; R" represents hydrogen or (C1-C6)alkyl; and R" represents hydrogen or (C1-C6)alkyl. The invention also relates to pharmaceutically acceptable salts of such compounds; and to the use of such compounds as medicaments; especially as orexin receptor antagonists.
The present invention relates to novel 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives of formula (I) and their use as pharmaceuticals. The invention also concerns related aspects including processes for the preparation of the compounds, pharmaceutical compositions containing one or more compounds of formula (I), and especially their use as orexin receptor antagonists.

Orexins (orexin A or OX-A and orexin B or OX-B) are novel neuropeptides found in 1998 by two research groups, orexin A is a 33 amino acid peptide and orexin B is a 28 amino acid peptide (Sakurai T. et al., Cell, 1998, 92, 573-585). Orexins are produced in discrete neurons of the lateral hypothalamus and bind to the G-protein-coupled receptors (OX1 and OX2 receptors). The orexin-1 receptor (OX1) is selective for OX-A, and the orexin-2 receptor (OX2) is capable to bind OX-A as well as OX-B. Orexins are found to stimulate food consumption in rats suggesting a physiological role for these peptides as mediators in the central feedback mechanism that regulates feeding behaviour (Sakurai T. et al., Cell, 1998, 92, 573-585). On the other hand, it was also observed that orexins regulate states of sleep and wakefulness opening potentially novel therapeutic approaches to narcolepsy as well as insomnia and other sleep disorders (Chemelli R.M. et al., Cell, 1999, 98, 437-451).

Orexin receptors are found in the mammalian brain and may have numerous implications in pathologies as known from the literature.

Up to now, some low molecular weight compounds are known having a potential to antagonise either specifically OX1 or OX2, or both receptors at the same time. In WO01/85693, Banyu Pharmaceuticals claimed Λ-acyltetrahydroisoquinoline derivatives. Other orexin receptor antagonists such as novel benzazepine derivatives are disclosed in WO02/051838. Pyrazolo-tetrahydropyridine derivatives as orexin receptor antagonists are known from WO07/122591.

Furthermore, the use of solution-phase chemistry for the lead optimization of 1,2,3,4-tetrahydroisoquinoline derivatives as potential orexin receptor antagonists has been reported (Chimia, 2003, 57, 270-275).
The present invention provides novel substituted 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives, which are non-peptide antagonists of human orexin OX₁ and/or OX₂ receptors. These compounds are in particular of potential use in the treatment of e.g. eating disorders, drinking disorders, sleep disorders, or cognitive dysfunctions in psychiatric and neurologic disorders.

Various embodiments of the invention are presented hereafter:

Compounds of general formula (I) and (II) belonging to this invention could be prepared according to several synthetic routes described below (schemes 1 to 13). All chemical transformations can be performed according to well-known standard methodologies as described in the literature or as described in the procedures below. Starting materials are commercially available or prepared according to procedures known in the literature or as illustrated herein. Some of the examples may be further modified by manipulation of substituents to result in additional examples. These manipulations may include, but are not limited to, reduction, oxidation, alkylation, acylation, and hydrolysis reactions which are commonly known to those skilled in the art. The order of carrying out the foregoing reaction schemes may be varied to facilitate the reaction or to avoid side-products.

An overview of the general synthetic route is presented in scheme 1. Tri-substituted-imidazole derivatives represented key intermediates in this synthesis and therefore their regioselective preparation was envisaged. Thus, the issue of tautomerism associated with imidazoles (and leading to isomeric mixtures) was circumvented in this approach through
the use of pseudosymmetric 4,5-diiodoimidazole derivatives. Diiodination (\(1/2\)Na\(_2\)CO\(_3\)) of 2-substituted imidazoles A (from commercial sources or from regioselective syntheses as described in \textit{scheme 5}) gave the corresponding 4,5-diiodoimidazoles B. Deprotonation of pseudosymmetric B (NaH/DMF) and subsequent \(\mathcal{N}\)-alkylation with (2-bromo-ethyl)-carbamic acid tert-butyl ester furnished exclusively the product C. The pivotal step of this synthetic route was the efficient preparation of the corresponding 4-iodoimidazoles D by using a regioselective exchange of the 5-iodo moiety for MgBr (EtMgBr/THF/-40°C) followed by trapping of the carbanion with water. This process proved to be highly regioselective and only the expected 4-iodoimidazole derivatives D could be detected (as evidenced by \(^1\)H-NMR). Moreover this approach afforded an operational, convenient and rapid synthesis of these key substrates and could be accomplished on a multigram-scale (see experimental part). Boc-deprotection of D led smoothly to the corresponding primary amines E which were allowed to react with aldehydes R\(^1\)-X-CH\(_2\)-CHO in a microwave-assisted \textit{Pictet-Spengler} like reaction. Subsequent Boc-protection and purification gave the expected 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives F with good to high overall yields. The versatility of the iodo-substituent allowed the access to a variety of derivatives G (see \textit{scheme 6} for the introduction of diverse functional groups and substituents). Boc-deprotection of G followed by \(\mathcal{N}\)-alkylation with electrophiles H (see \textit{schemes 4 and 13}) furnished the compounds of formula (I) and (II).

The additional building block O was synthesized ('\textit{scheme 2}') in order to prepare some specific compounds of formula (I) and (II) containing either R\(^3\) substituents which would be too sensitive and therefore incompatible with the quite harsh reaction conditions of the microwave-assisted \textit{Pictet-Spengler} like reaction or containing specific R\(^2\)/R\(^3\) combinations which would not be conveniently incorporated by application of the general synthesis depicted in \textit{scheme 1}. Iodination of imidazole J (\(1/2\)Na\(_2\)CO\(_3\)) led smoothly to 2,4,5-triiodo-1/-imidazole K which was \(\mathcal{N}\)-alkylated (NaHZBrCH\(_2\)CH\(_2\)NHBoC) giving compound L. Regioselective one-pot removal of two iodo-substituents with ethylimagnesium bromide (first on position-2, and secondly on position-5) furnished exclusively the expected 4-iodoimidazole derivative M which was Boc-deprotected (HCl in dioxane). The obtained primary amine N was then allowed to react with aldehydes R\(^1\)-X-CH\(_2\)-CHO in a microwave-assisted \textit{Pictet-Spengler} like reaction. Subsequent Boc-protection and purification afforded
the 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives O. With this building block O in hand, the planned specific combinations of R²/R³ substituents could be introduced by iodine/metal exchange and trapping of the resulting carbanion with appropriate electrophiles, by transition metal-catalyzed cross-coupling reactions (mainly StMe cross-coupling reactions), and by aromatic electrophilic substitution reactions performed on the imidazole moiety (scheme 2). This synthetic route was particularly appropriate for the preparation of compounds of formula (I) and (II) with R³ representing halogen.
wherein $X$, $R_1$, $R_2$, $R_3$, $R_4$ are as described above, and $Z$ is Br or OTs.

**Scheme 1**: General synthetic route allowing the preparation of compounds of formula (I) and (II).
wherein X, R\textsubscript{1}, R\textsubscript{2}, R\textsubscript{3} and R\textsubscript{4} are as described above.

Scheme 2: Preparation of building block O allowing introduction of specific R\textsubscript{2}/R\textsubscript{3} substituents.

As shown in scheme 3, specific R\textsubscript{2}-substituents could be also advantageously introduced at the earlier stage of imidazole derivative D in order to avoid side-reactions susceptible to occur in the remaining steps (e.g. aromatic nucleophilic substitution reactions with some specifically substituted R\textsubscript{1} residues). Remaining steps affording compounds of general formula (I) and (II) were as previously described in scheme 1.
wherein $X$, $R^1$, $R^2$, $R^3$ and $R^4$ are as described above.

Scheme 3: Earlier introduction of some specific $R^2$-substituents.

In a slightly different synthetic route, secondary amine $Q$ could be $N$-alkylated with ester derivative $R$ (instead of amide derivative $H$) affording intermediate $S$ which can either be directly transformed into target compounds $\dagger$ (by reaction with amine $R^4\text{-NH}_2$) or which can be first hydrolyzed to the corresponding carboxylic acid $T$ followed by coupling with amine $R^4\text{-NH}_2$ (*scheme 4*).
wherein $X$, $R_1$, $R_2$, $R_3$ and $R_4$ are as described above.

Scheme 4: $\Lambda /$-alkylation of 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazines.

A variety of useful 2-substituted imidazoles $\mathcal{A}$ were conveniently obtained either from commercial sources or from regioselective synthesis (scheme 5). Treatment of 1-trityl-1-$H$-imidazole with n-butyllithium allowed the abstraction of the most acidic H-2 hydrogen and the generation of the corresponding carbanion. In a next step, this carbanion can react with electrophiles to form 1-trityl-2-E-imidazoles. The triphenylmethyl group could be smoothly removed by acid hydrolysis ($\text{AcOH}/\text{MeOH}$) to give the expected 2-substituted imidazoles $\mathcal{A}$. Selected preparations are exemplified in scheme 5 but are not limited to these examples. All the introduced functional groups and substituents could be used for further derivatization (elaboration of $R^3$ substituents). Thus, iodine constituted a useful electrophile for the efficient synthesis of 2-iodimidazole derivatives. Moreover 2-iodo-1-trityl-1-$H$-imidazole represented a versatile starting material for the preparation of additional 2-substituted imidazoles via palladium-catalyzed cross-coupling reactions (mainly StMe cross-coupling reactions). 1-Trityl-1$H$-imidazole-2-carbaldehyde could be also obtained.
regioselectively and efficiently (after trapping with DMF) allowing further functional group interconversions and therefore access to 2-alkoxymethyl-1/-/-imidazole (after reduction of the aldehyde moiety and subsequent O-alkylation).

**Scheme 5:** Regioselective preparation of 2-substituted imidazoles.

The versatility of the iodo-substituent in 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazines \(F\) allowed the access to a variety of derivatives, as exemplified in *scheme 6*. Thus, treatment of \(F\) with n-butyllithium followed by trapping of the resulting carbanion with hexachloroethane afforded the chloro-derivative. Alkoxy-residues could be introduced by copper(I)-catalyzed and microwave-assisted alkoxylation of \(F\) (ROH/Cul/1,10-phenanthroline/Cs\(_2\)CO\(_3\)). The carbanion generated after iodine/metal exchange could be smoothly trapped with \(N,N\)-dimethylformamide and the introduced formyl-moiety could be additionally manipulated for the preparation of several derivatives (*scheme 6a and 6b*). Moreover, trapping of the previous carbanion with CO\(_2\) allowed the direct preparation of
carboxylic acid derivatives which in turn could be converted to amides. The iodo-substituent also allowed the introduction of a trifluoromethyl group via copper(I)-catalyzed trifluoromethylation (FSO₂CF₂CO₂Me / CuI). StMe cross-coupling reactions performed with iodo-imidazoles are well documented in the literature, and in our case 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazines reacted smoothly in such reactions with a variety of organotin derivatives (e.g. with n-tributyl(vinyl)tin).

wherein X, R¹, R³, R⁵ and R⁶ are as described above, R⁷ represents (C₁₋₄)alkyl and R⁸ represents (Cₛ₋₂)alkyl.

wherein X, R1, R3, R5 and R6 are as described above, R" represents (C1₄)alkyl and R"" represents (C1₅)alkyl.

Scheme 6b: Use of the versatility of the iodo-substituent for the preparation of derivatives.

The preparation of some compounds of formula (I) and (II) could be directly undertaken starting with appropriately disubstituted imidazoles (commercially available or synthesized; scheme 7). Thus, N-alkylation of 2,4-substituted imidazoles with 2-chloroethylamine hydrochloride (in the presence of powdered NaOH and catalytic amounts of tetrabutylammonium hydrogensulfate) afforded a mixture of isomeric products including the expected compound I. Subsequent microwave-assisted Pictet-Spengler like reaction with aldehydes R1-X-CH₂-CHO furnished the expected 5,6,7,8-tetrahydro-imidazo[1,5-a]pyrazine derivatives Q which could be transformed to compounds of formula (I) and (II) according to previously described procedures.
wherein X, R<sub>1</sub>, R<sub>2</sub>, R<sub>3</sub> and R<sub>4</sub> are as described above.

**Scheme 7**: Preparation of compounds of formula (I) and (II) starting with 2,4-substituted imidazoles.

Aldehydes R<sup>1</sup>-X-CH<sub>2</sub>-CHO were pivotal reagents for the preparation of compounds of formula (I) and (II) and several synthetic methods allowed their efficient preparation.

Thus, aldehydes R<sup>1</sup>-CH<sub>2</sub>-CH<sub>2</sub>-Cl-IO (X = CH<sub>2</sub>) were readily prepared by reduction of the corresponding hydrocinnamic acids (BH<sub>3</sub>·THF) and subsequent oxidation of the obtained alcohols with PCC (scheme 8). Preliminary hydrogenation of commercially available cinnamic acids allowed a convenient access to unavailable hydrocinnamic acid precursors (scheme 8).

![Scheme 7: Preparation of compounds of formula (I) and (II) starting with 2,4-substituted imidazoles.](image)

Scheme 7: Preparation of compounds of formula (I) and (II) starting with 2,4-substituted imidazoles.

Closely related to this method of preparation, another short and convenient synthesis of diversely substituted propanol derivatives was the reduction of corresponding propionic acid methyl esters (scheme 9).

![Scheme 8: Synthesis of aldehydes R<sup>1</sup>-CH<sub>2</sub>-CH<sub>2</sub>-CHO from cinnamic or hydrocinnamic acids.](image)

Scheme 8: Synthesis of aldehydes R<sup>1</sup>-CH<sub>2</sub>-CH<sub>2</sub>-CHO from cinnamic or hydrocinnamic acids.
wherein $R^1$ is as described above.

Scheme 9: Synthesis of aldehydes $R^1$-CH$_2$-CH$_2$-Cl-IO from propionic acid methyl esters.

In case neither cinnamic acids nor hydrocinnamic acids were commercially available, additional synthetic routes allowed their successful preparation. Thus, a convenient synthesis was based on a Knoevenagel condensation as depicted in scheme 10. Knoevenagel condensation between aryl aldehydes $R^1$CHO and malonic acid (in pyridine and in the presence of piperidine) gave the expected cinnamic acid derivatives. Catalytic hydrogenation under standard conditions (1 atm $H_2$; 10% Pd(C); MeOH; rt) afforded the corresponding hydrocinnamic acids which were converted to the corresponding aldehydes $R^1$-CH$_2$-CH$_2$-CHO by the previously described reduction/oxidation sequence (scheme 10).

Scheme 10: Preparation of hydrocinnamic acids and aldehydes $R^1$-CH$_2$-CH$_2$-CHO via Knoevenagel condensation.

An alternative preparation of hydrocinnamic acids was based on a Heck reaction between aryl halides and n-butyl acrylate (with Pd(OAc)$_2$/DABCO as catalytic system; scheme 11). Palladium-catalyzed hydrogenation and subsequent saponification afforded the hydrocinnamic acids which were again converted to the expected aldehydes $R^1$-CH$_2$-CH$_2$-CHO by the previously described reduction/oxidation sequence (scheme 11).
Scheme 11: Preparation of hydrocinnamic acids and aldehydes \( R_1-\text{CH}_2-\text{CH}_2-\text{Cl}-\text{IO} \) via Heck reaction.

Aldehydes \( R_1\text{-O-CH}_2-\text{CHO} \) (\( X = \text{O} \)) were readily prepared according to the synthetic route depicted in scheme 12. Thus, alkylation of phenol derivatives \( R_1\text{OH} \) with methyl bromoacetate, and subsequent reduction afforded the alcohol precursors which could be oxidized under Swern conditions in order to obtain the expected aldehyde derivatives (scheme 12).

Scheme 12: Preparation of aldehydes \( R_1\text{-O-CH}_2-\text{CHO} \).

The synthesis of enantiomerically pure toluene-4-sulfonic acid (S)-methylcarbamoyl-phenyl-methyl ester is exemplified in scheme 13. Treatment of methyl (S)-(+) mandelate with an alcoholic amine solution gave the corresponding amide which could be converted to toluene-4-sulfonic acid (S)-methylcarbamoyl-phenyl-methyl ester after reaction with p-toluenesulfonyl chloride.
Scheme 13: Preparation of toluene-4-sulfonic acid (S)-methylcarbamoyl-phenyl-methyl ester.

Whenever the compounds of formula (I) are obtained in the form of mixtures of enantiomers, the enantiomers can be separated using methods known to one skilled in the art: e.g. by formation and separation of diastereomeric salts or by HPLC over a chiral stationary phase such as a Regis Whelk-O1 (R,R) (10 µm) column, a Daicel ChiralCel OD-H (5-10 µm) column, or a Daicel ChiralPak IA (10 µm) or AD-H (5 µm) column. Typical conditions of chiral HPLC are an isocratic mixture of eluent A (EtOH, in presence or absence of an amine such as TEA, diethylamine) and eluent B (hexane), at a flow rate of 0.8 to 150 mL/min.

3-(3,4-dimethyl-phenyl)-acrylic acid [general procedure for Knoevenagel condensation (GP1)]

A suspension of 3,4-dimethylbenzaldehyde (15.000 g; 111.793 mmol) and malonic acid (22.103 g; 212.410 mmol) in pyridine (85 ml) was heated to 50°C, under nitrogen. Then piperidine (8.5 ml; 86.079 mmol) was added dropwise (over 5 minutes) and the resulting suspension was heated to 75°C for 2h. The reaction mixture was cooled to 0°C, and
poured into an ice-cooled solution of concentrated hydrochloric acid (12 N; 96 ml) in water (1200 ml). The precipitated colorless product was filtered off, and washed with water (3 x 100 ml). Remaining water was evaporated under reduced pressure, then under HV to give the dried product 3-(3,4-dimethyl-phenyl)-acrylic acid as a colorless solid (19.230 g; 98%).

LC-MS: t_R = 0.88 min; [M+H]^+: no ionisation.

Filtration over a pad of celite, and subsequent concentration to dryness afforded a crude heterogeneous residue which was dissolved in DCM (100 ml), and water (50 ml). The organic layer was then dried over anh. MgSO₄, filtered, and concentrated to dryness under reduced pressure to give 8-[2-(2,5-difluoro-4-trifluoromethyl-phenyl)-ethyl]-3-ethyl-5,6-dihydro-8/-/-imidazo[1,5-a]pyrazine-7-carboxylic acid tert-butyl ester as a yellow oil (1.400 g; 94%). II. BIOLOGICAL ASSAYS

IN VITRO ASSAY

The orexin receptor antagonistic activity of the compounds of formula (I) and formula (II) is determined in accordance with the following experimental method.

Experimental method:

Intracellular calcium measurements:
Chinese hamster ovary (CHO) cells expressing the human orexin-1 receptor and the human orexin-2 receptor, respectively, are grown in culture medium (Ham F-12 with L-Glutamine) containing 300 µg/ml G418, 100 U/ml penicillin, 100 µg/ml streptomycin and 10% inactivated fetal calf serum (FCS). The cells are seeded at 80'000 cells / well into 96-well black clear bottom sterile plates (Costar) which have been precoated with 1% gelatine
in Hanks' Balanced Salt Solution (HBSS). All reagents are from Gibco BRL. The seeded plates are incubated overnight at 37°C in 5% CO₂.

Human orexin-A as an agonist is prepared as 1 mM stock solution in MeOH: water (1:1), diluted in HBSS containing 0.1 % bovine serum albumin (BSA) and 2 mM HEPES for use in the assay at a final concentration of 10 nM.

Antagonists are prepared as 10 mM stock solution in DMSO, then diluted in 96-well plates, first in DMSO, then in HBSS containing 0.1 % bovine serum albumin (BSA) and 2 mM HEPES.

On the day of the assay, 100 µl of loading medium (HBSS containing 1% FCS, 2 mM HEPES, 5 mM probenecid (Sigma) and 3 µM of the fluorescent calcium indicator fluo-3 AM (1 mM stock solution in DMSO with 10% pluronic acid) (Molecular Probes) is added to each well.

The 96-well plates are incubated for 60 min at 37°C in 5% CO₂. The loading solution is then aspirated and cells are washed 3 times with 200 µl HBSS containing 2.5 mM probenecid, 0.1% BSA, 2 mM HEPES. 100 µl of that same buffer is left in each well.

Within the Fluorescent Imaging Plate Reader (FLIPR, Molecular Devices), antagonists are added to the plate in a volume of 50 µl, incubated for 20 min and finally 100 µl of agonist is added. Fluorescence is measured for each well at 1 second intervals, and the height of each fluorescence peak is compared to the height of the fluorescence peak induced by 10 nM orexin-A with buffer in place of antagonist. For each antagonist, IC₅₀ value (the concentration of compound needed to inhibit 50 % of the agonistic response) is determined. Antagonistic activities (IC₅₀ values) of all exemplified compounds are below 1000 nM with respect to the OX₁ and/or the OX₂ receptor. IC₅₀ values of 51 exemplified compounds are in the range of 5-8671 nM with an average of 691 nM with respect to the OX₁ receptor. IC₅₀ values of all exemplified compounds are in the range of 2-396 nM with an average of 42 nM with respect to the OX₂ receptor. Antagonistic activities of selected compounds are displayed in Table 1.
Table 1. Antagonistic activities of compounds with respect to OX1 and OX2 receptors.
